Seeing, then, the necessity of appointing a sculptor, rather than opening a competition from which probably most leading sculptors would on principle hold aloof, the committee placed the commission outright in the hands of Mr. Thomas Brock, R.A.—to whose record I shall have to refer in a few moments—and they decided on opening a limited competition of five selected architects. On the winner would fall the duty of laying out the whole ground from end to end, and providing the architectural setting. They, therefore, determined on the names of three eminent architects in England, each widely renowned: Mr. T. G. Jackson, R.A., Mr. Ernest George, and Sir Aston Webb, R.A., all three of England—Londoners, in fact—Sir Rowand Anderson, representing Scotland, and Sir Thomas Drew, President of the Royal Hibernian Academy, representing Ireland.

Before we proceed to examine the designs for the memorial, it will be useful and interesting to see what has been done in somewhat similar cases by foreign countries and peoples. In this way, we here shall be equipped, according to our powers, to form a sound

opinion on the subject, and to judge how far—and, I may add, how admirably—this English scheme may compare with what has been done elsewhere, by the greatest artists of their day, by the most glory-loving and art-loving nations of Europe.

I take Russia first, and choose as the earliest of the modern royal and national memorials to put before you the colossal equestrian statue of Peter the Great in St. Petersburg.

It is not a Russian production, although made in Russia; it is the work of Falconnet—all but the head of the Emperor, which is by his daughter-in-law. The curiosity, the marvel, about it is, that although it weighed 16 tons, the statue is said to have been originally cast in one piece; and the balance of the rearing horse, supported on his hind legs and tail (which contains 10,000 lbs of metal) was wonderfully calculated. The pedestal consists of a block of granite weighing 1,500 tons, which was cleverly rolled from a neighbouring village to the spot on cannon-balls along an iron tramway. It was set up, you will recollect, by the Empress Catherine II., to the masterfulness of her great predecessor, in 1772, after taking 12 years to complete.

The column erected in 1832 by "grateful Russia" to the memory of Alexander the First derives it chief renown from being a monolith, and the greatest of modern times. The shaft weighs 400 tons. In one piece (as I have said), it is of red granite, 84 feet high, cut down from its original measurement of 102 feet, as it was feared that that enormous length was too dangerously great for its diameter of 14 feet. The whole, with the figure of the angel on the top, is 155 feet high, erected on its base—equally of one piece, and of red granite, 25 feet high. It also is the work of a Frenchman—of the architect, M. de Montferrand (the designer of St. Isaac's Cathedral), and was polished after it was set up. This rather foolish work cost not less than £400,000.

I say "foolish" because, for my part, I never could appreciate the idea of a mere column to the memory of any man, even if it has the virtue of being in one piece, and even if—especially if—it is crowned by a statue of the gentleman chiefly concerned; unless, of course, it is intended as a landmark, as is the case with the Napoleon Column at Boulogne. The figure cannot be seen. The shaft is an elongated cylinder—a poor shape when unsupported by others or by architectural forms; an opinion I venture to assert in the face of such precedents as Trajan's Column in Rome, the Vendôme Column in Paris, and the Duke of York's Column in London, where the figure is raised far above the chimney-pots and beyond recognition, with a lightning conductor through its brain! There is little or no invention, no play for artistic design, in such a device, in spite of a well-designed base. It is merely a stone pole, which perhaps to the popular mind is its chief attraction; for it gives no opportunity for thought or fancy in the designer, and consequently throws no strain upon the intelligence, or upon the artistic emotions of the man-in-the-street, or even the man in the town council.

The monument of Nicholas I. was erected in 1839. Seen from a distance, the rearing horse seems poor enough beside the fine massive proportions of the base, an enormous pedestal composed of granite of various colours.

Viewed nearer still, the proportions of the horse do not improve, and there is something to criticise on the score of taste in the details of the whole. The bas reliefs represent the chief episodes in the life of the Tsar, with four emblematical figures around the upper portion of the base, which are portraits of his wife and three daughters. Although the great lamp-posts interfere somewhat with the view, they add not a little richness to the whole.

The monument of the Empress Catherine II. was carried out by two Russian sculptors, Mikeshin and Opekushin, but the work was cast by an English firm in St. Petersburg—Mr. Baird's.

Set up in the Nevski Prospect, in front of the Alexander Theatre, it looks well when seen close; but at a distance its compactness tells against it, and the figure and the poor architectural base, with too little variety of outline and silhouette, tend to merge into a form like a hand-bell. Nine figures in high relief of Catherine's chief supporters in her government and reform are arranged in sitting posture around the pedestal. The female figure on the left is that of Princess Woronzoff Daschkoff, the first president of the Academy of Arts of St. Petersburg. Forty-nine feet is the height of the monument, which was unveiled with great ceremony in 1873.

Austria is not behind in the matter of royal monuments. The most important is that of the Empress Maria Theresa—an elaborate composition, in which the architecture and sculpture are well balanced—erected in front

of the Imperial Palace, and between the great twin museums built by Hasenauer, the architect who designed this pedestal. The sculptural portion is by von Zumbusch. The dominating figure of the Empress, in bronze, 19 feet high, is enthroned on the marble pedestal, 43 feet high. She salutes her people, and holds in her hand the Sceptre and Pragmatic Sanction —the symbol of unity of the Austrian Empire.

One of the defects of this imposing composition seems to me to be the variety of scales on which the various figures are designed. The ideal personifications of Strength, Wisdom, Justice, and Mercy, at the feet of the Empress, although life-size, look like dolls in comparison; and the equestrian figures, the isolated figures, and those in high relief, cleverly as they are arranged, tend by their different sizes to confuse the eye. This is a difficulty which Mr. Brock has successfully overcome. I show this enlargement in order to demonstrate the mistake of placing fully detached figures against a low relief in which they are in direct relation. Here we have a group of Eckhel, the numismatist, the historian Georg Pray, and Glück and Haydn—the former holding the child Mozart's hand—and, as we see, the shadow thrown by Glück's head upon the distant building helps to destroy the balance of the composition and confuse the whole. This work dates only from 1888, when it was set up by the Emperor Francis Joseph as a centenary celebration. It occupied altogether over 14 years, and cost £72,500. From these works, conceived in the conventional spirit, let us turn to more recent memorials in France, raised, in this case, not to a sovereign, but to modern statesmen, eminent and patriotic.

The monument to Gambetta in Paris is interesting to us for more than one reason. Raised to a great statesman, and so, I fear, not quite legitimately introduced here, it is a capital type of the silhouette much affected by French sculptors, and by other nations who follow them. This photograph is unfortunately disfigured in its *ensemble* by the wreaths, and by those very inartistic objects in street photography, men and women, appearing here in honour of the anniversary of the patriot's death; but it will serve. The statue of Gambetta illustrates conclusively enough the denunciation of the frock-coat in sculpture so amusingly set forth by that admirable critic, M. de la Sizeranne. The garment does not lend itself to poetry, whether in words or stone. The modern coat does not cover only, but masks and conceals the body, the beauty of which it ought to suggest, not only the forms but movements. Movements of the figure, the action of the wind, or action by the body, are all alike stultified by a coat, held by buttons which prevent not only proper play of the figure, but also of the natural folds which should follow every movement—that is to say, all the material for beauty in a human body and its action. Compare the fine action of a man—as of a Spanish or Italian peasant—throwing his cloak around him, with the ridiculous antics of one of us wriggling into his coat, and judge whether the illogical covering is not monstrous, artificial, unadaptable to the body, cylindrical in aim; in every particular opposed to the figure it clothes. And to ask a sculptor to represent the human form, clothed impeccably and photographically in its coat of to-day—to be, in fact, a tailor in stone—would be like expecting Ruskin to write his fine oratorical and poetic passages in the terms and with the flags of the signal-book.

It will be conceded that it is somewhat in this spirit that the modern sculptor has to deal with the frock-coat, if he is to deal with it satisfactorily and interestingly. We see here to what lengths the sculptor has gone to get variety; he has put his subject into a gale of wind. This lack of repose in the marble group, however, is partly intended to typify the fury of events, and the tempestuous career which form the background in which Gambetta's life is set.

The taste may appear to some a little strained in its details, but the effect is very fine, nevertheless, especially by the power given by the two bronze flanking figures, "Strength" on the left and "Truth" on the right; a form of composition, "elbowing-out," as it were, at the sides, giving power and grace, which we shall presently see again. The pyramid—a form on which Mr. Brock has determined for the Queen Victoria Memorial, though with greater restraint—is here somewhat emphasised; it is surmounted by the bronze figure of "Democracy"—a maiden representing the Republic, seated on the winged lion. Of this fine monument in stone and bronze, admirable in its architectural treatment, M. Aubé was the sculptor, and M. Boileau, the architect.

In the great memorial set up to the honour of President Carnot, by Henri Gauquié, the sculptor, and M. Naudin, architect, and recently unveiled, afer four years' preparation, in Lyons—the city in which he was assassinated —we have a design belonging to the class of

which the Gambetta in Paris is perhaps the most important example. This is weaker and more attenuated in design, and yet, being more complex in its lines, it is still somewhat imposing in its way. Side figures are again used to impart an air of strength and stability to the whole, and the parts are well imagined. The effort to get away from the tyranny of the coat, so characteristic of the modern French sculptor, is apparent here as in the Gambetta memorial; yet even the freely-treated overcoat has to be thrown back in order to afford a glimpse of the evening dress-coat underneath, or how would a Frenchman recognise a President? It cost only £10,000, of which £6,000 went to the architect and £4,000 to the sculptor.

Spain is hovering, hesitating, between the past and the present, and a very poor present, too. As an example, you have this, the latest effort of Spanish genius.

Perhaps I ought to apologise for putting it before you. It is the prodigious model for the memorial to King Alfonzo XII., now in course of execution and erection, by Senor Quérol, who is generally considered to be now the leading artistic figure in Spain, and is really an able man. But with this riotous spirit we can have no sympathy; there is here nothing of the dignity of sculpture, or of the repose of the death monument, which, however glorious, however turbulent, may have been the life and reign of the monarch it honours, though it represent the splendour, must always avoid the mere fuss of life. But why all this clang of glory? Was King Alfonzo—whose memory we all respect—so mighty a conqueror? We have a sculptural *tour de force*, in parts lamentably skilful, hopelessly unimpressive; a debased taste which we deplore when we recognise it in "Vienna goods" or "Articles de Paris," or even in wedding-cakes. This exuberant production would have been a constant regret and eyesore to every Spaniard who can still appreciate the dignity and true nobility of Velasquez and Spain; but I have recently ascertained that the cloud of horsemen mounting into the pedestal has been cleared away, and the low semi-circular screen has been enlarged and elaborated in imitation of Sir Aston Webb's by the clever architect, Señor Don José Riera.

Turning to Belgium, we come to her principal modern memorial monument, which has been erected in Laeken, to the north of Brussels. It belongs to the canopied series, and set up, as it is, on the summit of eminence 200 feet high—the Montagne de Tonnerre, it shows a somewhat better proportion perhaps than appears on the screen. This highly-decorated but ill-designed Gothic structure, which, to undiscerning eyes, may recall the spires of Cologne, is dedicated to King Leopold the First, the consolidator of the Belgian monarchy, a statue of whom, by Geefs, stands in the interior. The architect was M. de Curte. The pierced work, surmounted on the apex by a statue of St. Michael, imparts a lightness to what might otherwise have suggested the heaviness of an extinguisher; but yet we cannot be quite strangers to Ruskin's feelings, when he scoffed at Gothic church steeples set upon the ground.

Germany has a number of important monuments, and the most recent crop, if not exactly fine, is plentiful.

The first, and to my mind, still the finest of any, is the statue in Unter den Linden to the Emperor Frederick the Great, whose memory had to wait until 1851 for this act of tardy justice. Then Rauch was commissioned to execute this great bronze monument which is so original in idea, so excellent in effect, so good in light and shade, and so fine in its technical details of texture and finish.

"It is impossible," it has been said, "to realise, with such means, a more imposing work." When it was begun this monument was never intended to be so large and important—Rauch's sketch models prove that, and show how he modified and developed his first conception into what we now see. The statue itself (17 feet high) boldly endowed with the monarch's own peculiarity of dress—(the queue to the hair and the walking stick dangling from his hand) is a striking effigy. And the general arrangement of the granite pedestal, 25 feet high, is simple in its mass and excellent in design.

The great bronze groups represent, with the utmost fidelity to fact and likeness, the commanders during the Seven Years' War, in number thirty-one. There is, of course, a variety of scale here, too, in the figures, but it does not force itself upon the eye.

The equestrian figures (comprising Duke Ferdinand of Brunswick; Prince Heinrich of Prussia; General Seydlitz; and General Ziethen) are very cleverly introduced; the hinder quarters of each animal are cast in high relief—and the fore parts entirely detached in the round. This is a device which Rauch had previously adopted in his severely pseudo-classic statue of Maximilian

Joseph I. at Munich, where the four lions had been similarly treated by him in 1835—sixteen years before.

Up on the slopes of the Rhine, in the Niederwald, opposite Bingen, on the spur of a hill 740 feet high, stands the great national monument commemorating the founding of the German Empire in 1870 and 1871. It was designed by Professor Schilling of Dresden, and approved in 1877. It was inaugurated by the Emperor William I. in 1883. The architectural base is 78 feet high—roughly, about the extreme measurement of Mr. Brock's memorial from the ground to the tip of the Victory's wing. The enormous figure of Germania, symbolising the unity and strength of the Empire—is 33 feet high. The Eagle of Empire is a leading feature of the base, which is flanked by figures of Peace and War, between which is a great panel in high relief, containing portraits of King William of Prussia, mounted, and the other princes and generals; and below, are the figures emblematic of the Rhine and the Moselle. The monument cost £55,000, and occupied six years in execution. The vast proportions and heavy mass and outline of this noble work are adopted partly with a view to effect, as a great landmark in the surrounding country; an effect which is successfully secured.

A less impressive work is the Prince Bismarck Monument, which stands before the Reichstag Buildings. It is by Herr Reinhold Begas, the sculptor who for so long has had the special favour of his Sovereign, and who is held to be partly responsible for the Sieges Allee—the Avenue of Victory—which is the joy of Berlin, the joy of admiration in one half, and of scoffing criticism in the other. For although this continuous pæan of triumph is natural enough, the glory being great, it is thought by some that all this fanfare is apt to be a little too flamboyant.

The figure of Bismarck stands 6½ metres high—the scale wisely adopted for all the other figures—which seem to be so strangely detached from the principal feature. It will be observed how here, also, the sculptor has wrestled with the uniform, and how by dropping down the upper corner of the coat, unbuttoned, and by casting the skirt into horizontal folds by the drag of the sword-hilt, he seeks to modify the distressing inaction of the formless and unsympathetic garment. In front is Atlas, typifying the bearing by Bismarck of his own world, and some other peoples', upon his shoulders. To the left the sibyl, with her book, symbolises wisdom, and the helmeted maid on the right, statesmanship.

The back shows the figure of Siegfried, the all-conquering knight and craftsman, at work on his sword—a sort of early Nibelungen Bismarck. The sculptor, as on other occasions, has deliberately offended against, or, at least, departed from, what is sculpturally legitimate by making his figure get off the pedestal, and stand, as it were, among the public. He had done this before in his great fountains—the Schloss-brunnen in Berlin—and so has shocked the purists past all imagining. Whether the effect he has secured by this strange overhanging is worth the sacrifice is a serious question.

The sculptor, with his helpers, completed this memorial, after only four years' work, in the 70th year of his life.

Similarly, in the case of the statue of the Kaiser William the Great, in Berlin, utter failure attended the first competition, which, in 1888, attracted not fewer than 147 sculptors. At the limited competition which followed, the Emperor signified his preference of the work of Begas, who received the commission at the end of 1892. In Supply £400,000 was proposed in 1894, but the amount was cut down to £200,000; and as the unveiling was to be a centenary celebration the sculptor was ordered to proceed and to get the work done by 1897—by which date the Bismarck monument was awaiting him to execute. Feverish activity reigned in his studio. An army of clever young sculptors and students were at work under the master, on the details, and Begas centred his attention on the equestrian group of the mounted Emperor, whose horse, his favourite charger, "Hippocrates," is being led by "Peace"—of all people!

The statue is 29 feet high, or about 13 feet higher than Rauch's Frederick the Great. At the sides are the figures of "War" and "Peace," independently sprawling out of the composition down the steps, a trick—or perhaps I should say, an artifice—which is greatly affected by Begas. A closer view is instructive.

At each corner are "Victories" on globes, with flowers and wreaths. Projecting from the base are threatening, snarling lions—which the figure of "Peace" above cannot render reassuring—uncomfortably astride of bundles of banners and tattered flags, bayonets, gun-carriage wheels, cuirasses, helmets, cannon,

and shells in bristling confusion; and the emblems of the Imperial sovereignty trickle, as it were, down the front steps.

The colonnade behind is 260 feet long, and it is to be remarked, that of the series of important memorials we have seen, this is the first—and, with the exception of another to follow, the only—important work (besides the recent statue of the Empress Augusta) that is thus supported by architectural embellishment.

This monument, therefore, has importance for us; and in view of our great work that is to come, we are bound to criticise it. For we cannot but consider it spotty in light and shade—baroque in style—even fussy; as if it wanted some good, serious sculptor of refined taste and artistic restraint, to come and tidy it up. It has been described by a German critic as a "Siegeshymnus"—a "Hymn of Triumph." But it does not sing. It seems, in spite of its great qualities, to shout glory, if in rather a sugary voice—not in the simple notes of modest thankfulness, but rather in a "trample-on-your-enemies" tone of voice, with the motto, "Defiance not Defence."

In 1896 the memorial to the Empress Augusta was unveiled at Coblenz. The statue and the bas reliefs are in white marble by Professor Moes, of Carlsruhe, and the architectural portion by Bruno Schmitz, who occupies so distinguished a position in Germany. It is difficult to admire this work very greatly, but it aims at dignity and a happy union of the arts.

In Italy of late years monuments have been multiplied, and the chief of them have celebrated Garibaldi and King Victor Emanuel. That of Garibaldi, at Rome, erected on the Gianicolo, is by Professor Galloni. Although a national memorial, it does not seem a great work, in spite of fine passages; and the ultra-modern fighting groups at front and rear of the pedestal contrast oddly with the almost classic repose of the rest. Compare this equestrian group here with that on the Garibaldi monument at Milan and you will recognise a finer group, in which the tail of the horse recalls that in Alfred Stevens's unfinished model of the Duke of Wellington. This well-proportioned monument, with the fine figure of Italian liberty sheathing her sword, is by the sculptor, Ettore Ximenes.

They who think—there are a few, but not many—that a large sum ought not to be expended on our great memorial, should consider what is being done elsewhere in order to commemorate a great national hero and national event. To Victor Emanuel modern Italy owed her revival, her liberation, her consolidation into unity, as one great people and one nation, taking her place at last—after how great an interval!—among the great Powers of Europe. To him, it was felt, a mighty memorial should be raised—to him and to the Third Italy—and no sacrifice was thought too great to compass this end. The structure was to take the form of a vast scenic architectonic screen on the Capitoline Hill, and to provide for the inclusion of a great equestrian statue, to be led up to by flights of steps 27 metres high, which the sculptor, Signor Enrico Chiaradia, was to model. That group is now in existence, although I believe the plaster has not yet been cast into bronze.

In the first competition a hundred designs—all of them models—were sent in. In the second only six, to the first two of which a prize of £400 was to be allotted. The second prize was awarded to Signor Luigi Boffi for a design imposing for its size rather than by its taste (I am constrained to show these models by slides from wood-engravings as suitable photographs are not at present procurable). The little figures at the foot of the steps and on the first landing disclose the monstrous proportion intended.

The design of Bruno Schmitz, who was nearly successful for the Emperor Frederick memorial, and that of the Count Guiseppe Sacconi were bracketted first and each received the £2,000 premium. The series of steps in the case of the former seem to involve a terrible, almost a prohibitive, obstacle to any but the athlete and the man in training to mount near enough to the statue to examine it.

That of Signor Sacconi, who was at that time a young man of twenty-five, is of a finer aspect, and to it was finally awarded the commission. More elaborate than any we have yet seen, not so much as a structure as a series of structures, it was estimated to cost £360,000, but £320,000 were spent on the site, the substructure, and the preliminary operations. Although it was begun in 1884 it is by no means within sight of completion. Up to 1898 not less than £1,040,000 had been spent, and it is expected that before it is finished it will have cost £2,000,000 sterling. Of this sum, however, a good deal has gone, of course, in expropriations, and further expenditure has been incurred by the determination to vault over the interesting archæological remains discovered when the site was being cleared. A view of the sculptor's model may be more satisfactory

—the light and shade is better seen. Since then there have been numerous radical modifications, external and internal; the groups of sculpture in the open and in the Baldacchino, and the pan-Athenaic frieze, were for a time retained. Internally, there is the introduction of great vaulted halls below the marble terraces; and, externally, the suppression of the attic of the colonnade and the broadening of the frieze, the entablature being given a more pronounced monumental character. This drawing will show the great change which has taken place in the design in the lower story. The details, it will be seen, are pre-Palladian, and are based on more classic models. Against the aggregation of vast halls, marble terraces, and colonnades, rising one above the other, Chiaradia's gigantic statue-group will stand forth. The tiny figures indicated at the side of this reproduction from a watercolour drawing of the latest view illustrates the size and scale of the final work.

This is the tribute of impoverished Italy to her great King. To our greater Queen, wealthy England has as yet subscribed to her memorial but one-eighth part of the sum to be expended there, and so has crippled the whole scheme.

When we come to the statues and memorials of our own sovereigns we cannot help recognising how poor and commonplace in conception in the past has been the imagination which has produced them, to say nothing of the stinginess which has dictated the scale. Take the Bombay statue, which is said to be the delight of the Indian population as a whole. The statue of Queen Victoria, set up near the Telegraph-office, is by Noble, and was uncovered by Lord Northbrook in 1872. It is in white marble, and the pedestal and canopy have perhaps the chief interest; but the whole of it including the statue, as I have already remarked, is said to impress the native mind enormously. It cost 182,450 rupees, nominally, that is £18,250, of which the late Kande Rao Gaekwar contributed £16,500. This was for a long while the chief statue of Queen Victoria in India.

If such is the effect on the native mind, how will the population be impressed by the sight of the mighty memorial which India is about to erect to the glory of Queen Victoria, from the designs of Sir William Emerson. Subscribed for by the Indian public, by English residents, and by the native rajahs, who contributed munificent donations, this great building, erected on the Maidan in Calcutta, is estimated to cost not less than £350,000.

The building, faced entirely in white marble, Greek and Indian, is 340 feet long and 225 feet broad, and is raised 12 feet high on a terrace 35 or 40 feet wide that entirely surrounds it.

Italian Renaissance in style, with just a *soupçon* of Oriental flavour in the treatment of the domes and in certain details, the building is finely planned—in the form of a capital H—and contains Durbar, Queen's Hall, and Prince's Hall, with picture galleries, sculpture galleries, and galleries for the display of arms and trophies. It is led up to by a grand flight of steps, at the head of which will stand Mr. Frampton's statue of the Queen. The corner towers are 30 feet square, and the dome, 70 feet in internal diameter, is about 170 feet to the top of the gilded figure of "Victory," which surmounts it.

Beneath it is the circular Queen's Hall, lined with white marble and panels of the marbles of India; so that, in the middle of a beautiful and spacious park, there will rise the glittering marble structure upon a terrace of white marble, with the snowy dome soaring into the air, and visible from every point of the river and the Maidan.

What have we done in Great Britain as national, not as municipal efforts? We have the George III. in Waterloo-place, which was originally designed by M. C. Wyatt at the command of the king, as a "St. George and the Dragon" and which, on the monarch's death, was actually altered by the Government's order—a brilliant idea—from the saint to the king (by judicious addition of costume, exchange of helmet for periwig, and so on, and the removal of the superannuated dragon), and there is Tribute No. 1 to a deceased British Sovereign.

Then we have the Albert Memorial—a better thing than many are willing to allow, though greatly harmed by the poverty of many of its details and by the coldness of the invention. It merits more attention than the rest, for, whatever may be said of it as a whole, it was a very sincere effort to do the best that could be done, with the help of the men at the top of their profession; and it was by far the most costly monument which had ever been put up. Only £60,000 had been subscribed by the public—and that was the amount paid to the trustees whom the Queen had appointed. £500,000 were voted by Parliament. Sir G. Gilbert Scott, the architect, was paid his commission on £100,000; and so far as the archi-

tects were concerned, the prime cost of the monument was £142,916. The gilding of the spire alone cost £10,000, and Queen Victoria spent a very large sum out of her privy purse before the work was finished. She had originally desired an obelisk, but a suitable piece of granite could not be obtained; perhaps, too, she hesitated at the cost (you will remember that the Alexander column at St. Petersburg came to £400,000); but when it came to embellishing the Memorial, the Queen did not stint the cost, whatever it might be, in doing full honour to Prince Albert's memory.

There had been a limited competition, in which P. C. Hardwick, R.A., G. Gilbert Scott, R.A., Charles and Edward Barry, James Pennethorne, Professor Donaldson, and M. Digby Wyatt took part.

Scott's work was selected: it was not really one of Ruskin's "Gothic towers upon the ground"; but a copy of the Baldacchino, or rather of the true canopy over the altar at the east end of S. Paolo fiore le mure in Rome. It also resembles that in St. Cecilia, and in the Anjou tombs at Naples as well. The flèche is built at the intersection of the groining on a steel-girder gridiron flooring, which perhaps hardly shows the architect to great advantage beside Kemp, the untaught designer of the Scott Memorial, which requires no iron supports whatever in its valid construction. We must not forget, however, that iron ties are used freely in Gothic architecture in Italy and elsewhere—even in Westminster Abbey. But Scott did not choose to expose them.

The enormous mosaics were all designed and executed by Mr. John R. Clayton, who, since the failure of the gold, has recently succeeded in inventing a method of completely coating his tesseræ in glass, so preventing the gold from perishing from any cause whatever. It was he, the young friend of Gilbert Scott, who suggested, for the groups that were to be placed on the four awkwardly-exposed bases isolated from the monument, the appropriate subjects of the four quarters of the globe as emblematic of the Empire; and, on the same evening, being challenged, made a sketch for each. He saw that a great core was wanted for each group; and so introduced the biggest animal in each continent—the bull, elephant, camel, and buffalo. P. Macdowell, R.A., took "Europe"—very poor in design; Foley, "Asia"—a more scholarly arrangement; W. Theed, "Africa"; and John Bell, "America." Of the other figures, "Commerce" was entrusted to Thomas Thornycroft, and "Engineering" to John Lawlor, and the great frieze of figures in the Podium were carried out by Mr. Armstead, R.A., J. Birnie Philip, and Calder Marshall, R.A. The whole of the sculpture work is in Sicilian marble. The "Spire" is 175 feet in height. The work was begun in 1864, and was unveiled by Queen Victoria—without the seated figure of the Prince by Foley (that by Marochetti having been rejected)—in 1872; four years later the statue was completed, and the whole unveiled in 1876.

With these works before our eyes, and with these details of cost and periods occupied in construction, we are now in a position to judge of our new National Memorial, and of the designs submitted by the competitors.

These designs were produced under what might be called the "conditions" of the competition. These were merely verbal, and sufficiently wide and vague to avoid hampering the architect in any way. No estimate of cost could be suggested, as it was not known what amount would be subscribed. A plan of the Mall was provided; a suggestion made as to the designing of a processional road, opening out at the eastern end; with an architectural setting for the monument; with a necessary laying-out of the ground on the west; and with the further statement that Mr. Brock would design the monument, to which the architectural structures in the west would necessarily be subordinate. Mr. Brock then met the architects in council, and explained his ideas by the rough model he had made. In July, 1901, the announcement of Sir Aston Webb's success was made, and at the end of October an exhibition of all competitive designs was held in St. James's Palace, for the public to judge of the rightness of the committee's verdict. That there was much to be said for each individual design was but natural, in view of the great skill and eminence of each competing architect, each in his own line and in his own country; but there is no doubt that the general feeling has cordially endorsed the finding of the committee, and applauded the approval of His Majesty the King.

What these various designs are I now proceed to show, for without them it is difficult to appreciate to the full the merits of the winning work. Mr. Brock's monument I keep for the end. It is necessary that a few plans should be shown in order to make the dispositions clear. I begin with the contribution from Mr. T. G. Jackson, R.A.

Mr. Jackson would leave a delta at the east end, taking a centre line through King Charles I.'s statue to a point in the processional road opposite the north-west corner of the present Admiralty building; but he begins his real design just west of the steps of the Duke of York's Column. Here, to harmonise with this structure, he would have erected a magnificent triumphal arch, of imposing proportions and severe and noble design. The Marble Arch is, roughly, 43 feet high; the Wellington Arch, 62 feet. Mr. Jackson's stately design is 93 feet to the top of the cornice of the main order, and to the top of the finely-outlined bronze group is 120 feet.

The central *allée* is not a roadway but a public walk, 40 feet wide, the public carriage roads being north and south. The pathway would be flanked by grass plots, intervalled every few yards by a semi-circular *exedra* containing a statue. Mr. Jackson provides railings throughout the entire length which could be closed at night, as a protection against the vandalism to which neither London nor Berlin is a stranger.

The forecourt or square is a beautiful feature. It is enclosed by colonnades and contains gardens, fountains, and groups of sculpture representing the colonies and dependencies of the Empire. The colonnade has at its angles four pavilions with bronze groups representing arts and industries.

In the middle of this *parterre* the monument of Queen Victoria would rise, and the general aspect is in fine keeping, and characteristic of the brilliant artist who designed it.

Finally, it will be observed, Mr. Jackson is the only one of the competitors, besides Sir Aston Webb, who carries the traffic *outside* the forecourt or square northwards to Constitution-hill and southwards to Buckingham Palace-road.

In Mr. Ernest George's interesting plan, also a delta, aligned with the Strand, leads to a beautiful and imposing five-way gateway, full of simple dignity and elegance—a form novel as a triumphal arch, erected at the north-west corner of the Admiralty building; and six groups of statuary are allowed for along the processional road.

So far the arrangement is quite simple. The forecourt before the palace is very large—longer then is suggested by any other of the competitors—extending as far as the corner of Stafford-house. On an elongated *parterre* the monument is erected, and east and west is a low gushing fountain. Groups of four columns with entablatures carry statues at the sides, and provision is made for equestrian statues north and south. A high wall from the water leaves space for a formal quay-path round the west end of the ornamental lake, and at the east the forecourt is bounded by a semi-circular screen, consisting of a double colonnade with domed pavilions at intervals. The whole is highly refined and graceful, as would be expected from this distinguished architect.

Sir Thomas Drew, of Dublin, President of the Royal Hibernian Academy, recognising that the line from the Strand to the Palace is at present deflected at a point near the new Admiralty building, boldly strikes a new line, involving the re-alignment of the whole Mall with the monument as the axis. And he would have substituted a palisade of architectural dignity for the rather disfiguring frontage of the low line of buildings in front of Carlton-house-terrace.

Entering from the Strand, we find an approach, 110 feet wide, flanked by buildings stately in intention, leading to a curiously high triumphal arch which forms a monumental entrance to the great memorial avenue.

But the main feature of Sir Thomas Drew's design is that, apart from the enormous *parterre* 300 feet in diameter, he boldly tackles the façade of the Palace itself, and on that—insisting on it as the background of the monument—he lavishes most of his effort, and of the funds at his disposal. The front of Buckingham Palace, built in 1842, is universally condemned as a poor and undignified, not to say a shabby and incongruous, performance—unworthy, as the residence of the Ruler of our great Empire; and unworthy, also, as a background for the memorial. Sir Thomas Drew's idea was to re-cast the façade architecturally, in the decorated Renaissance style, without changing its fenestration or altering the internal arrangement, by applying a Corinthian order elevated on a rusticated or coursed basement, as an improvement on the present lowest storey. His design provides for raising pavilion-blocks one at each end, thrown out from the building like great wings—which would cast shadows to break the monotony of the erection. A serious objection to this, however, appears to be, that he would thus inevitably block out oblique views from many of the windows of the Palace. The whole, the architect estimates, could be done for about £100,000 or £120,000. But according to the terms of the competition the Palace was to be left out of account.

Sir Rowand Anderson, of Edinburgh, simplified in his design the Buckingham Palace end into a large semi-circular plateau, surrounded by a balustrade, edged with statues of great men of the Victoria era, with a small garden and fountain at each re-entering angle. By what was doubtless a misunderstanding he produced an elaborate symbolical design for the monument itself, of which, I understand, he had a model very carefully worked out at Messrs. Farmer and Brindley. As the commission for this had already been given to Mr. Brock, and architects were invited to conform to his ideas, this was outside the scope of the competition.

A great arch was to be erected at the north-west corner of the present Admiralty buildings; and there the design ends, a non-architectural opening thereafter debouching opposite King Charles's statue, without any special features. This structure is an elaborate two-storied triumphal arch, Renaissance in style, designed for an equestrian statue, either of the Prince Consort or the Duke of Wellington, in the upper arch. The traffic could pass round as well as through, as in the case of the Wellington Arch and the Marble Arch.

We now come to the accepted design, the design of Sir Aston Webb. This was generally held to comprise the greatest number of the best and most practical ideas. A fine and eminently practical opening to the east, with good vistas and generally symmetrical system; the relatively modest and quiet *ensemble*, well-calculated to be a setting to the monument, and not unduly to vie with it; the appropriateness, practical and ornamental, of the design, from beginning to end—especially with the modification now introduced—these are the merits which have secured general support to the Committee to whom fell the difficult task of selecting among the fine designs of several of the leading architects of the day. Sir Aston Webb is credited with having the widest experience in laying out plans on a large scale, and, in such work, in harmonising as it were, the claims of the artist with the needs of the public, having regard to the exigencies of the circumstances.

He, like the rest, seems to have rejoiced in the opportunity, rare in England, of bringing a fine road straight up to the great feature to be viewed. Although abroad everyone recognises this simple and, one would think, this obvious truth, in England it is consistently ignored even to the present day. Abroad, the road leads up to the monument, or palace, or view; in England, as Wren pointed out, we approach them sideways. You cannot drive straight up to Whitehall, to the Mansion House, the Bank, or to the Houses of Parliament (at least you could not when they were built), to Somerset House, the British Museum, and see them from any approaching roadway without turning your head. St. James's Palace was one of the only buildings which could be fairly driven up to; even the recently erected Law Courts and the Albert Memorial are passed by sideways on the road, and you look at them, as it were, with one eye.

It was evident that if the processional road was carried straight with the view to making an outlet on the east, Drummond's Bank would have to be acquired and removed at the cost of some £150,000 or even more, and for what? to open obliquely into Whitehall, ending nowhere, and revealing a view of a gigantic specimen of excessively commonplace architecture. [I show an enlargement of the right-hand, or eastern section of the plan, so that you can see better.]

Now, by taking the central axis of the West Strand—having in mind the noble effect of a fine view from that great thoroughfare—and letting it intersect with that of the Mall, Sir Aston Webb obtained a point just behind Drummond's Bank, where he masked, more or less, the change of axis by a large circular "Place," in the centre of which he proposes to have a statue of Queen Victoria at the time of her accession (a felicitous notion), so that the figure of the Queen at the commencement of her reign, begun in hopefulness, looks towards the end of it, accomplished in splendour. Large spaces were equally to be left opposite Waterloo-place and Marlborough-gate (to which I will more particularly refer in a moment), until after passing along a series of statuary, at the west end we come to the great central feature of Mr. Webb's design, the details of which have latterly been considerably modified, to meet the practical requirements and demands of the authorities. I now show the elevation of this plan.

It is, of course, part and parcel of the whole laying out. The careful and thoughtful planning of the whole, the approaches from Constitution-hill on the right and from Buckingham Palace-road on the left, admirably symmetrical and in all respects monumental, the large opening into the forecourt from the Mall as well as north and south, through which an unimpeded full-face view of the monument may be obtained, must strike everyone at a glance. There are

fountains inside the colonnade, steps down to the water, and the monument is backed by the great screen.

But subsequent modifications, shown on the screen, were several. The outer roadway is now abolished and the traffic is taken inside the great forecourt, in order that the people should not be banished so far away, doubly screened from the Palace, and that the gaiety of the traffic and the contiguity of the passers-by might be retained. The finely-proportioned double colonnade has therefore been brought up to the water edge, where the pathway now is; the present balustrade, as you can see it any day, was to be but the first course of the outer part of it.

The two series of steps leading down to it from the water were suppressed, so that a finer effect is obtained by a retaining-wall, unbroken by this incident; and the broad steps have also been abandoned; and, as at present arranged, the charming vista of the distant Foreign Office—the more charming for being distant—and of Westminster, has been secured.

The high architectural screen, consisting of a colonnade behind the monument, is superseded, as it might have interfered with the view of Mr. Brock's work. It is now replaced by a lower, but still a very effective, railing or balustrade nearer to the Palace. It had been feared that the original screen, together with the outer colonnade, would to some extent have cut off the view of the outer world—of the Mall and the park—from the windows of the Palace. But as may be seen in this early sketch from the Palace windows, this would not be the case, or at least only in part from the ground floor, which in palaces does not count. In looking at this view, you must bear in mind the modifications which Sir Aston Webb has since made.

To see just what these are, we must revert to the later plan; but for the sake of clearness I take it in sections—the Whitehall end first.

Here, as the Government could not give sufficient space for the great circus opening out into Whitehall, the architect reduced it in size and brought it westward by the length of its radius. Space is thus given for the erection of a large Government building of a decorative and monumental character, and on each side of it, as now intended, a circular "place."

This new building—which will probably be devoted to Admiralty purposes, for this first plan shows a bridge thrown across to it—would be crescent-shaped on both its faces: on that to Buckingham Palace and that to the Strand; so that the slight irregularity of its site and of its alignment should be entirely masked; and, as it will comprise a great monumental archway in the middle, the triumphal arch originally talked of is thus obtained, and the processional road ends worthily, for a utilitarian government, with a public building. This sketch scarcely does justice to the design.

The correct plan of this building is shown. From that point, westward, the processional road, as far as the space opposite the Duke of York's Column, is narrower than the rest, owing to the exigencies of the ground available. Between there and the memorial itself, the measurements are vastly more imposing. Two rows of trees were removed and set back so as to obtain a roadway 65 feet wide. Few of these trees were of any growth, and had never really flourished; and they have been replaced by younger trees, carefully planted in abundance of rich soil—in spite of which, however, all have not survived the transplanting. There will now be, therefore, the same number of trees as before—an important point, about which the public rightly showed itself much concerned.

The width, then of the chief roadway is 65 feet which, in the circumstances—in relation to its length and to the traffic—does not compare ill with the 90 feet of the Champs Elysées. That is to say, it is here 80 feet between the trees, as against 90 feet between the trees of the Champs Elysées. On each side is an alley of trees (with paths between), 25 feet wide—which form vistas, as it were, and are intended to be furnished at each break with groups of sculpture. These alleys flank the processional road. The road at the north is made into a riding road; but the southern one has been greatly restricted through the desire to avoid encroaching more than is absolutely necessary upon the public park.

Proceeding west, then, we arrive at the open space at the foot of the steps below the Duke of York's Column. As in Waterloo-place, above, are statues to our Eastern heroes, so the space below, by a continuity of idea, was to be devoted to the glorification, by means of emblematic groups, of the Eastern Dominions.

Thus, facing the steps at the north-east corner of the park, there will be two handsome gateways, and between, an important group was provided for, symbolical of "The Genius of the Orient;" and the four subsidiary

groups of statuary to represent Ceylon, Barbadoes, the China Ports, and India.

Opposite Marlborough-gate, provision is made for another handsome gateway into the park, and the "Place," 100 feet across, was to be embellished with statuary representing the Western Dominions, comprising Australia, Canada, New Zealand, and Newfoundland. (The nomenclature and classification, though happy, seem to me, at first sight, a little arbitrary, geographically speaking.)

At the western end of the processional road, nearest the Palace, are the two groups of statuary, representing South Africa, the Cape, and Natal. This is the view seen from Birdcage-walk.

It should be added that the present hideous and foolishly designed electric-light standards now set up, which have rightly been made the subject of public protest, are merely temporary. The lamps will be an important feature of the general design. Close around the monument itself, upon its platform, will be lights, about which I shall say a word presently. Mr. Brock puts eight incandescent lamps on the pavement around it, not shown in the view. On the outer side of the road are six groups of lamps, each consisting of a cluster of five each, within the semi-circular recesses, probably to be backed by a low stone parapet. The lamps, be it noted, are Mr. Brock's special charge, and will be in stone and sculptured bronze. I have seen the proposed design, which promises to be a revelation to the Londoner.

Thus, there will be three circles of lights which will mark the construction; and these, together with the lamps along the stone balustrade enclosing the forecourt in front of the Palace (which balustrade will be 10 feet high), will produce a very fine effect at night.

Finally, it should be observed, that there is a direct open approach to Mr. Brock's monument from the Mall from between imposing piers; another from the south, that is to say, from Birdcage-walk, whence a view of one of the finest groups will be afforded; and, similarly from the north; another, by a tree-skirted *tapis vert*, a grass-planted avenue of the same width as the main roads—65 feet, which extend northward in the Green Park, so bringing the monument directly into touch with Piccadilly. And it is approached by handsome gates and piers, now in the course of erection. These will be surmounted with handsome figures of boys instead of the usual urns.

It will be seen that Sir Aston Webb has adopted a style of quiet and unpretentious classic type, dignified and harmonious, and sufficiently monumental. The whole is admirably and consistently planned, in complete sympathy with the work of the sculptor; and the result of this cordial collaboration was to be a vast work of decoration, now unhappily much curtailed, but which will still be a splendid ornament of London, and a worthy bequest by the twentieth century to the London of the future.

I now come to the work of Mr. Brock. I may be permitted, first, to refresh your memory of some of the chief works by the sculptor, who was selected without the formality of a competition to carry into execution this great work. In 1866, Mr. Brock had entered the studio of Foley, and when his career was well assured, he had the rare courage, and elasticity of mind and spirit, to modify his style in accordance with the newer current of artistic thought and feeling, and so developed, he left his master far behind.

His first important ideal work that marked his transition was "A Moment of Peril"—a fine scholarly group, soon to be surpassed in technical quality and refinement of taste. This we see in "The Genius of Poetry"—graceful and reposeful where the other was violent in action and passionate; sculpturesque, where that was, in a measure, romantic and anecdotal. Then a higher point was reached in "Eve," so touching in attitude, and so human in the sentiment of remorse—just a fair, shamed woman, purposely not endowed with that conventional perfection of beauty with which the first mother is by artists commonly endowed.

In portraiture, Mr. Brock has been similarly successful. In "Dr. Philpott, Bishop of Worcester," there is not only striking likeness. It is admirable and characteristic in pose, solving the eternal problem of the upraised arm, and showing an admirable and refined treatment of drapery, with its shallow depressions, without black holes of shadow, and its expressive crispness of the edges. "Sir Richard Owen" shows similar handling and a complete mastery of the figure and, above all, of character.

In striking contrast with these is the "Edward the Black Prince," the colossal work lately set up in Leeds, where it is far more imposing in effect and colour than when it was seen, gilded, like Falguière's "Joan of Arc," in the quadrangle of Burlington-house. It seemed

curiously significant that a well-known writer, animadverting upon modern sculpture, found fault with this group on the simple ground that it was not the equal of Verrocchio's "Colleoni" in Venice, the most magnificent equestrian statue in the world.

Then we have what is perhaps Mr. Brock's masterpiece, by which the memory of Lord Leighton is to be kept green in the aisle of St. Paul's Cathedral. Admirable in proportion, in harmony of design, and line, and in silhouette—in conception, sentiment, and detail—this is a monument in which the President himself would have rejoiced—for all is beauty, dignity, and repose.

But when Mr. Brock was still a young man he had produced a monument of an important and elaborate character. This is his "Daniel O'Connell" in Dublin, in which he showed a richness of design and a certain stateliness of line and character that might be based upon foreign monuments we know abroad, yet still impresses us as one of the finer out-of-door monuments in Great Britain.

But a work, more appropriate to the subject in hand, and necessarily more sweet and tender in feeling, is the bust of her late Majesty, Queen Victoria—one of the noblest, most dignified and exquisite works of its class in England—full of tenderness, delicately and lovingly rendered. Carried so far that the marble almost breathes, it remains sculpture, free from trick. And the whole is a most finished and beautiful rendering of the Queen at her best—elegant, thoughtful, wise, and solemn.

These, then, are a few typical examples of Mr. Brock's work, which, if not completely representative, are sufficient to show the high achievement and the calibre of the man whose sketch-models we are now to see. Hastily summoned to make a sketch, without delay, for the King to consider, he thought out and produced within three weeks this rough clay model of what he proposed for the central feature. [The little figures on the steps are intended to show the scale.]

The final model is now completed in all its parts—as you have probably seen in the winter exhibition of the Royal Academy—but as it is a model, you must not judge it as a finished work. The artist, exercising a wise prudence—and as a precaution against eventualities such as the world has had such bitter experience of—has determined to complete the models for the whole undertaking, before he begins a single touch on the actual work itself. I must warn you that it is in the staring white new plaster, photographed in the studio—so that we cannot fairly judge of the effect of the work as it will be. I show the central figure first. It is on a one-tenth scale, so that this portion of the monument, the model being 7 feet 6 inches high, will be 75 feet from the steps at the base to the tip of the Victory's wing.

The idea is, the Great Queen—seated amid the personifications of the personal qualities that made her great. At the right is a group representing "Justice"; at the left, "Truth"; and at the back "Motherhood." Above are "Courage" on the right, and "Constancy" on the left—qualities which, with the others, bring about the triumph of "Victory"—"Victory" which surmounts and dominates, as it were, the whole structure of her virtues, and crowns her glorious reign.

Around the base are freely-treated ships' prows—two bearing trophies suggestive of the Army and Navy, and two, fruits and flowers, emblematic of Commerce and Prosperity.

Above the slightly pyramidal core, at the feet of "Constancy" and "Courage"—appears an Eagle—the "Eagle of Empire," a most valuable and felicitous architectural form.

It has been objected that the eagle, really an heraldic badge, is not, in fact, an imperial device at all; as it is the common symbol of the American Republic and the Kingdom of Prussia. I do not think that the objection is sound, as the eagle was, to go no further back, the emblem of the Roman Empire, as it has been, in modern times, of the empires of Russia, Germany, Austria, and France; and even republics and kingdoms can be identified with empire; a claim, surely, which will not be denied to Great Britain.

As a few details of the monument should be examined, I shall, as it were, turn the work round for you. In the group of "Justice," which we must recognise as quite admirably composed, the winged figure of Justice holds the sword and protects the weak; while the boy, ever young, bears the scales. The emblem of the lily appears on the pilasters.

We here have the full view as seen from the Green Park. It shows well how the figure of the Queen exceeds in scale all the others, in a just proportion.

"Motherhood" with its chief figure, embracing two of her children, while the third is on the ground, is a tender composition, excel-

lently treated and full of charm. This the view from the Palace.

In the group representing "Truth," the genius holds the mirror; the palm branch is grasped by the child, the personification of truth, and the seated figure searches for truth in the written word.

"Constancy" and "Courage," which in their power and handling seem to suggest Alfred Stevens, form a fine base at the feet of "Victory" on her crystal globe. "Victory," it should be observed, not exultant over crushed and fallen enemies, but, pointing Heavenwards, triumphant over all that is unworthy, mean, or foul in character and conduct.

This portion of the monument will probably be in bronze gilt; the rest, of white Carrara marble, or, it is to be hoped, of some finely-toned stone. The figure of the Queen, which, as it sits, will be thirteen feet high, is draped in her robes of State—the only statue, I believe, in which the seated Queen wears her robes from the shoulders. The drapery is finely disposed, and the whole figure has an imposing and impressive air as it projects from the architectural throne and niche, with its rose-decorated pilasters. Allow me to repeat that these photographs are only from plaster models, and that the figure of the Queen in this model is not more than 15 inches high. This model is now in course of being enlarged to five times this size—that is to say to one-half the full, final size, as it is not safe to enlarge at once from the model to the enormous proportions it is finally to take. Even this half-size is considerably above life-size, and it is being elaborated with all the minute care essential to so important a work.

In order to show you how the work is progressing, I place before you a view, taken last week in Mr. Brock's studio, of the panel to one of the fountains, representing a water-nymph. This is a detail, of what might be called of secondary importance, and is, as you see, still in the clay and not yet quite finished. Yet the length of the nymph is not less than 12 feet.

The general view shows the monument on its platform, 70 feet wide.

At each side is a great fountain, discharging down steps into a basin 160 feet long and 28 feet across. That on the right typifies "Power," and the figures, which, in the manner of Michael Angelo's Medici figures, preside over the fountains, personify: the male (with a helmet), the Army, and the female (with a ship), the Navy—the foundations of the monarchy. The sea-nymph which you just saw is below, in the panel—colossal in size; and on the right and left are bronze reliefs elaborating the idea of the two Services. The parapet is 8 feet 6 inches high. The little figures standing at the edge are of the size of life, and are modelled to scale.

Corresponding with this *motif* of "Power," we have, on the other side, "Intelligence" (which quality presumably is not denied also to the Services). Here the two figures represent: the male, with the dynamo, "Science," and the female, with the palette, "Art;" a Triton reclines below. The reliefs here have for their subject the "Progress of Science and Art." The water, it should be explained, is obtained from the overflow from the Serpentine, and will be running day and night, and thence fall into the ornamental waters of St. James's-park, below.

Around the main parapet, between the monument and the fountain-basins, fine bronze lamps, it is at present intended, will be erected; but whether these will be short and richly massive, or tall and elegant, has not yet been decided. To my mind, the short ones will interfere less with the view of the monument itself.

Around the central feature, four statues accompanied by lions will be erected. In front, on the left is "Progress"; on the right "Peace"; and at the back, on the left, "Manufacture," and on the right, "Agriculture."

The pavement, so important in the case of a monumental undertaking such as this, is usually neglected in England; irregular stones and narrow kerbs often mar the effect which abroad is always carefully considered. In this case it is hoped that the pavement will be composed of sawn grey granite slabs. Outside the monument 25 feet has been left for the side-walk. If that pavement and the whole of the monument could be raised 24 inches and reached by three steps, the effect would be very fine. But it would mean 1,800 feet of triple granite steps, and that is an expensive item.

Then there are two other important features. In the middle of each section of Sir Aston Webb's semi-circular screen, showing inwards, is a pavilion before which Mr. Brock erects two elaborate fountains, of which the designs are not yet sufficiently advanced to be placed before you. The subjects are Empire and Progress, and gushing water will make a continual play of light and sound, and add

gaiety to the grass and flower-planted enclosure which Sir Aston Webb prettily calls "The Queen's Garden."

Now, it has unhappily been quite recently decided that the funds available do not permit of the larger scheme being carried into effect. I am informed that the series of sculptures in the processional road are to be suppressed; and as the colonies contributed considerable sums, the gates with the armorial decorations of arms and emblems of those colonies and the sculptures facing them on the side fountains, will be set up in their names, with a bronze plate to record their respective participation. Thus, the Mall side is allotted to Australia—that on the north (facing Piccadilly) to Canada; the entrance from the processional road, to South Africa; while, of the great fountains in the quadrants—that to the south-east will be in the name of West Africa and the Indian Dependencies, and that to the north-east to Newfoundland and the West Indies.

Speaking for myself, I am of opinion that the comparative failure of subscriptions ought not to be allowed to cripple the great scheme as it was finally passed, and if the contributions are not sufficient Parliament should be moved to make it good—£10,000 or £20,000 a year for five years—though it might wring, would not break, the heart of the Chancellor of the Exchequer. The occasion is unique; and the object one which would appeal to the nation at large.

The whole work, it is satisfactory to know, is to be carried out in the finest and most enduring materials, both the sculptural and architectural portions. Twelve thousand cubic feet of marble will be required for the main feature, and, if the fountain basins are lined with marble, 7,000 feet more. The numerous groups of sculpture on the processional road, representing the various Colonies and Dependencies, were to be under the full control of Mr. Brock, who, it was arranged, would place the commissions for them amongst our most competent young sculptors, and, being responsible for them, would, of course, retain control and see that they should harmonise in design and in spirit with the general scheme.

The one unsatisfactory feature would be the retention of the present commonplace façade of the Palace. It is, as Mr. Statham so vigorously puts it in *The Builder*, "a miserable anti-climax. Nothing can get over that. Give the Palace a new front, or the whole thing is lame and incomplete." Now, Sir Aston Webb has aimed at some improvement of the sky-line by placing Mansard roofs on the centre and the ends of the east front; but that is not enough. Now that we have a magnificent Processional Road—one of the finest in Europe—to lead up to the Palace, we ought to have a fine Palace for this magnificent Processional Road to lead up to. When that is done, we shall have performed our task completely, and paid the tribute of our homage to Queen Victoria.

Such, then, is the monument to the Queen; a design, if it be carried out on the grand scale originally intended, so finely conceived, that even those who are familiar with what has already been done upon the ground can call up but a mere mental sketch of the imposing aspect of the completed work as it was designed. It may be finished in five or six years. It may seem a long while; yet it is but a brief space compared with the 12 years of the Albert Memorial, the 27 of the Nelson Memorial in Trafalgar-square, the 20 years which have been expended on the Victor Emanuel Monument, with so slight a present showing for it. The years will fly—all too soon for most of us—and, whatever be the outcome, we shall see a memorial worthy of the artists who fashioned it, not unworthy of the nation who raised it, or of the great and noble Sovereign whose memory it is designed to honour.

DISCUSSION.

Mr. SIDNEY LEE said that he had listened with very great interest to the paper. All must regret that owing to want of money, the full design was not carried out, and he cordially sympathised with what the author had said as to the desirability of Parliament and the Chancellor of the Exchequer coming to the rescue of Mr. Brock's and Sir Aston Webb's efforts.

Sir CHARLES LAWES WITTEWRONGE, Bart., remarked that the only point which had struck him in nearly all the views that the author had shown was that the sculpture had been too large for the building, and he thought that was also the case in the Queen Victoria Memorial. It swamped Buckingham Palace—not that much mattered—but still as a question of art, the memorial should be subject to the buildings which were behind. In the case of Berlin, also, the sculpture was a great deal too large for the buildings.

Mr. ALFRED EAST, A.R.A., thought the members were very much indebted to the author for his paper, which would do a good deal of good by stimulating public interest in the memorial. He very much

wished that some millionaires had been present, and had been roused by the address to put their hands in their pockets to make up the deficiency in the funds of the memorial to which the author had referred. Everybody wished that the scheme had been carried out in the way in which it was originally designed. It seemed a pity that, in a great and wealthy country like England, such a comparatively small sum should not be forthcoming. He would have liked to have seen the memorial erected directly by the nation, rather than by Parliament, *i.e.*, that every person who admired the late Queen should show their appreciation of her worth by contributing to her memorial. Had the question been taken up immediately after her death, he believed the money might have been secured. He hoped it was not too late even now to collect all the money which was necessary to carry out the original design. This meeting, he hoped, would stimulate the desire and the privilege of wealthy men to contribute to the scheme.

Mr. HARRY FURNISS said that before coming to the meeting he hardly thought the subject was a humorous one, but after hearing the admirable paper he felt there was some chance for men belonging to the class of low art to which he belonged, to make some money out of the Victoria Memorial, when it was completed. In his opinion the only good design shown by the author was that of the Irishman, he was the only man who seemed to understand the nation he was working for, because it struck him (the speaker) that in the end there would be buildings all round and nothing else. The paper might stimulate the British public to supply the funds for the completion of the design; but from what he could gather, if it did not do so, by degrees all the original design would disappear, and something which was outside it would be substituted. It rather reminded him of the old Irish story of the builders who were employed to preserve a church by putting a wall round it, whereupon they pulled down the church to supply the material with which to build the wall. He thought that would happen in the present case. He hardly liked to trust to his tongue any longer, because he rose with the intention of saying something flattering to the author, and nothing else. He would, therefore, only add that he was sure all present were deeply grateful to Mr. Spielmann for the admirable way in which he had brought the subject under the notice of the meeting, and for the delightful evening they had spent.

Mr. PERCIVAL HUGHES said, as one of the public he thought he might prophesy that the effect of the admirable paper they had just heard would be to stimulate the interest of the public in this great undertaking. If there was one thing required in London, and in which England was behind every other nation and capital, it was in the taste for architecture and sculpture. He thought England had quite enough public libraries, and if only some millionaire could be induced to turn his attention towards improving the sites of London, when opportunities were given for the erection of sculpture and architecture, he would be a public benefactor who would do some good for the public taste. He thought that most of the remarks which were made should be in the direction of congratulating the author upon the extremely admirable and interesting paper he had given. It had been not only interesting but educational; and he could not help feeling that the audience would be extremely grateful if more such papers were given to educate the public taste. It was the first time he had had the pleasure of coming to the Society of Arts, but he was sure it would not be the last; and he hoped that every evening would be as interesting as the one he had now spent.

The CHAIRMAN said it was natural that, as an architect, he should sympathise with and emphasise the remarks which had been made in regard to the alliance of architecture and sculpture. Sculpture in architecture was of great assistance in giving expression to, and giving an idea of, the purpose and object of the building; and architecture was equally important to sculpture, for it should be as a beautiful setting to the valuable jewel. The architect and sculptor should, he felt confident, work together from the very beginning. Mr. Brock had made that remark to him only a few days ago when they were discussing the matter; and almost all the monuments, if not all, which the author had shown upon the screen had been carried out by the architect and sculptor working together from the beginning. In the case of the Queen Victoria Memorial the sculptor was called in and commissioned to do the work, and had already made out his scheme before the competition for the architecture took place. It was so far fortunate that, in the present instance Sir Aston Webb was successful in winning the competition, because both Sir Aston and Mr. Brock were very much in sympathy with each other, and with their respective work, so that the result he hoped would turn out to be very satisfactory. He could imagine the remark being made, that although the piers had been erected, and certain balustrades had been put up, there was no appearance of the fine colonnade that was to surround the central group. It looked very much from the work as if that feature was to be omitted. He sincerely hoped that was not so, because it was a most important feature of the scheme, and would give great value to Mr. Brock's work. It would give scale to it, because they could not always expect to have the little figures fixed down by the side of the group to show the scale, so that there would be really nothing there besides the big piers, which would be valueless for that purpose, and the palace in the rear; whereas if the colonnade was carried out, one would be able to judge something of the size and importance of Mr.

Brock's beautiful design. Not only would it give the work scale, but it was a shrine which was necessary, and would form, as he had already said, a beautiful setting for the jewel which was put in the centre. The screen also would not hide the beauties of the park, because on the ground level it would only be framed by the columns, and he also believed there would be no obstruction from the Palace; the view would still be the same. The importance of the colonnade was that it gave value to Mr. Brock's work, and made it a fitting tribute to Her late Majesty. If the group was left alone out in the open it did not appear to him to be quite respectful. He looked upon the colonnade as a sort of architectural batallion in attendance on the great Queen, and he thought it would be a great calamity if it was not built. If funds were wanted to carry out such a feature, there should be no difficulty in obtaining them, and if an appeal was made at once he was sure sufficient funds would be forthcoming to supply what, in his opinion as an architect, was a most important feature of the whole work. On behalf of the audience he wished to express to Mr. Spielmann their thanks for the admirable and interesting paper that he had read.

The resolution having been carried unanimously,

Mr. SPIELMANN, in reply, said he was very grateful to the President of the Royal Institute of British Architects, and also to the other gentlemen who had spoken so kindly about his paper. He regretted that there had not been very much in the form of criticism to which one could reply. He thought it was quite hopeless at the present time to consider that the colonnade would be carried out. He was not sure that the question of money, which of course was a very serious one, was the only objection; it was quite possible that in the future the plan might be continued; at any rate, that it would not be relegated absolutely to one side. The collaboration of an architect and a sculptor was, as had been mentioned, practically unknown in this country, but a start had been made, with very happy results, in the Queen Victoria Memorial which had lately been put up at Bradford, where Mr. Drury as the sculptor, and Mr. Simpson as the architect, worked together from the beginning, and had produced an extremely original work, which had the great merit of being entirely cohesive and harmonious. He was extremely obliged to all present for the very cordial reception they had given to his paper.

Mr. PHILIP NEWMAN writes:—I should like to add a few words to the chorus of approval of Mr. Spielmann's paper, and to refer to Sir Charles Lawes Wittewronge's dictum on the relative scale of sculpture and architecture. While all must agree that great disproportion between the figures themselves in the same monument is (as was fully illustrated) an artistic mistake, Sir Charles's contention that sculpture is often so large as to dwarf its architectural setting or surrounding should scarcely pass unchallenged. The question raised is an academical one, not only reflecting on the present subject and scheme, but on a canon of Greek taste as evidenced in too many instances to enumerate.

THIRTEENTH ORDINARY MEETING.

Wednesday, March 8, 1905; the Right Hon. LORD REDESDALE, K.C.V.O., C.B., in the chair.

The following candidates were proposed for election as members of the Society:—

Adams, John Henry Maudslay, Broughton Cottage, St. James's-road, Waverley, Sydney, New South Wales, Australia.

Davis, Joseph Edward, 24, Maple-road, St. Thomas, Exeter.

Dewhurst, Wynford, Chelmscote, Leighton Buzzard.

Griffith, Samuel Barnes, 8, John-street, Adelphi, W.C.

Holding, Edwin, Balmain, New South Wales, Australia.

Kilburn, Bertram Edward Dunbar, M.A., Assoc.M. Inst.C.E., 6, Stanhope-street, Hyde-park, W.

Lawson, Eric St. John, Bangkok, Siam.

Medley, Charles Powis, A.M.I.Mech.E., 103, Worship-street, E.C.

Mocatta, Elkan B., 31, Great Cumberland-place, W.

Munton, Frederick Thomas, F.C.S., Beaconfield, Weston-road, Runcorn.

Newcombe, Robert William, 9, Groveland-avenue, Hoylake, Cheshire.

Ross, James William George, 143, Mitcham-lane, Streatham, S.W.

Tepowa, Adebiyi, Customs House, Calabar, West Africa.

The following candidates were ballotted for and duly elected members of the Society.—

Bacon, John Henry Frederick, A.R.A., 33, St. John's Wood-road, N.W.

Dickson-Brown, S., M.A., 31, Regent-square, W.C.

Earnshaw, Henry, 14, St. Mary-axe, E.C.

Evans, William Bailey, 20, West-parade, Huddersfield.

Fergie, George, Copiapó, Chili, South America.

Lello, Montague Nodes, 100, Belsize-road, South Hampstead, N.W.

Little, Robert, Singapore, Straits Settlements.

Minett, Richard, F.S.A.A., Municipal Offices, Cheltenham, and Cedar-lodge, Cheltenham.

Rolfe, William, 3, Adelaide-street, Charing-cross, W.C.

Steuart, James, 205, Clay-street, Baltimore, Maryland, U.S.A.

Tosh, William, J.P., M.I.Mech.E., P.O. Box 1132, Johannesburg, Transvaal, South Africa.
Williams, D. Neziah, 29 Tudor-terrace, Merthyr Tydfil, Glamorganshire

The CHAIRMAN, in opening the meeting, assured the audience that he was using no idle words when he said that he felt it a very great honour to have been asked to preside over a meeting at which a paper was to be read by His Excellency, Baron Suyematsu, an ex minister of the Interior in Japan, and a man connected with all that was best and noblest in his native country. He knew well that the first duty of a Chairman was to efface himself; he should be like the man who beat the drum and clashed the cymbals outside a show at a fair inviting the public to come in and see the giant; and he therefore would only assure the author that he would receive a most cordial and sympathetic welcome from the audience.

The paper read was—

THE ETHICS OF JAPAN.

By BARON KENCHO SUYEMATSU, B.A., LL.M.

I have been asked by your Council to read before you a paper on the ethics of Japan, and this is my attempt in response to that request, though very imperfect it must necessarily be.

There are three sources of factors which influenced the moulding of the ethical system in Japan, namely Shintoism, Buddhism and Confucianism. The first is the native religion of Japan; the second is, needless to say, a religion originated in India and introduced to Japan through China and Korea; and the third is the moral teaching of China. As to the relative positions of these three, I have already fully explained this in an article entitled "The Religions of Japan," in the December number of the *Independent Review*. They are not antagonistic to one another, as people not living in Japan might imagine, and as would only appear natural to them from their own notions of religion. Of these three, Buddhism is the most religion-like in the ordinary sense of the term. Shintoism ranks next, but it is very simple and liberal if viewed in the light of a religion. Confucianism comes last; it is ordinarily classed by Western writers as a religion, but as a matter of fact its religious aspect is very vague, and it is not considered a religion by the Orientals. Perhaps a better term for it would be the Chinese teaching of morality, because moral notions which can be gathered from Chinese study are comprised in all sorts of Chinese writings, and Confucius, the great sage, is only one of the exponents thereof. Confucius, however, takes a very high place among those exponents, and therefore he came to be revered more than any others by Orientals, and thus Chinese teaching came to be usually associated with the name of that great sage. I cannot do better than follow this example and call Chinese teaching by the name of Confucianism.

Comparing these three systems of teachings with regard to ethics, Confucianism stands out very prominently in its systematic exposition and practical utility. Buddhism it is said is very philosophical, and deep in its ideas of the cosmos, and there is no doubt that it is capable of exercising a great influence on the popular notion of a future life, though it does not do so as much in Japan as in some parts of the Asiatic continent. It has, however, very little to say with regard to ethics relative to the actual life of the human being. It says you must not do wrong—it says you must do good —but as to what is good or what is bad it is very vague in its meaning. It suggests rather religious notions than practical ethics, how one should behave in this world towards one's fellow creatures or towards the community or State to which one belongs. It speaks of ten warnings and four benevolences. The ten warnings are:—1. Do not kill the living. 2. Do not steal. 3. Do not commit adultery. 4. Do not speak wantonly. 5. Do not make sensational exaggerations. 6. Do not calumniate. 7. Do not use a double tongue. 8. Do not be greedy. 9. Do not be angry. 10. Do not entertain crooked views.

The four benevolences which one has to remember are:—1. The father and the mother. 2. The ruler of the land. 3. "All beings." 4. The three treasures, *i.e.*, the Buddha, the Laws, and the Priesthood (Order).

It speaks of compassion and forbearance. It also speaks of eight correct ways:—1. Correct views. 2. Correct thoughts. 3. Correct words. 4. Correct conduct. 5. Correct living. 6. Correct ministration, meaning self-reflection and aspirations. 7. Correct conception. 8. Correct mediation. In their essence, however, all these teachings are mostly of negative character, and, moreover, I must say that they have more importance from a religious point of view than from an ordinary, and a practical ethical point of view. Therefore I can say that Buddhism has very little to do with the ethics of Japan in the sense of a systematic exposition of them, though in an indirect way it has had some influence on

the moral atmosphere of the Japanese, as I shall show later on.

The Chinese teaching, otherwise called Confucianism, is a system of moral teaching founded upon a patriarchal system of community. It does not, therefore, only speak of the good conduct of an individual, as relating to his fellowship with other individuals; but also from the point of view of the whole system of community as a state. Therefore it speaks of modes of governing and of being governed, as well as of individual relationship between man and man. It does not recognise any difference between sovereignty and ruler, nor does it notice a difference between State and country. In it, the greatest natural bonds of humanity are five, and they are:—1. Sovereign and subjects. 2. Father (implying also mother) and child. 3. Husband and wife. 4. Brothers (implying also sisters). 6. Friends. To each of these relationships, the essential duty which is to be borne in mind by each individual is separately attributed, and to each of these duties a special term is given to designate its actions from the point of view of a virtuous nature. Besides these five relationships there are two other relationships which have to be added, namely, the relationship between the elder and the younger, not necessarily meaning brothers, and also the relationship between master and pupil. The term, "the sovereign and subjects," in Oriental notions, signifies in their bearing a very deep meaning in their mutual relationship. I once heard from a very trustworthy authority that a Western diplomatist, well versed in Oriental affairs, had said that the Oriental idea concerning sovereign and subjects was not, and could not, be thoroughly understood by Occidentals, and I think that remark is not far from the truth.

The idea of the best virtue that a sovereign can have is "jen," meaning to be as humane as possible to his subjects, detesting oppression, giving the best administration to his country—in a word, to be the best ruler that ever ruled a land. The idea of the best subject is loyalty. The idea of that of father and son is filial piety on the part of the child, and strictness on the part of the father, which is modified in the case of the mother towards tenderness, for which there is a special term. The idea which governs the relationship between man and wife is harmony. The older word for this was "distinction," meaning "not to be unseemly," but the word "harmony" is also used sometimes, and we Japanese prefer it. The idea of that of brothers and sisters is brotherly friendship, for which also a special word exists. The idea of that of friends is trustworthiness. In this way all the five cardinal bonds are dictated by desirable manifestations of sympathetic attentions to one another. But of course more prominence is given to the virtue of a subject, a child, or younger brother, in the case of a sovereign and subjects, of parents and children, and of brothers respectively. Then, again, the elder and the younger in general are expected to respect each other as the case demands, and the relationship between them is to be regulated by a term which is equivalent to the English word "order," that is to say, the younger should not seek to supersede the elder, but to pay respect to him, whilst the elder is expected not to take advantage of the younger but to treat him with kindness. The relationship between master and pupil is also regarded as very important. The pupils are expected to respect their master almost as much as their parents, whilst the master is expected to treat his pupils with parental kindness; no businesslike thought is to enter their minds. In the olden times in the East the system of teaching and learning was very different to that which exists in these modern days. The teacher taught his pupils out of the love of imparting his knowledge and virtuous example, as well as the doctrinal principles he entertained, whilst the pupils were supposed to gather around him out of their admiration for the personality of their master and for the purpose of receiving his instructions and influence for their personal improvement and future usefulness. Such being the case, it was no wonder that the relationship between a master and his pupil was regarded with so much importance in ethics.

Apart from these classifications the virtuous attributes of man are spoken of in several other ways. We have first of all "wisdom, humanity, and courage." These three are considered to be the three greatest traits of character to be embodied in one person. Wisdom may not exactly fall under the category of a virtue in its strictest sense, but I suppose we need not be very critical on this point. In this instance humanity, that is "jen" in the Chinese original, may be interpreted as comprising every other virtue besides mere mercifulness. There is another catalogue, viz.: "humanity, justice, decorum, wisdom, and faithfulness." These five are considered essential elements of virtue for regulating a community, and should be

observed by each member of it. There is another—"filial piety, brotherly friendship, loyalty, and faithfulness;" these give guidance to a man in his capacity of a son, a brother, a subject, and a friend. There is yet another—"sympatheticability, goodness, respectfulness, self-restraint, and modesty." These are virtues considered important as regards one's self-control. As to the women, "quietness, modesty, and purity" are considered the ideal traits of their character, besides all those which I have just described above, which are of course applicable to women to an extent almost equal to men.

In the West the term love plays an extensive part in governing all the mutual relationships of the kinds enumerated above. The essence of Oriental ideas does not differ from it in its purport, but expressed in words the word love does not play so extensive and imperative a part as it does in the West, because in the Confucian doctrine different technical terms are used, as we have already seen, to meet each particular case. The word love is used very sparingly in the Confucian books, and it is used more especially for designating one kind of virtue as, for example, "extensive love" meaning philanthropy in the Western sense. The word "jen," which ordinarily may be translated as humanity, more resembles the Western word love, because that word "jen" may be interpreted in many ways suitable to the occasion on which it is used, almost in the same way, and in a similar sense, that the word love can be used. But the meaning of that word "jen" is more comprehensive and deeper because it implies some other meaning than mere attachment. I will not worry you by going into full details of the interpretation of that word, as it is too technical. There is, however, one thing worth noticing about the word love in Chinese. When that word is singled out it is also applicable to many cases, including the relationship above enumerated. Thus it can be used in a very comprehensive manner, and thence there arises a question about the essence of the word. The question is whether the notion of love is absolute, and consequently has no gradation or differentiation in its nature. At the time of Mencius, sometime after Confucius, there was a school of philosophers who maintained that there ought not be any differentiation, but Mencius maintained that that was a fallacy. The word may be the same, but the practice may be differentiated according to the circumstances. The meaning is that one should love a nearer object more than a distant one, and thus the ethical notion of cosmopolitanism was reconciled with other notions of different virtues—in other words, if one does good to his neighbour more than to a stranger, or if one does more good to his country than to other lands, out of the feeling of love, it is quite justifiable from an ethical point of view, and thus Chinese ethics are made reconcilable with the principles of state. And this is, I think, an important landmark in which Confucianism differs from the features of an ordinary religion, which in its essence is, as a rule, founded upon cosmopolitanism, and knows not an artificial boundary of states.

There is a Chinese maxim which says, "No loyal subject serves two masters, and no virtuous woman sees two men." The cardinal points of the Chinese ethics are loyalty and filial piety; so that, although all sorts of virtues are inculcated, greater importance is placed on these two points. In China, learning means studying moral teaching. There are, of course, many subjects for study, but moral notions pervade every branch of literature. It is so, even with history. Chinese histories, as a rule, record only events as they occur; they have no historical or political observations, and any observations made by the writers are written in such a way as to draw attention from a moral standpoint. Their histories, therefore, have very little value in the ordinary sense of history, as the term is employed among Western nations, but the fact remains that they pay much attention to moral lessons. Their expositions of moral teaching are done more in the way of philosophical or scholastic dissertations. The ethics of China, however, were not necessarily identical throughout the long period of her history, extending over several tens of centuries. There were several schools of philosophers besides Confucius, some of whom even went so far as to differ from him in many points; and also the interpretations of Confucianism differed at different epochs. But the chief feature of his teaching has always remained the same, and all that I have said about it above represents fairly the idea of Confucian doctrine. It is natural that Confucianism should be regarded as a sort of religion, because its followers respect it almost as a believer in religion respects his creed; moreover, Confucianism recognises in a measure the existence of some supreme power. It speaks of heaven in the sense of a power; it speaks of the "order of heaven;" it even

speaks of the "supreme emperor," meaning the supreme being. It also recognises the immortality of the soul, though in a vague manner, and pays great attention to festivals given in honour of one's ancestors; to use a common phrase, it worships the ancestors. But the parts of Confucianism which relate to the future of man only form a subordinate element of it, so much so that Confucius himself once said, "I do not yet know the living, how can I know the dead?" At all events I, in common with most Orientals, do not regard Confucianism as a religion in its ordinary sense. There are of course many customs and matters of etiquette sanctioned by Confucianism, or rather enforced by it, which are absurd or impracticable in the eyes of the Japanese, but there is no necessity for me to dwell upon these shortcomings here.

Let us now see what is Shintoism. It is essentially indigenous to the soil of Japan. It may be regarded as religion, and yet if it be a religion it is certainly of a unique kind, having nevertheless much similarity to the ancient cults of the Greeks and the Romans. It has no founder, nor has it any dogmas, in the ordinary sense of a religion. It has grown up with the customs and traditions and general characteristics of the nation. It recognises the immortality of the soul; it acknowledges the existence of supernatural powers; it reverences the ancestral spirits, and therefore it may be called a religion of ancestral worship. In that respect it resembles Confucianism. It concerns itself, however, with temporal affairs far more than with spiritual affairs. In this respect also it very largely resembles Confucianism. It has existed in Japan from time immemorial, long before the introduction of Confucianism and Buddhism.

From an ethical point of view it has more teaching in it than Buddhism, but it is not so elaborate as Confucianism. Nevertheless, it has a tight grasp of the Japanese mind. It is supremely content with its simple tenets, so much so that a well-known scholar, who was a devout supporter of it, when speaking of its ethical teaching in comparison with Confucianism, once said that "We do not want so many nomenclatures as Confucianism requires to signify all sorts of virtues and good conduct, and our simple teaching is quite enough to cover all."

Shintoism is also based upon a patriarchal form of community. Its essential notion of ethics is cleanliness of conscience; but the idea of cleanliness is applied not only mentally but also physically—hence its tendency to bodily cleanliness as well as other cognate matters. It speaks of good and bad; it designates bad minds as "black" or "muddy," and good minds as "red" or "clear." Its ideals of conduct are honesty and straightforwardness. It reverences its ruler from the very nature of its cult, and a magnificent ideal of a subject and a citizen is developed from these simple notions.

Such are then the three great sources of Japanese ethics. It is like the foam produced by currents of water. The water is the source, but when foam is produced it differs from actual water. So Japanese ethics are produced by the intermingled notions of these agencies, but they are no longer of the same substance as their source. I mean to say that our ethics have formed their shape quite independently of the orthodox or dogmatic parts of any religion, and people regard them as such in the same way as one would ordinarily regard foam as differing from water. I will now explain how this has been brought about. From about the sixth century of the Christian era Chinese study was introduced into Japan, and almost simultaneously Buddhism was also introduced to our country. The study of Chinese, as I said before, means the study of Chinese ethics, and I may say that Chinese has become almost like our own literature, though we had our vernacular literature coexisting. The study of Chinese, therefore, meant the introduction of Chinese ethical notions, in the same way as the study of Greek or Latin introduced Greek or Roman notions into European countries. This, however, did not mean that it supplanted our own ideas of morality, but it rather supplemented and augmented our notions in so far as it concerned the nomenclature and classification of different ethical virtues. We did not mean to make ourselves slaves to Chinese notions, we rather utilised Confucianism; and therefore Confucianism, as interpreted in Japan, is not the same as Confucianism in China. There is a story told of a Japanese professor, who was a deeply-read Chinese scholar, and his pupils. The master once asked his pupils, "Suppose China invaded Japan with an army led by Confucius himself as the generalissimo, and assisted by Mencius as his lieutenant; what would you do?" The pupils replied, "It would be our bounden duty to take up arms unhesitatingly for our country and beat and crush them to pieces." Thereupon the master smiled and expressed

his glad assent. This will show how we interpret Chinese teaching. Then also Buddhism, poor as it is in ethics, has contributed something towards forming our national character, in that it has indirectly assisted in inculcating gentleness, and also kindliness to living beings. I may go a step further: Buddhism itself as interpreted in Japan is not the same Buddhism as it was originally. It had to accommodate itself to the requirements of the country. Then also Buddhism in China and Japan is studied in books which are translated into Chinese, and therefore the priests who study their own religion have also to study Chinese, which, I repeat, involves the study of Confucianism, and therefore they are familiar with that teaching. The Japanese priests, therefore, made use of Shintoism and Confucianism in their own teaching on any points where they found their own teaching was deficient, that is to say they did so in practical and moral teaching. And, not only that, we notice even the dictum of Buddhism itself is sometimes modified to suit such purposes. I mentioned above four benevolences spoken of in Buddhism as being "the father and the mother," "the ruler of the land," "all beings," and "the three treasures." I do not know whether this is to be found in the Sanscrit original, I think it is not, it sounds more like a Chinese Buddhistic notion. It is still further modified in an old Japanese book as "heaven and earth," "the ruler of the land," "the father and the mother," and "all beings." And thus for "the three treasures" is substituted "heaven and earth." This occurs in a passage which is put into the mouth of a famous Shigemori in a discourse which he made when he severely admonished his father Taira-no Kiyomori, though with filial tenderness, when the latter had behaved badly towards his sovereign the Emperor. The passage is to be found in a famous book written in the middle of the fourteenth century by Kitabatake Chikafusa, who was a court noble, a royalist, and a man with much knowledge of Buddhism.

Here I have to speak of Bushido. The term, as well as its general purport, has been of late made widely known in this country; but, as many people wish it, I will say something about it, although it may be only, as we say, "adding legs to the picture of a serpent," I mean it may be quite an unnecessary addition. Bushi literally means a military gentleman, or in more common English, a military man; and "do" literally means a road or way, and in its extended significance, a principle, a teaching, or a doctrine. The term for "Bushi" in old refined Japanese is "Mononofu," and the term for "do" is "Michi," therefore the more refined ancient Japanese name for Bushido was Mononofu-no-Michi. The origin of the "Bushi" is as follows:—They were originally large or small landlords of the provincial parts of Japan, and had their retainers or vassals. At the time when, in the court of the empire, over-refinement, or rather effeminacy, succeeded enlightenment, and nobles who usually resided in the capital came to despise military service, those landlords and their retainers began to play military *rôles* under different distinguished leaders. They were more prominent in the eastern parts of the country, called Kwanto, namely, the large plain, in the middle of which modern Tokio is situated. With the march of events, when the governing power fell into the hands of the military leaders, these landlords and their retainers began to form an hereditary class, and the system extended to the whole country; this is the origin of Daimio and Samurai. I do not say that in the case of later developments of this system all Daimio and Samurai necessarily belonged to the same ancient stock, because at the time when the country went through many stages of war many new men appeared on the scene and enlisted themselves in the ranks of the Samurai, among them the Bushi, several of whom became Daimios themselves by their personal valour and the distinction they attained. But I may say that on the whole the successive stages of the class always inherited and handed down the same sort of sentiments and notions as their predecessors. We may in a measure compare this military class with the country squires in this country, who gradually became barons of the middle ages, together with their children and retainers. "Bushido" is no other than the doctrine held and cherished by that class as its code of honour and rule of discipline. In the earliest days of the development of that class, individuals forming it were not cultured or enlightened in the sense of luxurious refinement; in other words, they were mostly illiterate. But on the other hand they were mostly men with healthy notions of manliness in contrast to those who usually lived in the capital town where literary and artistic culture under Chinese influence had been attained in a marked degree. The motive and sense of their culture were therefore more like those belonging to primitive

Japan, unstained by foreign influences. The families belonging to this class were called in their early days "the houses of the bow and arrow." Needless to say that the early projectile weapons of warfare were the bow and arrow, and they had a place of honour amongst the warlike instruments of those days. Little by little a phrase "yumi-ya-no-michi," literally meaning "the ways of the bow and arrow," came into existence, and it was the original name of Bushido. At first, perhaps, the word referred more especially to the proper use of the instrument of war, but it soon came to signify something more. There were many ceremonies and etiquettes which grew up with a warrior's life and military affairs, not only with reference to his comrades or to his superiors and inferiors, but also with reference as to how he should comport himself towards his enemy. At the bottom of all these matters there lay the idea of honour, not merely one's own honour, but also a compassionate regard for the honour of the enemy. All these ideas came to be implied in the term "the ways of the bow and arrow." Here we see that special moral sentiments were being awakened among this class. Bushido, however, has no particular dogma or canon, except such as grew from practice, and except those of which we can gather some idea from instructions given by certain leaders or by certain teachers of military ceremonies or science in the way of interpretation of such matters. Here we have an instruction given to his men by Yoritomo, the first Shogun, and therefore one of the early leaders of the system. The essential points of the instructions are these:—1. Practise and mature military arts. 2. Be not guilty of any base or rude conduct. 3. Be not cowardly or effeminate in behaviour. 4. Be simple and frugal. 5. The master and servants should mutually respect their indebtedness. 6. Keep a promise. 7. Share a common fate by mutual bondage in defiance of death or life.

We may say that notions such as these were the foundations of the ethical parts of Bushido. These will mean when interpreted in ethical terms of the Chinese school:—1. Diligence in one's profession. 2. Love and loyalty between master and servants. 3. Decorum and propriety. 4. Gallantry and bravery. 5. Trustfulness and justice. 6. Simplicity and frugality. 7. Contempt of meanness.

At the bottom of these lay the sense of honour. When speaking of any action as unworthy of a Bushi, the following phrase was customarily used in early days, "It is disgraceful in the presence of the hand of the bow and arrow," as in later days one would say "a disgrace to Bushi," in the same way as you would say in English, "it is unbecoming to a gentleman." The term "Bushi" has in many ways a similar meaning to "gentleman" in English. Bushido, of course, encouraged bravery above all things. In an old book describing the war between Gen and Hei, an account of the bravery of Bushi of Kwanto—namely, the plain above referred to as that where Bushido originated—is put into the mouth of a general of Hei as having been addressed to his generalissimo, who commanded the army of Hei, which was formed of recruits coming from Kioto and its neighbourhood. The narrative was to this effect:—"According to the usage of the warriors of the East, the son would not withdraw from the battlefield though his father might die, or the father would not think of retiring though his son might fall. He would advance and advance, and jumping over the dead, would fight regardless of death or life. As to our own men, they are all weakly recruits from the neighbourhood of the capital [where effeminacy reigned at the time]. If the father were wounded, the son and all the members of the family would take advantage of this and retire; if the master were killed, his followers would utilise the chance, and, hand in hand with their brothers, would withdraw and disappear." This may be a somewhat exaggerated account, but it will show how greatly the original Bushi estimated bravery, in the same way as our men do in these days.

In addition to these characteristics, some other features which were brought into more prominence are entitled to be singled out, namely, fortitude, generosity, imperturbability in the presence of danger or on any unexpected occurrence, compassionateness, and straightforwardness. This kind of attitude was inculcated even in physical exercises of different modes of fighting, such as fencing, practice with the spear, and jujitsu. There is a verse composed by a Japanese which may be translated thus:—

> Even in the eyes of the warrior
> Whose beard is ten fists long,
> The one thing that softly flows from them
> Is the tear which is due to love.

This aptly expresses the innate tenderness of heart of a Japanese warrior. There is another verse composed and penned by Commander Takeo Hirose in Chinese just before

he went to his doom on the occasion of the second bottling up of Port Arthur, and which, therefore, constituted his last utterance in this world; translated into English it runs as follows:—

> "Would that I could be born seven times
> And sacrifice my life for my country:
> Resolved to die, my mind is firm,
> And again expecting to win success,
> Smiling I go on board."

This will show the fortitude and determination of a Bushi at the hour of his exit from this life, and though Hirose was a man of our own day, he may be regarded as one of the best types of an old Bushi.

Bushi is not foreign to Shintoism; as a matter of fact, Bushi generally respect Shinto deities, and, moreover, some military ceremonies were performed in the supposed presence of a Shinto god. Bushi openly invoke the god of war without any compunction, but Bushi never have done so in a bigoted way. It was more in the way of reverence paid to a deity of their inherited cult. They were never devotees of Shintoism as a religion. This sort of sentiment of the Japanese is very difficult to explain with clearness, but my meaning is that though they do not despise religion they place more importance on the affairs of the world and on their own exertions in the matters which they undertake. The Samurai do not worship their deity in order that their souls may be safely rescued in the future. I can therefore say that Bushido, as such, has no bearing upon Shintoism. It has its own independent existence, although to the extent I have just referred to it has its connection with Shintoism. In other words Shintoism was a cult founded upon our old customs and traditions, and therefore Bushi also shared the sentiments pervading that cult, but we cannot say that Shinto has produced Bushido.

And again, Bushi do not despise Buddhism, on the contrary many of them may revere it, but Bushido, as such, has no connection with this faith. In documents they often make use of a phrase in a vague way, "by the help of Shin-Butsu," meaning both the Shinto deity and Buddha; but it does not mean that it has any foundation in Buddhism. If a Bushi were a believer in Buddha he probably would not like to show it. We have a story about Yoritomo, the first head of the Shogunate. When he first started in his youth his campaign against Hei, and hid himself in a mountain nook, having been defeated by his enemy he took out from his queue a small image of Kwanin (Kwannon) which he reverenced, saying, "if my head be taken by the enemy it would not be becoming to the generalissimo of Gen if this image were to be discovered." This will give you an idea of the way in which Buddha was viewed by Bushi. As we all know, Buddhism chiefly speaks of the future world. The idea of the Bushi was that it was an act of cowardice if one merely did good because one wished to be saved in the future world. Their idea was that good should be done for its own sake, and therefore if one believed in Buddha he had a sort of apprehension that he might be considered a coward. Of course history is not wanting in many instances of great warriors believing in Buddhism, but in many cases this fact had no great significance as far as their conduct and conscience were concerned. There was, however, one feature in which a certain aspect of Buddhism had a considerable influence in moulding Bushido; it was the influence of the teaching of the Zen sect. This requires some explanation. In the thesis of Buddhistic teaching there is included the idea of absorbing everything in the universe into oneself, in other words mental annihilation of all things except oneself. This is done by long and fixed meditation, and at least so far as he himself is concerned, a man can for the moment imagine and realise mentally that he is the only being in the universe, and all other things become nothing. Hence, when he is accustomed to meditation of that description, nothing will ever surprise or frighten him. There is a story about Hieuntsang, the famous Chinese Buddhist of the Tan period, who visited India. This priest was once caught by a band of robbers. He sat quietly down and began to meditate in the way described above. The robbers tried to intimidate him by threatening him with drawn swords pushed right into his face; but the priest took no notice whatever of what they were doing to him, and remained entirely unmoved. The robbers, observing the attitude of the priest, and thinking that he must be an extraordinary personage, all went away and left him alone. This phase of Buddhism was introduced into China, where it became the cult of one separate sect of Buddhism. Bodhi-Dharma, an Indian priest, who visited China, is commonly accepted as the founder of this sect, which practices meditation more than do other sects, but of course meditation is not its only feature. In general we may say

it is more philosophical in the sense of regarding the universe in a nihilistic sense. This sect is called Zen, and it has been introduced into Japan also. It was patronised by several eminent Bushi in its earlier stages. Perhaps it was liked by them in that according to its doctrine, a man puts aside the idea of reliance upon another, and places himself above every thing else, and it was found to have an agreeable resemblance to the spirit of self-reliance inculcated by Bushido. In the second place it repels all ideas of luxury and display and values simplicity and cleanliness, and in that respect it was found to bear an agreeable resemblance to the frugal and simple life of the Bushi. Thus the Zen came to exercise its influence over the Bushi, but not at all in the sense of believing in future felicity; quite to the contrary, from the very nature of that sect. This influence of Zen seems to have helped to a great extent the development of some of the characteristics of Bushido, such as imperturbability, stoicism, fortitude, and simplicity and cleanliness of thought or body. Here I may add that many traits of Bushido are no doubt to be found in the European knighthoods of former days, and therefore they are not really new to the Europeans who still remember those traditions.

The weakest point of Bushido in its earlier stages was its want of literary culture in the way of systematic ethical study, hence it easily happened that a thing one might regard as correct might not be correct in reality when examined from a higher point of view. This difficulty was especially observable when two obligations came into conflict, and one had to be preferred to the other. The Bushi, in the earlier stages, knew more about their duty to their immediate master than to higher ones; hence their difficulty in discerning their duty to the supreme ruler of the land and their immediate head. Of course, they knew that the Emperor was the highest personage in the country, but they were unable to find out an ethical solution of the question, and indeed in all matters they wanted more systematic enlightenment.

These wants, however, have been supplied gradually as time went on, especially during the last three centuries. During this period almost unbroken peace reigned in the country. It ceased to have any intercourse with foreign countries except in a limited sense, but internally all branches of art and industry were encouraged and developed side by side. The study of Chinese and of native classics have been carried out in all parts of the land, and it was the Bushi who chiefly devoted themselves to such culture. Bushi or Samurai were retainers, as everyone knows, of their lords, and certain pensions were given by their lords to each family, according to their rank, so that they had not to work for their own living. Hence their only duty was to make themselves physically and mentally fit to fight for their lords in time of necessity, and, in times of peace, to make themselves as much like gentlemen as possible. In other words physical training and mental enlightenment, together with the refinement of their manners and habits, were their sole business—they had no other occupation. For, indeed, any other occupation which partook of the shape of business conducted for profit was forbidden, and was despised among them. Bushido came to be deeply imbued with the principles of Chinese and Japanese classics as they were taught. I have shown above that in the systematic exposition of ethical ideas, Confucianism was the richest of all, and the essential part of it was taken by Bushido; as I have also shown above, there are many defects in the Chinese teaching; all the unimportant parts were cast away and the important parts were taken into the teaching of Bushido, and even these parts only in such a way as to suit our national traditions and characteristics, the essential spirit of Shintoism also being resuscitated in such a way as to give an impetus to Bushido, though in no orthodox manner. Such then is our Bushido. The Bushi formed the governing class of the Japanese society, and it may be said the educated class also, or in other words the Bushi may be called the gentry of the country. We can, therefore, say that Bushido was the ethics of Japanese society. In one way it may be said that Bushido, as such, was a monopoly of the military class, but in truth its spirit was not confined to this only; the literary study of Chinese, as well as of native classics, was not necessarily limited to the military class; hence the same notions which were imbued in it through these studies were also quietly extending their influence among people at large—amongst whom, I may add, there were many families of old Bushi, or families which were quite equal in their standing to the Bushi class. Moreover, the spirit of Bushido has also been making its influence felt by other people. Thus we can see that the nation has been preparing itself for centuries for the pro-

motion of moral ideas of the same kind as those of Bushido.

The cardinal points of Oriental ethics, as may be expected, are loyalty and filial piety. In China, filial piety takes precedence, but in Japan loyalty stands first. There is a poem by Sanetomo, the third Shogun of Kamakura and second son of the first Shogun, which may be translated literally as follows:—

"The sea may dry up,
The mountain may burst asunder,
But no duplicity of thought
Shall I have to my Sovereign."

Such is the idea of loyalty which has been taught to the Japanese for centuries. Side by side with loyalty the idea of patriotism—a term which in Japanese is almost identical in its purport with loyalty—was also inculcated, though the development of this last idea was later than the former. Then also all the other ideas relating to ethics, especially on the lines indicated in Confucianism, were inculcated side by side. With the abolition of the feudal system, some thirty years ago, the structure of Japanese society was totally changed, or rather restored to the condition which preceded the ascendency of the military class in the twelfth century. The question now arises, what is the actual state of ethics in Japan at present? There is a new element which has been introduced into Japan in recent years, and it is in the form of Christianity. The constitution guarantees freedom of conscience, and therefore there is no hindrance to the propagation of the Christian doctrine with its moral teaching, and, as a matter of fact, there are a number of Japanese who have embraced that faith, but they are after all a very small minority compared with the number of the whole Japanese population. The essence of Japanese ethics is the same as existed prior to the new epoch, with certain modifications actuated by the new force of the altered conditions which, after all, are only in small details. I may say, in a word, that the Japanese ideal ethics form an extension of Bushido among the people at large from the non-extinct class of Bushi with whom it originated. As to how they stand at present, and how they are inculcated among the people at the present time, I must refer my audience to an article entitled "Moral Teaching of Japan," which was contributed by me to the February number of *The Nineteenth Century and After*. The sphere of the teaching is extensive, as is necessary from the very nature of the matter, but its essence may be summed up in a comparatively small compass. For this I cannot do better than quote a part of the so-called "Imperial Educational Rescript" given to his people by the present Emperor. It is quoted in my article to which I have just referred, but I will recite it once more:—

"It is our desire that you, our subjects, be filial to your parents and well-disposed to your brothers and sisters. Let husband and wife dwell harmoniously together; let friends be mutually trustworthy. Impose upon yourselves self-restraint and rectitude of behaviour. Extend to the multitude philanthropy. Advance learning and regulate your pursuits, developing the intellectual faculties and perfecting the virtuous and useful elements. Further, seek to enhance the public good and enlighten the world by deeds of social benefit. Treasure always the fundamental constitution and respect the national laws. In any emergency exert yourselves in the public service, and exhibit voluntarily your bravery in the cause of order. And by every means assist and promote the prosperity of the Imperial *régime*, which is lasting as the heavens and the earth. Thus you will not only be our loyal subjects and good citizens, but will manifest the highest and best traditions of your ancestors."

Such then are the essential phases of the ethics of Japan. They may be far from reaching your lofty ideals and expectations, but we are contented with their general tendency, while at the same time we do not forget to inculcate the necessary furtherance and expansion of our ideas required by the changing circumstances of the time. We are likewise mindful of the desirability of carrying them out in such a way as not to conflict with the best ideals of any other country, for our sole aspiration is to preserve harmonious relations with the whole of mankind.

DISCUSSION.

The CHAIRMAN, in proposing a cordial vote of thanks to the author for his very able and interesting paper, said he was sorry to say that a great many years, more than he cared to recollect, had passed since he first became acquainted with Baron Suyematsu's noble country. In those days very little was known about Japan. People knew that somewhere in the Far East there was a country which produced lovely works of art, and which they were told was unrivalled for its scenery. They knew it was called the land of the Rising Sun; now he thought they could call it the land of the Sun that had risen. If people in those days knew very little about Japan, on

the other hand Japan knew still less about the West. Japanese gentlemen did not travel as they did nowadays; they remained at home; and he believed there was actually a law which prescribed that any Japanese who left his own country and travelled in foreign countries should, for that very reason, be executed when he returned home. All that had changed. They now stood lost in admiration before a country which had proved itself to be one of the greatest nations of the world, although it was so short a time since it first entered the community of nations. The paper had been one of great interest to him personally, because it had described many of the elements which had gone to form the Japanese character, a character which Englishmen had learned to-day to look upon as the very essence of all that was noble and chivalrous. Baron Suyematsu had said a good deal about the Bushido, which meant the path, or religion or teaching of the Bushi. The author had stated that the word "Bushi" might well be translated by the word "gentleman." He did not think a better translation of the word could have been found, for all that Englishmen looked upon as going to form the highest and noblest conception of what they meant when they used the word gentleman was conveyed by the word Bushi. It was loyalty to the Sovereign, trustfulness to the friend, truth, honour, courage and chivalry. If proof was wanted that chivalry was of the very essence of Bushido, what could be found better than that magnificent message which was sent by the Emperor himself after the taking of Port Arthur, when he told his soldiers to respect General Stoessel, who had done such good work for his own country. He thought that message of the Emperor of Japan, coming as it did at that particular moment, would live in history and never die. In the earlier part of the paper, the author had stated that the Chinese word "jen" might be translated love, but Baron Suyematsu confessed that the translation had given him some difficulty. He suggested to the author that the best translation of the word "jen" was Charity in the Pauline sense of the word — when St. Paul said "The greatest of these is Charity;" and if Baron Suyematsu would in future use that translation of the word, he did not think he would find any more difficulty. There was one remark in the paper which seemed to him to be pregnant with meaning. The author had stated that Chinese histories gave a bare record of facts, and had implied that they showed no political bias. That was perfectly true; and he had often wondered to himself whether it would not be better that some of the English histories should follow that example, and thereby get somewhere nearer to the truth of many events which had taken place in the past. Such confused and contradictory versions were at present obtained that people were hardly able to form any estimation of the truth. Shintoism, as the author had pointed out, was the aboriginal religion of Japan. He thought Baron Suyematsu would perhaps agree with him in saying that he might have gone one step further in defining it, by saying that it was indeed a form of Sun worship, coupled with the respect of ancestors. Worship of the Sun he believed formed an essential part of the more ancient forms of Shintoism; the whole of the fable of the Sun God, his hiding in the cave, and other of the original fables of the Japanese cosmogony all pointed in that direction. He thought the audience might congratulate the author on the great achievement of his fellow-countrymen which had been recorded within the last few hours. It might be said without exaggeration that those living in the present day were the witnesses of one of those crises which made a profound mark upon the history, not of one or two countries, but of the whole world. The successes they had heard of that day had been achieved in the face of difficulties of which those present could probably form no idea. The armies that were opposed to one another were the largest armies that had ever stood face to face since the history of the world began. The line of operations was 75 miles in length, 15 miles further than the distance between London and Oxford; and that those operations should have been successful, not in one nor in two parts, not in one corner nor in another corner, but along the whole extended line of 75 miles was a military achievement which had not its parallel in the history of the world.

The resolution of thanks, having been carried,

Baron SUYEMATSU, in reply, briefly acknowledged the compliment.

CORRESPONDENCE.

COTTON GROWING IN THE WEST INDIES.

In the *Journal of the Society of Arts* for February 13th, 1905, pp. 198-9, there is a note on "Cotton Growing in the West Indies." As this note is likely to give a wrong impression to readers as to the present position of efforts to resuscitate the cotton industry in the West Indies, I would desire to point out that the information contained in it is now obsolete.

The note is based, it is stated, on a report issued by the Colonial Office, but no hint is given of the fact that this referred to the year 1903, and cannot, therefore, contain the most recent information on the subject.

Since the expiration of the period under review in the note, considerable progress has been made in connection with cotton growing, full information in respect of which has been published in the *Agricul-*

tural News and the *West Indian Bulletin.* Copies of these are regularly communicated as issued.

I would quote the following extract from the presidential address delivered by me before the West Indian Agricultural Conference held at Trinidad on January 4–12 last. This contains the latest information in regard to cotton growing in the West Indies.

"The first of the recent experiments in cotton growing were started at St. Lucia in 1900. In the following year these experiments were extended to Barbados and the northern islands. In 1902 Messrs. Stendall and Wade began the cultivation of cotton on a commercial scale at St. Kitt's and Montserrat. The total area planted in all the islands in 1902 was 500 acres. This was increased in 1903 to 4,000 acres. During the year 1904 the area planted in Sea Island cotton, and now coming into bearing, was 7,243 acres, and in other varieties 4,438 acres, making a total of 11,681 acres. Valuable assistance was rendered by the British Cotton-growing Association in making grants of money and machinery; also in taking charge of the shipments of cotton and finding the best market for them. More recently the Association arranged for a visit to the West Indies by Mr. E. Lomas Oliver who rendered great service by explaining in detail the requirements of spinners in regard to uniformity in length of staple, colour, and fineness. The Imperial Department of Agriculture supplied 35,700 lbs. of seed of the best variety of Sea Island cotton at cost price. At present there are fifteen well-equipped cotton ginneries in working order. The prices obtained for West Indian Sea Island cotton during the past season have ranged from 12d. to 18d. per pound. The average price was 14½d. per pound. It is now recognised that West Indian Sea Island cotton is an article in good demand, and the industry shows every promise of being established on remunerative lines. It is probable that the crop of Sea Island cotton to be reaped from now to May next will reach about 5,000 bales (of 300 lb. each), of the value of £100,000. Details in regard to the general position and prospects of the cotton industry will be laid before the Conference.

D. MORRIS,
Commissioner of Agriculture for the West Indies.

Barbados,
February 2nd, 1905.

STREET TRAFFIC.

A few weeks ago (see *ante* December 30, 1904, p. 145) I saw some remarks in the *Journal* about wheeled traffic going along the left side of the road and foot traffic along the right side of the path, but I did not notice that anyone gave what is probably the real reason for the maintenance of that custom—namely, that it is more convenient in practice for the foot and wheeled traffic going the same way to be next one another.

C. F. WALSH.

OBITUARY.

HENRY LEE, J.P.—Mr. Henry Lee, who died at his house at Broughton-park on December 27th last, had been a member of the Society of Arts since 1872. He was the son of Mr. Lee Lee, a muslin manufacturer, and was born in 1817 at Chorley. He was apprenticed to Mr. Goodair, of Preston, a cotton manufacturer. Afterwards, when in partnership with Messrs. Tootal, he established the Sunnybank Cotton Spinning and Weaving Mills near Bolton, and became a pioneer in the application of steam power and automatic machinery to the production of fine and fancy fabrics of high quality. Mr. Lee was also a director, and for several years chairman, of Bolckow, Vaughan, and Co, Ltd., of Middlesborough, director of the Manchester and Salford Bank, and director and chairman of the Manchester Chamber of Commerce. He established schools for the benefit of the children of his workpeople, which were continued for more than 20 years after the passing of the Elementary Education Act of 1870. He was a member of Parliament for Southampton from 1880 to 1885, and throughout his life took the greatest interest in the education, promotion of thrift, and general improvement of the working classes.

G. J. MORRISON.—Mr. Gabriel James Morrison, M.I.C.E., who died on February 11th at the age of 65, was a member of the Society of Arts, and in May, 1903, he read a paper on "The Construction of Maps and Charts," for which he received the Society's silver medal.

The following particulars of Mr. Morrison's career in China are taken from the obituary notice in *The Times*:—He was a favourite pupil of Sir William Thomson (now Lord Kelvin), and was present with him at the laying of the first cable across the Atlantic ocean. He went out as engineer-in-charge of the first railway laid down in China. This railway ran between Shanghai and Wusung, and was very soon torn up by the Chinese Government, the materials being shipped over to the island of Formosa, where they were allowed to rust away. Mr. Morrison then established himself in business in Shanghai as a civil engineer, making frequent trips to Peking and into the interior of China, visiting officials and endeavouring to get a system of trunk lines laid. In 1885 he entered into partnership with Mr. F. M. Gratton, and the firm of Morrison and Gratton, as civil engineers and architects, was for many years connected with the largest and most important works carried out at Shanghai. The partnership was dissolved in 1902, when Mr. Morrison came to London and was associated with Sir John Wolfe Barry and Mr. Arthur J. Barry as consulting engineer of the Shanghai-Nanking line. During his residence in China he took a deep interest in public affairs and was for many years a member of the Shanghai Municipal Council, and major in command of the Shanghai volunteer corps.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

MARCH 15.—"Methods of Design in Mohammedan Art." By E. H. HANKIN. SIR GEORGE BIRDWOOD, K.C.I.E., C.S.I., Vice-President of the Society, in the chair.

MARCH 22.—"The Present Aspect of the Fiscal Question." By SIR CHARLES MALCOLM KENNEDY, K.C.M.G., C.B.

MARCH 29.—"British Woodlands." By the RIGHT HON. SIR HERBERT MAXWELL, Bart., M.P. R. C. MUNRO-FERGUSON, M.P., will preside.

APRIL 5.—"Ancient Architecture of the Great Zimbabwe." By RICHARD A. HALL.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

MARCH 16.—"Manipur and its Tribes." By T. C. HODSON (late I.C.S.).

COLONIAL SECTION.

Tuesday afternoons at 4.30 o'clock:—

MARCH 28.—The Manufactures of Greater Britain. —II. Australasia." By the HON. WALTER HARTWELL JAMES, K.C., Agent-General for and late Premier of Western Australia.

APPLIED ART SECTION.

Tuesdays, at 4.30 or 8 o'clock:—

MARCH 21, 8 p.m.—"West Country Screens and Rood Lofts." By F. BLIGH BOND, F.R.I.B.A. G. F. BODLEY, R.A., will preside.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

HERBERT LAWS WEBB, "Telephony." Four Lectures.

LECTURE I.—MARCH 13.—*Telephone Instruments.*—The telephone industry—The Bell telephone—Telephone receivers—Telephone transmitters—Evolution of the modern transmitter—Design of transmitters and receivers—Signalling appliances—Complete telephone instruments—Protective appliances—Special forms of telephones—Special uses of the telephone.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 13...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. Herbert Laws Webb, "Telephony." (Lecture I.)

Surveyors, 12, Great George-street, S.W., 8 p.m. Mr. E. Morten, "Surveyors' Reports and Certificates."

Geographical, University of London, Burlington-gardens, W., 8½ p.m.

Camera Club, Charing-cross-road, W.C., 8½ p.m.

Medical, 11, Chandos-street, W., 8½ p.m.

TUESDAY, MARCH 14...Aeronautical (at the HOUSE of the SOCIETY OF ARTS, John-street, Adelphi, W.C.), 8 p.m. 1. Mr. P. Y. Alexander, "Some Recent Experiments in Aerodynamics." 2. Mr. Eric Stuart Bruce, "The Shape of Navigable Balloons." 3. Mr. E. C. Hawkins, "Automatic Stability." 4. Mr. Alan A. Burgoyne, "Note on an Aluminium Kite."

Hellenic (in the Society of Antiquaries Rooms, Burlington-house, W.), 5 p.m.

Royal Institution, Albemarle-street, W., 5 p.m. Professor Pearson, "Some Recent Brometric Studies." (Lecture III.)

Medical and Chirurgical, 20, Hanover-square, W., 8½ p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Lord Brassey, "Shipbuilding for the Navy."

Photographic, 66, Russell-square, W.C., 8 p.m. Mr. S. D. Chalmers, "Some Results of Lens Testing."

Anthropological, 3, Hanover-square, W., 8½ p.m.

Colonial, Whitehall Rooms, Whitehall-place, S.W., 8 p.m. Sir Charles Bruce, "The Crown Colonies."

Horticultural, Vincent-square, S.W., 3 p.m. Rev. Prof. Henslow, "Bud Variation."

WEDNESDAY, MARCH 15...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. E. H. Hankin, "Methods of Design in Mohammedan Art."

Meteorological, 25, Great George-street, S.W., 7½ p.m. Mr. Richard Bentley, "The Growth of Instrumental Meteorology." 2. Exhibition of Meteorological Instruments.

Chemical, Burlington-house, W., 5½ p.m.

Microscopical, 20, Hanover-square, W., 8 p.m. Mr. J. E. Stead, "A Review of Work done by Metallographers."

Sanitary Engineers, 19, Bloomsbury-square, W.C., 7 p.m. Mr. T. B. Simmons, "Housing of the Working Classes."

British Archæological Association, 32, Sackville-street, W., 8 p.m.

THURSDAY, MARCH 16...SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Indian Section.) Mr. T. C. Hodson, "Manipur and its Tribes."

Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Dr. Otto Staff, "Contributions to the Flora of Liberia." 2. Mr. Rupert Vallentin, "Penguins and other Birds from the Falkland Islands; and Scratched Rocks from a Rockhopper's Rookery."

Royal Institution, Albemarle-street, W., 5 p.m. Prof. H. H. Turner, "Recent Astronomical Progress." (Lecture III.)

Optical, 20, Hanover-square, W., 8 p.m. Presidential Address.

Historical, Clifford's-inn Hall, Fleet-street, E.C., 5 p.m.

Numismatic, 22, Albemarle-street, W., 7 p.m.

Camera Club, Charing-cross-road, W.C., 8½ p.m.

FRIDAY, MARCH 17...Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting. 9 p.m., Sir Squire Bancroft, "Dramatic Thoughts: Retrospective—Anticipative."

Art Workers' Guild, Clifford's-inn Hall, Fleet-street, E.C., 8 p.m.

Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m.

Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m. Prof. David S. Capper, "First Report of the Steam-engine Research Committee."

SATURDAY, MARCH 18...Royal Institution, Albemarle-street, W., 3 p.m. Prof. J. J. Thomson, "Electrical Properties of Radio Active Substance." (Lecture II.)

Journal of the Society of Arts.

No. 2,730. VOL. LIII.

FRIDAY, MARCH 17, 1905.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

NOTICES.

NEXT WEEK.

MONDAY, MARCH 20, 8 p.m. (Cantor Lecture.) HERBERT LAWS WEBB, "Telephony," Lecture II.

TUESDAY, MARCH 21, 8 p.m. (Applied Art Section.) F. BLIGH BOND, F.R.I.B.A., "West Country Screens and Rood Lofts."

WEDNESDAY, MARCH 22, 8 p.m. (Ordinary Meeting.) SIR CHARLES MALCOLM KENNEDY, K.C.M.G., C.B., "The Present Aspect of the Fiscal Question."

Further details of the Society's meetings will be found at the end of this number.

EXAMINATIONS.

The number of entries for the Society of Arts Commercial Examinations to be held next month amount to 25,957, an increase of 4,367 on the numbers of last year—21,590. This total is made up as follows:—Advanced Stage 5,435, Intermediate 11,329, Elementary 9,193. The number of centres at which this year's examinations will be held is 383. Last year there were 346.

CANTOR LECTURES.

On Monday evening, March 13, Mr. HERBERT LAWS WEBB delivered the first lecture of his Course on "Telephony."

The lectures will be published in the *Journal* during the summer recess.

INDIAN SECTION.

On Thursday afternoon, March 16; SIR GEORGE BIRDWOOD, K.C.I.E., C.S.I., in the chair.

The paper read was "Manipur and its Tribes," by T. C. HODSON (late I.C.S.).

The paper and report of the discussion will be published in a future nnmber of the *Journal.*

THE ALBERT MEDAL.

The Council will proceed to consider the award of the Albert Medal for 1905 early in May next, and they, therefore, invite members of the Society to forward to the Secretary, on or before the 1st April, the names of such men of high distinction as they may think worthy of this honour. The medal was struck to reward "distinguished merit in promoting Arts, Manufactures, and Commerce," and has been awarded as follows in previous years:—

In 1864, to Sir Rowland Hill, K.C.B., F.R.S., "for his great services to Arts, Manufactures, and Commerce, in the creation of the penny postage, and for his other reforms in the postal system of this country, the benefits of which have, however, not been confined to this country, but have extended over the civilised world."

In 1865, to his Imperial Majesty, Napoleon III., "for distinguished merit in promoting, in many ways, by his personal exertions, the international progress of Arts, Manufactures, and Commerce, the proofs of which are afforded by his judicious patronage of Art, his enlightened commercial policy, and especially by the abolition of passports in favour of British subjects."

In 1866, to Michael Faraday, D.C.L., F.R.S., "for discoveries in electricity, magnetism, and chemistry, which, in their relation to the industries of the world, have so largely promoted Arts, Manufactures, and Commerce."

In 1867, to Mr. (afterwards Sir) W. Fothergill Cooke and Professor (afterwards Sir) Charles Wheatstone, F.R.S., "in recognition of their joint labours in establishing the first electric telegraph."

In 1868, to Mr. (afterwards Sir) Joseph Whitworth, LL.D., F.R.S., "for the invention and manufacture of instruments of measurement and uniform standards by which the production of machinery has been brought to a state of perfection hitherto unapproached, to the great advancement of Arts, Manufactures and Commerce."

In 1869, to Baron Justus von Liebig, Associate of the Institute of France, For. Memb. R.S., Chevalier of the Legion of Honour, &c., "for his numerous valuable researches and writings, which have contributed most importantly to the development of

food economy and agriculture, to the advancement of chemical science, and to the benefits derived from that science by Arts, Manufactures, and Commerce."

In 1870, to Vicomte Ferdinand de Lesseps, Member of the Institute of France, Hon. G.C.S.I., "for services rendered to Arts, Manufactures, and Commerce, by the realisation of the Suez Canal."

In 1871, to Mr. (afterwards Sir) Henry Cole, K.C.B., "for his important services in promoting Arts, Manufactures, and Commerce, especially in aiding the establishment and development of International Exhibitions, the Department of Science and Art, and the South Kensington Museum."

In 1872, to Mr. (afterwards Sir) Henry Bessemer, F.R.S., "for the eminent services rendered by him to Arts, Manufactures, and Commerce, in developing the manufacture of steel."

In 1873, to Michel Eugène Chevreul, For. Memb. R.S., Member of the Institute of France, "for his chemical researches, especially in reference to saponification, dyeing, agriculture, and natural history, which for more than half a century have exercised a wide influence on the industrial arts of the world."

In 1874, to Mr. (afterwards Sir) C. W. Siemens, D.C.L., F.R.S., "for his researches in connection with the laws of heat, and the practical applications of them to furnaces used in the Arts; and for his improvements in the manufacture of iron; and generally for the services rendered by him in connection with economisation of fuel in its various applications to Manufactures and the Arts."

In 1875, to Michel Chevalier, "the distinguished French statesman, who, by his writings and persistent exertions, extending over many years, has rendered essential services in promoting Arts, Manufactures, and Commerce."

In 1876, to Sir George B. Airy, K.C.B., F.R.S., Astronomer Royal, "for eminent services rendered to Commerce by his researches in nautical astronomy and in magnetism, and by his improvements in the application of the mariner's compass to the navigation of iron ships."

In 1877, to Jean Baptiste Dumas, For. Memb. R.S., Member of the Institute of France, "the distinguished chemist, whose researches have exercised a very material influence on the advancement of the Industrial Arts."

In 1878, to Sir Wm. G. Armstrong (afterwards Lord Armstrong), C.B., D.C.L., F.R.S., "because of his distinction as an engineer and as a scientific man, and because by the development of the transmission of power—hydraulically—due to his constant efforts, extending over many years, the manufactures of this country have been greatly aided, and mechanical power beneficially substituted for most laborious and injurious labour."

In 1879, to Sir William Thomson (now Lord Kelvin), LL.D., D.C.L., F.R.S., "on account of the signal service rendered to Arts, Manufactures, and Commerce, by his electrical researches, especially with reference to the transmission of telegraphic messages over ocean cables."

In 1880, to James Prescott Joule, LL.D., D.C.L., F.R.S., "for having established, after most laborious research, the true relation between heat, electricity, and mechanical work, thus affording to the engineer a sure guide in the application of science to industrial pursuits."

In 1881, to August Wilhelm Hofmann, M.D., LL.D., F.R.S., Professor of Chemistry in the University of Berlin, "for eminent services rendered to the Industrial Arts by his investigations in organic chemistry, and for his successful labour in promoting the cultivation of chemical education and research in England."

In 1882, to Louis Pasteur, Member of the Institute of France, For. Memb. R.S., "for his researches in connection with fermentation, the preservation of wines, and the propagation of zymotic diseases in silkworms and domestic animals, whereby the arts of wine-making, silk production, and agriculture have been greatly benefited."

In 1883, to Sir Joseph Dalton Hooker, K.C.S.I., C.B., M.D., D.C.L., LL.D., F.R.S., "for the eminent services which, as a botanist and scientific traveller, and as Director of the National Botanical Department, he has rendered to the Arts, Manufactures, and Commerce by promoting an accurate knowledge of the floras and economic vegetable products of our several colonies and dependencies of the Empire."

In 1884, to Captain James Buchanan Eads, "the distinguished American engineer, whose works have been of such great service in improving the water communications of North America, and have thereby rendered valuable aid to the commerce of the world."

In 1885, to Mr. (afterwards Sir) Henry Doulton, "in recognition of the impulse given by him to the production of artistic pottery in this country."

In 1886, to Samuel Cunliffe Lister (now Lord Masham), "for the services he has rendered to the textile industries, especially by the substitution of mechanical wool combing for hand combing, and by the introduction and development of a new industry—the utilisation of waste silk."

In 1887, to HER MAJESTY QUEEN VICTORIA, "in commemoration of the progress of Arts, Manufactures, and Commerce throughout the Empire during the fifty years of her reign."

In 1888, to Professor Hermann Louis Helmholtz, For. Memb. R.S., "in recognition of the value of his researches in various branches of science and of their practical results upon music, painting, and the useful arts."

In 1889, to John Percy, LL.D., F.R.S., "for his achievements in promoting the Arts, Manufactures, and Commerce, through the world-wide influence which his researches and writings have had upon the progress of the science and practice of metallurgy."

In 1890, to William Henry Perkin, F.R.S., "for his discovery of the method of obtaining colouring

matter from coal tar, a discovery which led to the establishment of a new and important industry, and to the utilisation of large quantities of a previously worthless material."

In 1891, to Sir Frederick Abel, Bart., G.C.V.O., K.C.B., D.C.L., D.Sc., F.R.S., "in recognition of the manner in which he has promoted several important classes of the Arts and Manufactures, by the application of Chemical Science, and especially by his researches in the manufacture of iron and of steel; and also in acknowledgment of the great services he has rendered to the State in the provision of improved war material, and as Chemist to the War Department."

In 1892, to Thomas Alva Edison, "in recognition of the merits of his numerous and valuable inventions, especially his improvements in telegraphy, in telephony, and in electric lighting, and for his discovery of a means of reproducing vocal sounds by the phonograph."

In 1893, to Sir John Bennet Lawes, Bart., F.R.S., and Sir Henry Gilbert, Ph.D., F.R.S., "for their joint services to scientific agriculture, and notably for the researches which, throughout a period of fifty years, have been carried on by them at the Experimental Farm, Rothamsted."

In 1894, to Sir Joseph (now Lord) Lister, F.R.S., "for the discovery and establishment of the antiseptic method of treating wounds and injuries by which not only has the art of surgery being generally promoted, and human life saved in all parts of the world, but extensive industries have been created for the supply of materials required for carrying the treatment into effect."

In 1895, to Sir Isaac Lowthian Bell, Bart., F.R.S., "in recognition of the services he has rendered to Arts, Manufactures, and Commerce by his metallurgical researches and the resulting development of the iron and steel industries."

In 1896, to Prof. David Edward Hughes, F.R.S., "in recognition of the services he has rendered to Arts, Manufactures, and Commerce, by his numerous inventions in electricity and magnetism, especially the printing telegraph and the microphone."

In 1897, to George James Symons, F.R.S., "for the services he has rendered to the United Kingdom by affording to engineers engaged in the water supply and the sewage of towns a trustworthy basis for their work, by establishing and carrying on during nearly forty years systematic observations (now at over 3,000 stations) of the rainfall of the British Isles, and by recording, tabulating, and graphically indicating the results of these observations in the annual volumes published by himself."

In 1898, to Professor Robert Wilhelm Bunsen, M.D., For. Memb. R.S., "in recognition of his numerous and most valuable applications of Chemistry and Physics to the Arts and to Manufactures."

In 1899, to Sir William Crookes, F.R.S., "for his extensive and laborious researches in chemistry and in physics; researches which have, in many instances, developed into useful practical applications in the Arts and Manufactures."

In 1900, to Henry Wilde, F.R.S., "for the discovery and practical demonstration of the indefinite increase of the magnetic and electric forces from quantities indefinitely small, a discovery now used in all dynamo machines; and for its application to the production of the electric search-light, and to the electro-deposition of metals from their solutions."

In 1901, to HIS MAJESTY THE KING, "in recognition of the aid rendered by His Majesty to Arts, Manufactures, and Commerce during thirty-eight years' Presidency of the Society of Arts, by undertaking the direction of important exhibitions in this country and the executive control of British representation at International Exhibitions abroad and also by many other services to the cause of British Industry."

In 1902, to Professor Alexander Graham Bell, "for his invention of the Telephone."

In 1903, to Sir Charles Augustus Hartley, K.C.M.G., "in recognition of his services, extending over 44 years, as Engineer to the International Commission of the Danube, which have resulted in the opening up of the navigation of that river to ships of all nations, and of his similar services, extending over 20 years, as British Commissioner on the International Technical Commission of the Suez Canal."

In 1904, to Walter Crane, "in recognition of the services he has rendered to Art and Industry by awakening popular interest in Decorative Art and Craftsmanship, and by promoting the recognition of English Art in the form most material to the commercial prosperity of the country."

PROCEEDINGS OF THE SOCIETY.

COLONIAL SECTION.

Tuesday afternoon, February 28th; the Right Hon. VISCOUNT RIDLEY in the chair.

The CHAIRMAN said as one who had spent a certain amount of his time, and not, he might say, the least pleasant part of his time, in Canada, he had very great pleasure in taking the chair that afternoon. Ever since his connection with the country his interest in the affairs of the Dominion had been unceasing. He thought that all would be agreed that the Society of Arts, in arranging a series of papers, of which the present one was the first, upon the industries of our colonies, was performing a very great service. He thought it was a strange thing that England did not take a more active interest in the affairs of the Empire. However, without touching upon that dangerous subject, the Fiscal question, he thought he might say, with the agreement of everybody, that at the present moment attention was being very considerably fo-

cussed upon the position of the colonies and their industries, and that papers such as the one about to be read were of very great value in disseminating information on and stimulating interest in the subject.

The paper read was—

THE MANUFACTURES OF GREATER BRITAIN.

I.—DOMINION OF CANADA.

By C. F. Just.
Canadian Government Service, London.

It is impossible to overrate the value of the educational work carried on for many years by the Colonial and Indian Sections of the Society of Arts. To a student of the British Empire a review of that work forms a useful index to the widening of knowledge and interest in our Colonies which has taken place in the Mother Country. General papers on the Colonies have had their day, and have yielded place to treatises on special colonial characteristics and interests, phases of life and progress, economic and political. In this respect the present series of papers marks a fresh departure in the education of our fellow subjects at home in the progress of the outlying portions of the Empire. There is no need, therefore, to speak of Canada in general terms. Her agricultural development is well known—it has become the envy of the world; her forests and fisheries are exploited on an unexampled scale; her mineral wealth, while as yet hardly touched, is known to be vast, and is to be the reward of enterprise in the immediate future. Few, however, even of the best instructed, think of Canada except as a rich storehouse of products of the soil, the forest, mine, and stream.

My theme this afternoon is Canada's manufacturing industries. Canada is unquestionably the most advanced industrially of the self-governing colonies. The popular view here is that at best Canada's manufacturing resources are as limited as her population is limited—I hope to show you the contrary—least of all is the idea entertained of her future as a competitor with other countries in great industrial tournaments; and yet nothing less than this is certain within the immediate future. Living alongside the most progressive and industrial nation of the world, Canadians have seen what manufactures can accomplish in the building up of the State within a short span of time; they have rightly felt that, with no meaner country than that of their neighbours, the same industrial destiny must be theirs in good time, and, as events are proving, rather sooner than later.

The stirring of national life, which found practical expression in the Act of Confederation in 1867, fed the natural desire of Canadians to become a self-contained modern State. The refusal of the United States to renew the Reciprocity Treaty (1855-66), under which a large trade had been built up in that market, hit Canadian interests hard; new outlets had to be found for their products, but it served only to strengthen the resolve of the people for economic independence. A period of ten years' depression followed. It was accentuated by the high-tariff policy of the United States, with its corollary of dumping surplus production on the Canadian market, to the great disadvantage of the Canadian manufacturers struggling to build up local industries. In Canada this period was also one of experiments in low revenue tariffs, which, for reasons of self-defence, it was found necessary to increase from time to time.

A National Policy.

Circumstances at length brought the tariff policy of the country to an issue. Canadians had to deal with an actual condition, not a theory, and they decided ultimately to adopt a tariff which would protect and foster home industries, as set forth in the famous resolution moved by Sir John Macdonald in the House of Commons in 1878:—

> "That this House is of the opinion that the welfare of Canada requires the adoption of a national policy which, by a judicious readjustment of the tariff, will benefit and foster the agricultural, the mining, the manufacturing, and other interests of the Dominion; that such a policy will retain in Canada thousands of our fellow countrymen now obliged to expatriate themselves in search of the employment denied to them at home, will restore prosperity to our struggling industries now so sadly depressed, will prevent Canada being made a sacrifice market, will encourage and develop an active inter-provincial trade, and moving, as it ought to do, in the direction of a reciprocity of tariffs with our neighbours, so far as the varied interests of Canada may demand, will greatly tend to produce for this country eventually reciprocity of trade."

This national policy, broadly speaking, has held the field from that day to this. Its

expediency has been confirmed under the ceaseless aggressive high-tariff policy of the United States of the last three decades, which, under the McKinley and subsequent tariffs, was framed with special reference to Canadian primary and other industries competing with their own. Canadian endurance was tried in the fire. The situation called for the complete readjustment of Canada's markets. Canada's salvation was found to lie in developing her market in the Mother Country, which offered stable conditions of trade; these she could never expect to enjoy from the United States. The results have secured for her both a great permanent increase of trade, and have made her economically independent of the United States. To-day, trade depressions and financial crises across the frontier no longer seriously affect business in the Dominion. Canada also has incidentally more than regained the volume of her trade exchanges even with the United States, with this improvement, that this trade is now on a footing which it is possible for Canada to control and regulate to her advantage as circumstances may dictate. But I am anticipating. The National Policy brought great and immediate industrial activity in its train; the Canadian home market received at once the benefit of the vast expenditure on the Canadian Pacific Railway and other public works, and of the rapid settlement of the new prairie *hinterland* thrown open by railways to fresh immigrants.

The Census of 1881 already reflects this growth of Canada's industrial position. It was roughly double that of 1871 in the capital invested, the wages paid, the persons employed, and in the consumption of home-manufactured products. A number of causes, however, conspired to retard the expansion in manufactures that was expected. Among them must be mentioned the check to settlement in the West due to restrictive measures imposed in Europe on emigration, to the results of wild land speculation in the West which was very general, to the disturbances which led to the North-West Half-breed Rebellion of 1885; and, above all, to the continued drain of the native-born population to the United States, now happily at an end. It is not generally known in this country how serious this drain has been in the past, but an estimate of 3,000,000 people of Canadian origin and of their descendants living in the United States would not be wide of the mark. This fact alone explains the need of the opening up of Western Canada for settlement, and of developing the industries of the country to attract and retain population in the Dominion. It is also now recognised that inexperience of the working of economic conditions, imprudent additions to the tariff, threw burdens upon industry which hampered enterprise; nevertheless, the progress of manufactures shown in the Census of 1891, and again of 1901, must impress every thoughtful person with the enterprise of Canadian captains of industry, and the increasing diversity and importance of industrial production in the Dominion.

With the advent to power of the Laurier Ministry in 1896, important readjustments of the tariff took place. The anachronisms referred to were pruned away, and relief was granted in a multitude of cases. Industry at once responded to the change. Great advantage also, political and economic, attended the introduction of the British preference policy. In Canada its effect was to cheapen the cost of living all round—as the rebate on British imports influenced the prices of American imports and of home-made articles—and to leave in the pockets of the people millions of dollars for useful expenditure. Employment became and has remained most active ever since, and the sufficiency of the new tariff policy has been epitomised recently by the *Toronto Globe* in the comment, "that the supply of labour has been found *inadequate* is the best proof that the tariff is *adequate*."

Simultaneously with the year 1896 commenced that extraordinary improvement in Canada's position which has continued up to the present time, the end of which we believe to be still far off. The drain of population to the United States has ceased; immigration has poured into the country in a fertilising stream. The increase in population during this period has been estimated recently by Sir Richard Cartwright at no less than 1½ millions. Trade and commerce has doubled (1896, 231,601,000 dols.; 1903, 459,640,000 dols.); the revenue has doubled (1896, 33,978,000 dols.; 1904, 66,037,000 dols.), providing surpluses aggregating some 40,000,000 dols. in eight years. The Public Debt has not only been reduced, but large expenditures on remunerative public works have been met out of surplus revenue without adding a shilling to the burdens of the tax-payer. The general manager of the Canadian Bank of Commerce, speaking at the annual meeting in January last on the general position of the country said:—

"During the last ten years the business of banking in Canada has increased as much as in the preceding *eighty years*. The deposits of the people have not merely grown enormously in the aggregate, but they have grown from 52 dols. 16 cents to 99 dols. per head of population."

CENSUS RETURNS.

In no direction has the improvement been felt more than in Canada's manufacturing industries. The following Table shows the statistical position of their growth by 1901 compared with 1891 and 1881, and the distribution of the industrial establishments (1901) *by Provinces*:—

1. Consolidation, shown in decrease (11 per cent.) of the number of establishments of five *employés* and over.

2. Great increase of capital invested (48·83 per cent.).

3. Not a corresponding increase in value of products per dollar of capital (1901, 1·03; 1891, 1·21 per dollar).

4. Decrease in average wage (5·04 per hand per annum).

5. Increase in value of product per *employé* (14·76 against 13·34 in 1891.

During the four years that have elapsed, Canada's industrial progress has moved at such a greatly accelerated pace as to make the figures of 1901 no longer reliable. An authoritative writer on the subject, in the *Toronto Globe* of July last, estimates the manufacturing position to-day at 15,000 factories, representing invested capital of 500,000,000 dols., producing goods of a like amount, and employing half a million of people. It is now estimated that 40 per cent. of Canada's population, taken at six millions, is dependent upon her manufacturing industries. (See Table B, p. 446.)

	1881.	1891.	1901.*
Capital Invested	$165,302,000	$296,350,000	$441,353,060
Value of Products	$309,676,000	$359,082,000	$452,775,771
Number of Establishments............	—	12,404	11,126
Number of Employés	254,935	269,093	306,694
Wages Paid	$59,429,000	$78,492,345	$88,143,472
Average Wage.......................	$254	$292·44	$287·40

* It should be observed that the figures of the last two censuses refer to *manufacturing* industries only, and that the basis of enumeration excludes all industrial establishments employing under five hands. The figures of 1881 are on the old basis—*i.e.*, they include such industries as dairy factories, abbatoirs, &c., and *all* establishments affording industrial or hand employment, *however small*.

Provinces.	Number of Establishments.	Capital Invested.	Cost of Materials.	Value of Products.
		Dollars.	Dollars.	Dollars.
British Columbia	392	22,901,892	7,246,684	19,447,778

Totals for Canada*	14,650	446,916,487	266,527,858	481,053,875

* Including dairy factories.

In Table A (p. 445) will be found an analysis of the comparative position in 1891 and 1901 of the Canadian manufacturing industries classified by *groups*, from which a useful survey of the diversity of the manufactures and the relative importance of each respective branch can be obtained.

The Dominion statistician summarises his conclusions in regard to the Census of 1901* as follows:—

* Statistical Year-book of Canada, 1903.

TABLE A.—MANUFACTURES OF 1891 AND 1901, CLASSIFIED AND COMPARED.

Watchmaking and jewellery	50	1,416,609	39	1,714,153

DIVERSITY AND WIDE DISTRIBUTION OF INDUSTRIES.

Looking closely into this Table, we recognise how successfully Canada has provided herself with the great basic industries of a modern State, and with a multitude of important subsidiary industries, so that there is scarcely an article connected with these great fields of manufacture which is not made well and cheaply in Canada. Obviously, Canada's manufacturing industries are almost entirely situated in the eastern half of the Dominion. A striking feature also is their wide distribution throughout that region, carried on in a multitude of generally small centres, of which they form the *raison d'être*. This distribution is possible owing to the general distribution of raw material necesssary for the industries, to the supply of cheap power, and transportation facilities by water and rail which permit the cheap assembling of material, and the distribution of the finished product to the home market and for export. This situation in a country of great distances is highly favourable to the success of industrial undertakings generally, and to the prosperity of agriculture, and, indeed, of all local interests. A few illustrations will explain this more clearly.

Canada's iron industry—to which I will refer in detail later on—is represented by 18 blast furnaces and several steelmaking plants, located at nine different points in Nova Scotia, Quebec, and Ontario. Of the importance of the hundred and one subsidiary industries dependent on iron and steel, the census returns furnish conclusive evidence. Of these the engineering industry is notable for its growth during the last five years, and for its ability now to undertake large and complicated work. Many new establishments are also under construction in most of the chief centres. I give one example of the latter class, viz., the Canada Car Company at Montreal, with a capital of 3,000,000 dols. The daily capacity of the works will be some 60 wooden and steel freight cars and passenger coaches, besides pressed steel frames for another 60 cars, employing 2,000 men. This concern, the outcome of the building of the new trans-continental railway, has received orders already for 15 cars a day for five years, *i.e.*, 24,000 cars. In textiles, the cotton industry comprises 26 mills, with an aggregate of 500,000 spindles, and 12,000 power looms scattered between Halifax, Nova Scotia, and Hamilton, Ontario, with its chief centres in the province of Quebec. Prior to 1878 only coarse goods could be made, but now the mills excel in many of the finer lines, and they export also a part of their output to China and the Far East. Dependent industries, such as whitewear, shirts, collars, &c., are well-advanced in the principal towns. The woollen industry is represented by 300 mills, in as many centres, making cloths, knitted goods, carpets, &c. These mills are situated principally in Ontario and Nova Scotia. Subsidiary factories of ready-to-wear clothing, mantles, hosiery, &c., employing thousands of hands, are to be found throughout the eastern provinces. Canada's oldest industry—lumbering and saw mills—has grown to enormous proportions, and is followed in every place and corner of the Dominion. The wood-pulp industry with 35 mills, and the papermaking with 40 mills, are well distributed, and every indication points to an industry of the first importance being built up in the immediate future. Furniture, another characteristic industry, with 200 factories, mostly in Ontario, has already established a flourishing export trade; the same can be said of musical instruments, represented by 50 factories, which compete successfully with their German rivals. Boots and shoes are one of Canada's special industries, and rivals its American counterpart in organisation and equipment, and in the cheapness and excellence of its products. Quebec is the stronghold of this trade with 250 factories. Harness and saddlery and leather are again important industries in that province and in Ontario.

The tobacco and cigar industry, with 131 factories, is located in Montreal, Quebec, Toronto, and Hamilton. The canning of fish, fruit, vegetables, and meat, is widespread in Ontario and the maritime Provinces, and its 1,200 factories are generally to be found in the smaller centres; Canada's sugar industry is carried on in four refineries at Halifax and Montreal, and in Vancouver, on the Pacific, the raw material coming chiefly from the British West Indies. The beet sugar industry has also been established of late, with four factories in Ontario, and two in Alberta, North-West Territory. Portland cement making in Ontario and Quebec is rapidly developing, with nine companies turning out 1,500,000 barrels a year; six further concerns are under construction, capable of a like capacity. The local consumption of cement is as high as it is in Germany, and the prospect of an export trade is promising All the works are of the most

up-to-date type, with rotary kilns, and are most favourably located in respect of raw material, cheap power, and water transportation.

Incidentally Canada has built up an export trade in her manufacturing industries of the value of over 20,000,000 dols in 1904. It is true this represents but one-twelfth of the whole export trade, but the character of the articles it comprises is significant, the chief items being agricultural implements, machinery, sewing machines, typewriters, iron and steel manufactures, electrical apparatus, leather, boots and shoes, furniture, pianos, wood pulp and paper, carriages, bicycles, cotton and woollen goods.

The development of manufactures is beyond the capacity of the present local capital, and the supply of skilled labour to grapple with satisfactorily; and the position has become one which offers admirable opportunities for new comers. An earnest of the situation is to be found in the growing imports which in 1904 reached the value of 156,000,000 dols. in dutiable articles, and of 95,000,000 dols. in free goods. Upwards of one half of these imports came from the United States, consisting largely of goods which could be produced in Canada with equal facility.

American Capital in Canadian Industries.

American enterprise has become alive for some time to the manufacturing possibilities of the future in the Dominion. Tentative investments, amounting, it is estimated, to 100,000,000 dols., in industrial production of various kinds, have paved the way for a more comprehensive invasion. It is undoubted that American foresight has proved beyond peradventure the richness of the natural inheritance of Canada, and has done much to awaken in Canadians themselves a belief in its potentialities.

The iron and steel enterprises in Ontario at the Sault Ste. Marie (the "Soo"), and in Nova Scotia, at Sydney, were initiated, and are still largely supported by American capital. The Steel Trust of the United States is known to have made large purchases of mineral lands, and has arranged to put up an immense plant at Port Colborne, Lake Erie, to employ 3,000 hands. Another American enterprise is the Canadian Steel and Coal Company, with a capital of 6,000,000 dols., possessing large properties in iron ore and coal lands. Similar support is also being given to copper, mining, and to developing oil wells, asbestos, mica, and nickel deposits, and to reduction works and other metallurgical processes.

The United States and British Preference.

It is no secret that much of this recent American enterprise in Canada is directly due to the British preference policy. Americans fear this policy, if pressed and developed, will result in the loss to them of much of their trade with the British Empire, and that Canada, with like resources, possesses exceptional opportunities for taking the place of the United States. "Forewarned is forearmed," and so during the last few years a systematic transfer of American manufacturing to Canada has taken place for the double event, *i.e.*, Canada's home and foreign markets. Leading American firms of agricultural machinery have united to put up jointly works employing thousands of hands at Hamilton, Brantford, Stratford, and Toronto for the home and export trade; sewing machine factories in Quebec; locomotive, rolling stock and bridge-building works at Montreal and Toronto; general engineering works for the manufacture of machinery of all kinds—for mining, electrical installation, sugar refining; woollen mills, factories for rubber goods, paint, cereal foods, pork packing; cold storage plants, &c.

In many instances Americans have bought up shares in leading Canadian manufacturing concerns. In regard to timber and wood pulp lands Americans have been specially active in acquiring control of raw material and water powers for those industries in the eastern provinces; American capital also is largely invested in the new Canadian power works at Niagara, Shawinigan, the "Soo," Fort William, and at other points. Indeed, great credit is due to Americans for their shrewdness in turning Canada's prosperity, actual and prospective, to profitable account. "While it matters little to Canadians from a commercial standpoint," says the *Glasgow Herald*, "whether capital comes from America or from Great Britain, there are points of view which make it matter for regret that Englishmen are not taking up these advantages with greater interest."

British Investments.

Apart from investment in Government and municipal securities, railway bonds, &c., the British public at home remain indif-

ferent to Canadian *industrial* investments, preferring risky ventures in South America and equally doubtful quarters when there are such unlimited opportunities in Canada, immeasurably safer, far more profitable, and tending at the same time to build up and strengthen the greatest of the Empire's colonies. It is not denied, of course, that British investment does take place, but, it is feared, too frequently without a proper sense of selection, and in enterprises that are promoted without reference to their success. Speaking on this point a recent *Times* correspondent emphasises the fact that "the American investing in Canada seldom does so as a mere speculation, the results of which he leaves in the hands of others. He comes himself and watches the application of the capital which he or his friends have determined to apply to a given undertaking." In practice, therefore, the American makes safer and much more profitable investments than the Englishman, to whom, of course, the same opportunities are open.

It is not to be inferred that all Canadian and American investments have been fortunate: experience of the two ventures in the iron and steel industry at the "Soo" and at Sydney are cases in point: the causes, however, of their initial lack of success have been entirely due to over capitalisation, lack of technical knowledge, and management.* "There are many directions," says Mr. Jeans,† of the British Iron Trades Association, "both in East Canada and in West, in which capital can be safely invested, but two things are essential to the ultimate success of such investments; first, that the conditions and outlook of the country shall be thoroughly mastered in their several aspects, and, secondly, that the best advice and experience possible should be at the command of the investor." A similar opinion also has been expressed by Sir William White,‡ who visited Canada with the Institute of Civil Engineers last year, to the effect that he and his friends had seen enough to make it certain that in schemes "for the construction of new railways, improvement of waterways, the utilisation of numerous sources of water power for industrial purposes and the execution generally of engineering works, a splendid field was to be found in Canada for the investment of British capital."

* *Canadian Mining Review*, Ottawa, 1903.

† "Canada's Resources and Possibilities." London, 1904.

‡ *The Times*, January 11th, 1905.

INDUSTRIAL OPENINGS FOR SMALL CAPITAL.

Before leaving the subject of British investments in Canada I would like to say a word regarding the man of comparatively small capital—say of a few hundreds to £2,000 or £3,000—with some manufacturing experience, or, at any rate, a good business training, and, above all, judgment and energy. Canada owes much of her present position to the small man. Her leading manufacturers of to-day have risen from small beginnings, and Canada, above all countries, is still the field for such men to-day. This elementary fact cannot be insisted upon too strongly, and for the following reasons. The progress of the country is self-evident and assured; its main source lies in the rapid settlement of the great prairie regions in the West, where wealth is created rapidly, and on a great scale. The demand of the West has already stimulated manufacturing in Canada beyond all precedent, and an ever-increasing volume of orders has to be filled from abroad. An expenditure within the next five or six years of at least £40,000,000 on railways and public works *alone* will benefit and stimulate every interest and every manufacturing centre.

At the present rate of increase it is expected that by 1914 the population of Canada will be not less than ten millions of people. This decade cannot help being a golden age for Canadian manufacturers, small and great. New capital must come from outside, and it will come. Here, then, are the conditions and opportunities for men of the right stamp. Let us take Ontario, the most industrially developed province of the Dominion, and one ideally situated for the small working intelligent investor I have in mind. This is what a leading bank manager had to say last month as to the position of Ontario*:—

"The reports from towns and cities in Ontario with few exceptions indicate a large and prosperous volume in trade and manufacturing, not markedly different from that of the previous year. The maintenance of this high volume has doubtless several explanations, but the prominent reasons seem to be the increasing demand for all classes of goods from the West and the confidence in the immediate future of Canada, in view of the immigration, the extensive railroad building, and the fact that the outside world begins to understand the opportunities we have to offer to energy."

An official enquiry instituted by the Ontario Government as to the industrial openings in

* Annual Meeting of the Canadian Bank of Commerce, Toronto, January, 1905.

the cities, towns, and villages of Ontario in 1903 and 1904 supplies valuable information. The new industries most in demand are canning factories, which are asked for by no less than twenty towns and villages. The same remark applies to hardware industries, while the towns in the north hold out inducements for woodworking establishments, woollen mills, flour mills, evaporators for fruit and vegetables, pork-packing establishments, machine shops, brick and tile yards, and cordage and twine factories, &c. Exemption from taxes, free sites and free water-power are mentioned in many instances as attractions offered by the municipalities to the industries which they desire to secure. Many of the openings are, of course, peculiar to Canada, and of a character which must be examined with caution, but it is evident that where the selection is so wide, the opportunity exists of finding openings suitable to the capacity and circumstances of most people. From my own repeated personal investigations into this matter on the spot, I am more than confirmed in this opinion.

Briefly, then, I would advise those desiring to interest themselves to pay a visit to Canada and carefully look around before committing themselves definitely in any direction: It would be at the very least an inexpensive and invigorating holiday. The best and most disinterested advice is to be obtained by preference with the help of the general managers of the leading Canadian chartered banks in Montreal and Toronto. These gentlemen are thoroughly posted as to existing firms looking for fresh capital for business extensions, as well as in the matter of new industries; and in association with the managers of their local branches they are in a position to usefully advise and safeguard the interests of any capitalist, small or great, who goes out properly accredited. No doubt much useful advice could be had also from the officials of the various local Chambers of Commerce. Investors would thus be able to judge for themselves as to any proposition submitted to them, and have the assurance that they were making the right decision.

What is so true of Ontario is equally true of the other provinces. In the United Kingdom the office of the High Commissioner for Canada is well equipped with information and advice on all such matters and is ready to be helpful. There are also the Canadian Government agencies in the principal centres, Liverpool, Birmingham, Bristol, Cardiff, Manchester, Leeds, Glasgow, Dublin, Belfast, available for the same purpose.

Labour Situation.

The development of manufactures has outstripped the supply of skilled labour in every department, notwithstanding the considerable annual immigration of such labour from outside countries. It has created a scarcity which handicaps manufacturers in keeping pace with their business. Competent workers can be readily absorbed in considerable numbers with the certainty of permanent employment. Unskilled and partially-trained labour is usually procurable locally; wages in all industries have risen; they are about the same prevailing in the United States, but with this advantage that in Canada the cost of living is lower and a higher standard of comfort is enjoyed with opportunities for saving money not realisable here. The classes of workers in request may be inferred generally from the list of prominent industries already given (page 446). The demand is acute for mechanics for agricultural implements and carriage factories, engine and boiler making, and the allied engineering industries, car works, machinists, stove and foundry moulders, men for the boot and shoe and shirt and collar factories, for the furniture and upholstery trades; also female labour for boots and shoes, garments, whitewear, furs, woollens, spinners and weavers. Mr. George Drummond* recently put very pithily the actual and prospective labour needs of Canadian industry, as represented by the number of workers required to produce a reasonable production, 40 per cent., of the present imports of partially and wholly manufactured goods. This proportion is equal to 60,000,000 dols., and on the basis of the last census returns, would call for an army of 42,000 workers to produce. These workers, added Mr. Drummond, with their dependents would in the aggregate form a city of the size, if not of the wealth of Toronto, consuming at least 20,000,000 dols. worth of products annually.

A word is also due to Canadian labour-organisation. The unions hitherto have been on an *international* rather than on a *national basis*, and the 1,500 organisations are largely affiliated with similar bodies in the United States; the latter with a greater preponderance of members and funds, control the psition, and not always, it is believed, especially

* President's Annual Address, Canadian Manufacturers' Convention, Montreal, September, 1904.

of late years, to the best interest of the Canadian workers. There was less objection to this connection as long as Canada was undeveloped industrially; but it is obvious, now that she has outgrown that state, and that the interests of Canadian capital and labour are commercially opposed to and competitive with outside labour and capital, that the time for independent national labour unions is come.

The Ministry of Labour.

With commendable prevision the Canadian Government have felt its responsibility and prepared for these and other labour problems and questions which must attend industrial growth. They have created a Minister of Labour, with a seat in the Cabinet, and have formed a Department which occupies itself with the systematic collection and publication, in an official gazette, of labour statistics and of practical information, special and general, valuable alike to the capitalist and to the worker; it investigates industrial disputes, and promotes their settlement under a Conciliation Act; it secures the payment of fair wages to all employed on public contract work, the influence of which regulations is directed against sweating, and is helping materially to set a standard of wages throughout the Dominion. The Department conducts enquiries into the labour questions arising out of immigration, into existing and new industries and into their social and economic effect. Most practical results have thus been obtained and the work of the Department may be regarded as affording the best guarantee for stability and harmony in Canadian industrial conditions.

Canadian Manufacturers' Association.

Canadian capital is well organised, and on a *national* basis. I must not omit to refer here to the Canadian Manufacturers' Association, which has done so much to bring Canada's potentialities to the front. Five years ago this body was reorganised and has to-day a membership of 1,500, including the most influential and far-sighted captains of industry in the Dominion, who are not only manufacturers of goods, but who "manufacture Canadian enthusiasm, Canadian sentiment, a spirit of independence and a spirit of national pride." The Association is to-day, without a doubt, the most powerful organisation in Canada. The central offices are in Toronto, in close touch with the provincial branches. Standing committees deal with railway and transportation, legislation—federal and local tariff, commercial intelligence and trade expansion, labour and the settlement of disputes, insurance, &c. The greatest efficiency is secured on behalf of the interests represented. An official organ, *Industrial Canada*, is issued and widely circulated free of charge among the Chambers of Commerce in the Empire, the Imperial Consular service, and other similar bodies. For all who wish to keep in close touch with the trend of Canadian enterprise, resources and progress, no better-informed publication can be consulted.

The Coal and Iron Industry.

The determining factor in a nation's position in the world is held to depend ultimately upon the possession of coal and iron. In these essentials to a country's welfare, and its industrial potentialities, Canada is richly supplied. It is doubtful also whether there is any other country richer in gold and silver, in lead, copper, and nickel, and in the other principal metallic and non-metallic minerals, the fuller development of which must shortly command the attention of capital.

The present ascertained coal areas of the Dominion are estimated at 97,200 square miles. The chief deposits at present worked occur on the Atlantic coast in the province of Nova Scotia, the coal here being of an excellent coking variety.

Passing to the provinces of Ontario and Quebec, so far without any ascertained coal measures, and relying chiefly on the United States for mineral fuel, we may observe that this region is endowed with unlimited water-power capable of supplying direct mechanical or electrical energy for industrial purposes. In Western Canada, again, we have coal-beds ranging from lignite in Manitoba to semi-bituminous and anthracite towards the slope of the Rocky Mountains. In British Columbia immense bodies of bituminous coal in the south and east are being worked for the mining industries in the province and in the adjacent United States. On Vancouver Island is found the best coal yet discovered on the whole of the Pacific coast. The mines here are principally worked for export.

The iron ores of the Dominion, says Mr. Jeans, of the British Iron Trades Association, "are unquestionably of great extent and importance but just how much so no one at present can say, because the amount of exploration that has been undertaken is limited." In Nova

Scotia iron ore is found in workable amounts in most of the counties; for all practical purposes, however, the enormous ore reserves of Newfoundland — still politically outside the Dominion—must be included among Canadian sources of supply. The most notable are the hematite deposits on Bell Island estimated to contain 35,000,000 tons, the property of Nova Scotia ironmasters In Quebec extensive deposits of magnetic iron-sand exist on the north shore of the St. Lawrence river, where it is estimated that many millions of tons of ore containing a high percentage of iron, and practically free from phosphorous and sulphur, could be obtained by a good process of concentration. In Ontario the same authority states that "it is doubtful whether in any part of America so great an extent exists of rocks favourable for the occurrence of ore deposits as in Ontario. . . . Already a number of mines have been located both of hematite and of magnetite, and it need not be surprising if within the next five or six years mines are developed in northern and north-western Ontario." Exploration in the last-named district so far has given most satisfactory results, especially in the Lake Superior region. Here, in the Michipicoton district, and in the Antikokan ranges, important bodies of ore are being worked. Indications as tested by the diamond drill go far to establish the fact that the great iron ranges to the south and west of Lake Superior, whence the United States' iron industry derives to-day 70 per cent. of its raw material, extend across into Canada. The Chief Inspector of the Ontario Mining Bureau, speaking of the outlook for the ores of the province, states*—

"Of above 35,000,000 long tons of iron ore produced in the United States in 1902, some 27,500,000 came from the mines of the Lake Superior region, by far the largest quantity that has ever been raised there. Before these tremendous and increasing draughts even the large reserves still remaining will at no distant date disappear, and long before that time arrives the iron ores of Ontario will be in strong demand. All these deposits are tributary to the great lakes, and are carried, by the cheapest transportation known, to the points where they will be required."

Leaving Manitoba and the North-West Territory out of our calculations, we come finally to British Columbia, where ore deposits of high quality are known to exist, and have been located in large bodies within easy reach of ocean transportation. Considerable quantities of these ores are already being exported to the iron industry of the United States on the Pacific Coast in competition with native ores, despite the tariff of 40 cents. (1s. 8d.) a ton to which such importations are subject.

Canada's iron industry of to-day came into existence with the protectionist tariff of 1887. Its growth from that date has been continuous, and to-day there is a capital of 40,000,000 dols. invested in Canadian iron and steel works, and in the iron mines of the country. Successive Canadian administrations, convinced of the necessity of the industry to the national growth, have given additional encouragement in the form of bounties on the production of pig-iron and steel billets. The industry has now reached an advanced point in its formative stage, and may at any time assume the ultimate form of a great industry.

The present equipment of the Dominion consists of four coke and six charcoal smelting plants, with a total capacity of 1,000,000 tons of pig-iron per year, and of five large steel-making plants, capable of producing 500,000 tons of steel annually. The works are at Sydney, New Glasgow, Londonderry in Nova Scotia, Radnor in Quebec, and at Deseronto Hamilton, Midland, Collingwood, and Sault Ste. Marie in Ontario. Certain of these plants have had their vicissitudes, but all are now successfully adjusting their output to local needs. The annual consumption of iron and steel in Canada is estimated to-day at 850,000 tons, with every prospect of a rapid increase. Local production at present is equal to about one-third of the actual capacity of the works referred to, the balance of Canada's total requirements being imported, as to 70 per cent. from the United States, and as to 30 per cent. from the United Kingdom.

The decision of the Government in 1904 to put a protective duty on steel rails—hitherto on the free list—must lead eventually to the production within the Dominion of the greater part of its rail-requirements. These requirements, for the present mileage—20,000 miles —are estimated at 200,000 tons annually,* and with the new extensions in progress and planned, must increase rapidly. The only rail-mill in operation at present is at the Canadian "Soo," with a capacity of 500 tons a day; a second mill of 1,000 tons capacity will be completed in July next at Sydney in Cape Breton on tide water, where the largest

* Report of the Ontario Bureau of Mines, 1903. Toronto.

* "Road-making in Canada," in the *Engineer*, Sept. 30th, 1904.

and most ambitious Canadian iron and steel plant is situated. At this point the conditions of cheap production are admitted to be unequalled on the North American continent, perhaps in the world.* English expert opinion places the minimum average cost of producing pig-iron at Sydney at from 30s. to 35s. a ton:—

	s. d.		s. d.
Iron ores, including mixtures	15 0	to	17 0
Coke	10 0		12 0
Labour	2 0		3 0
Miscellaneous	2 0		3 0
	29 0		35 0
Bounty	12 6		12 6
Net figures	16 6		22 6

Sydney's advantage over Pittsburg, U.S.A., lies in the lower cost of assembling the raw materials for producing a ton of pig-iron. Again, for the export trade Sydney has an advantage over Pittsburg of 460 miles land-carriage to the sea-board, and of about 1,000 miles of ocean-carriage so far as the European market is concerned. These conditions should always prove a great factor in securing for Nova Scotia a pre-eminence in the production of iron and steel. The principal centres of consumption in Canada are in Ontario, and in this province the remaining iron and steel plants of the country are to be found, one of the first magnitude being, as stated, at Sault Ste. Marie. All these plants lie at, or near, lake navigation; they are designed to meet local requirements and the demands that may arise from new industries such as the construction of lake-shipping, which is now of immediate importance in view of the enormous tonnage which Western Canada is providing for transportation in Canadian bottoms to Canadian lake and ocean ports.

The day of the iron industry in British Columbia is not yet. However, the character of the development that lies before that province on the Pacific Ocean, its growing shipping interests, the exceptionally rich local iron and coal deposits, and the distance from the iron industry of Eastern Canada all suggest the probability of early action being taken.

Wood-Pulp Industry.

No country in the world has forest resources equal to those of the Dominion. From the earliest times to the present day the saw-mill interest has stood in the front rank of Canadian industries. Of late years the perfection of the processes for utilising wood in the manufacture of paper has increased many times the value of Canadian spruce forests, and has given Canada another primary industry of such far-reaching importance, in wood pulp and paper, that no apology is necessary for giving the wastes special attention. Sir W. White, in speaking of his recent visit, said*:—"Many opportunities were afforded us to see examples of the utilisation of water-power, and no one can fail to realise the enormous possibilities of development of the pulp and paper industry in Canada with cheap power and a supply of good labour." The province of Quebec has the greater number of the present mills, and together with Nova Scotia and New Brunswick is the natural seat for an industry whose market must lie largely outside the country. Water-power is obtainable almost everywhere; labour is cheap and abundant, and the cutting of pulp wood is easy and continuous throughout the year. An enormous supply of cheap raw material is thus available. Again, by providing settlers on new lands with a cash market for the wood they clear from their land, which was previously unsalable and, therefore, burnt, the pulp industry is a valuable agent in securing the settlement of new districts in Eastern Canada. Upwards of half-a-million cords of this pulp wood last year were carried by the railways across the frontier to paper mills in the United States, all of which might be worked up into pulp and paper in Canada itself were the requisite capital and enterprise forthcoming. Canadian pulp mills are planned for a large output with an eye, both for the home market and for export: some of the mills are devoted exclusively to the export trade, and these, for obvious reasons, are invariably located at or near tide water. The market for pulp is in the United States and England, and on the Continent, in Belgium and in France; the paper goes mainly to the United Kingdom. The tendency of the industry is to manufacture, the whole output of the ground or "mechanical" pulp into the finished article, and additions, therefore, of plant for producing chemical pulp are becoming general. Typical mills of the latter kind are the Laurentide Company, at Grand Mere, near Three Rivers, on the St. Lawrence, making 125 tons of paper and 50 tons of cardboard a day. The whole output is supplied to the United Kingdom.

* "Canada's Resources and Possibilities." London, 1904.

* *The Times*, January 11th, 1905.

The Belgo-Canadian Company, at Shawinigan Falls, in the same region, operated by Belgian capitalists, has an output of about 100 (dry) tons of pulp per day, the whole of which will be shortly turned out in the form of paper, for export. The Chicoutimi mills on the Saguenay river produce pulp only, at the rate of 100,000 tons a year, and this output is to be materially increased. English capital is engaged in this industry on the Miramichi, the St. John, and other rivers in New Brunswick and Nova Scotia. Paper manufacturers recognise that the control of supplies of cheap raw material is essential to the success of their mills in the future, and this fact must ensure the rapid growth of this industry in Canada. As an instance of intelligent anticipation of the future may here be mentioned the recent purchase by a leading London paper company of pulp wood properties and water power on the coast of British Columbia for the supply of their trade in Australia and Eastern Asia. The timber resources of British Columbia per square mile are even greater than those of Eastern Canada. The advantages of cheap power and of open navigation throughout the year will secure in due course for that province a leading position in the pulp and paper trade of the Pacific.

Canadian Water Power.

Probably Canada's greatest industrial asset and the best guarantee of her industrial future lies in her unequalled water-power scattered by the prodigal hand of Nature throughout her vast territory. An idea of the general distribution and of the volume of the power available in Eastern Canada may be gathered from the statement of the distinguised Canadian engineer, *Mr. Thomas C. Keefer, C.M.G., estimating Canada's share of the St. Lawrence basin water-power—between Lake Superior and Montreal—at no less than 10,000,000 horse-power. The value of Canada's water power has been immensely increased, says Mr. Keefer, by the introduction of electro-chemical and metallurgical industries, by the extension and expansion of the wood pulp industry for all of which the country possesses the raw material; and, further, by the success achieved in the transmission of electrical energy over long distances. High pressure currents of 50,000 volts have already been transmitted a distance of 200 miles. Lord Kelvin is reported to place the profitable limit at 300 miles. Thus the future industrial development of Canada will undoubtedly be closely associated with the utilisation of her water falls. It is chiefly, however, in connection with electro-chemical works that Canada may look immediately for the greatest return from water-power, as here it is a question in which intense electricity has a monopoly for the production of aluminium, calcium, carbide, carborundum, and other products, for the generation of which cheap and abundant water-power is indispensable.

* Presidential address, Royal Society of Canada, 1899.

The great future awaiting the electric furnace for the manufacture of iron and steel, phosphorus, &c., must also be borne in mind.

In mining, cheap electrical power is of the greatest value. Canada's great mineral wealth has hardly been touched; her mining districts have abundance of water-power available for electric haulage, pumping operations, air compressors for working drills, ventilation, and other purposes. Again in Eastern Canada new lines of railway and branch lines of existing systems might easily be worked independently by electrical power, thus hastening the settlement of the country and the establishment of industries in districts now difficult of access.

In these and other like directions the control of raw material in conjunction with unlimited electrical power, unrivalled transportation facilities, and a unique geographical position, should enable Canada to play a notable part in the world's industry, with which British capital might be profitably associated.

These possibilities flowing from the use of water-power are not merely in the air, but are now being realised in Canada on a large scale. Within a few months Winnipeg, with a population of 85,000, will obtain all the power required for lighting, heating, traction and manufacturing from a 40,000 horse-power installation on the Winnipeg river 60 miles away. At Port Arthur and Fort William, the Canadian wheat-shipping ports on Lake Superior, the water-power of the Kaministiquia river is being harnessed to supply 80,000 horse-power. At the Canadian "Soo" 60,000 horse-power is already available for local industries including chemical mills, wood pulp mills, reduction works, blast furnaces, and rail mills already established there, and for new industries. At Niagara Falls three Canadian companies are constructing works to develop 375,000 electrical horse-power, and further sites are available at the same spot for an additional 300,000 electrical

horse-power. At Ottawa the Chaudiere Falls, besides driving the largest lumber mills, supply electrical energy for lighting the city, for trams and local railways and various industries of the electro-chemical class. Within a few miles of Ottawa, at the Chats Falls, 200,000 horse-power are available, and within a radius of 45 miles a minimum of one million horse-power. Montreal already uses not only the electric power generated at the Lachine Rapids in the vicinity, and on the Richelieu river, 20 miles distant, but takes over 6,000 electric horse-power from the Shawinigan Falls on the St. Maurice river, 89 miles distant. At the last-named place there are hydraulic works completed for 100,000 electrical horse-power in an ideal industrial position.

Municipal Power Enterprise.

The Ontario Legislature recently conferred wide powers on municipalities to acquire or construct water-power works for lighting and heating and for supplying power for industrial purposes within their respective areas. This will show how greatly the development of local resources and of industries may be assisted in the future by expenditure undertaken by local authorities on power works. Toronto, with a population approaching 300,000, is officially identified with one of the Canadian power companies at Niagara, and expects to derive great advantages from the connection, as the city with all its lighting, railway, and manufacturing demands consumes some 30,000 horse-power annually.

As to relative cost a recent official enquiry establishes the average cost of steam power in Ontario at 35 dols. per horse-power per year, as against 15 dols. per electrical horse-power per year, the latter being the price paid to the Shawinigan Falls Power Company by the Corporation of Montreal. The report says:—

"This company has quite a costly development, and at the price stated pays interest on bonds and dividends on share capital. It may be assumed that municipal power developed under the most competent supervision and charged with a bond interest at a low rate, may be produced at a maximum cost of 15 dols. per electrical horse-power per year. If the consumption, then, of Ontario be tentatively taken at 150,000 horse-power, and the saving at 20 dols. per horse-power, the net *annual* saving to Ontario consumers of electric power developed and sold at cost is practically 3,000,000 dols. This sum capitalised at 4 per cent. represents a capital value of 75,000,000 dols. The actual money value to the consumer would be of course in excess of this owing to the cheapening of production and the stimulus to consumption that would result."

As one of the pioneer plants in Canada in the field of water-power development on a large scale for industrial purposes, the Shawinigan Falls Company call for more than passing notice, and the following particulars have been supplied by the courtesy of the company's secretary, Mr. Howard Murray. The enterprise is due to American brains and capital. The development made is capable of supplying 100,000 electrical horse-power, but extensions much in excess of that figure have been provided for. At present the company furnish over 6,000 horse-power to Montreal, 89 miles distant, and supply also a number of small centres with power for lighting and industrial purposes. At the Falls, a town of more than 4,000 inhabitants has sprung up, and here a number of industries are now established. Among these are the Northern Aluminium Company, owned in Pittsburg, U.S.A., making metallic aluminium by the Hall process. Since October, 1901, these works have produced aluminium continuously, the plant never having stopped its production for a single hour; a plant for making carbons for electrolitic purposes, and one for wire-drawing and cables; here were made the cables for the transmission lines to Montreal. The works use at present 5,000 electrical horse-power, but have arrangements to take up to 10,000 electrical horse-power as required. Another concern manufactures carbide, and has at present a capacity of 5,000 tons; power is supplied in the form of an alternating current of 25,000 volts. Further, a plant for producing ferro-manganese is also in operation, and a linen mill is projected.

The company supplies water direct to factories desiring to install their own water wheels; and of this class is the Belgo-Canadian Pulp and Paper Company, owned by Belgian capitalists and using 8,000 horse-power (mechanical power). As to the industries which would be offered particular facilities at Shawinigan Falls, the secretary writes—

"They would naturally come under the head of pulp and paper mills, electro-chemical industries, requiring large units of power, and in general manufacturing concerns, such as cotton mills, boot and shoe factories, which would obtain in this region, besides cheap power, labour at low rates—a great advantage in such industries. With regard to the cost of power, such figures might be quoted as from 5 to 6 dols. for

water-power (mechanical power) for use in pulp and paper mills, and from 12 to 15 dols. per horse-power for electric current."

The advantage of having at these various points an enormous supply of energy is almost incalculable; and the development of the great water-power companies which have been organised to make those natural resources available, is one of the most profitable and legitimate forms of employment for capital to be found in Canada.

Commission on Electric Smelting.

Impressed by the prospects awaiting the utilisation of electrical energy in the metallurgical industries the Canadian Government sent last summer a Commission to Europe to investigate, test and report on the different electro-thermic processes at present used in the smelting of iron and the making of steel.*

The conclusions arrived at are highly interesting and important, and go to show that in the present stage of development of the electric furnace pig-iron can be produced on a commercial scale at the same cost as in the modern blast furnace when electric energy is cheap and fuel dear, or on the basis taken in the report, of electrical energy at 10 dols. per horse-power per year, and coke at 7 dols. a ton. Under ordinary conditions where blast furnaces are an established industry electrical smelting cannot compete, but in special cases where ample water-power is available and blast furnace coke is not readily to be had, electric smelting may be commercially successful. Structural steel cannot at present be produced economically in the electric furnace in competition with Siemens or Bessemer steel, but such furnaces can be used commercially for the production of high-class steel at a considerably lower cost than by other methods. "Electrical smelting under its present development must be confined for the present chiefly to the manufacture of high-grade steel, and of the many ferro-compounds, such as ferro-manganese, ferro-silicon, &c. . . . . . that a possible field may be the utilisation of iron ores that carry such large amounts of the titanium group of elements as to require a greater heat than is usually permissible or obtainable in a blast furnace, and that the electric furnace may find a greater field of usefulness in this smelting of ore of the more costly metals, such as copper, nickel, &c."

* Report of the Canadian Commission on Electric Smelting, Ottawa, 1904; and *Iron and Coal Trades Review*, December 23, 1904.

Transportation.

Transportation, next to production, is the most important commercial question in a country of vast distances and low-priced products. In no country is inland transportation more economical than in Canada; and it is due to the vast system of inland navigation of the valley of the St. Lawrence and of the basin of the Great Lakes. Cheap water carriage in turn influences the charges for railway transport. In industrial Canada, therefore, we have added to cheap power the cheap assembling of raw materials for manufactures and the cheap distribution of the finished product, a combination of conditions not to be surpassed elsewhere. The tonnage moved annually on the great lakes is not less than 40,000,000 tons, carried chiefly by the United States' lake shipping, whose total tonnage aggregates 5,000,000 tons. During the last three years, however, the number of Canadian lake boats of the large type has greatly increased. At present steamers of 2,000-ton burden can pass freely from the Atlantic by the St. Lawrence river canals to the head of lake navigation—2,500 miles inland. But the bulk of the lake carrying trade is done by freight steamers of 5,000 to 8,000 tons burden, of 18 to 20 feet draught. These enormous vessels cannot go below Buffalo on Lake Erie, owing to the depth of the connecting canal navigation, viz., 14 feet, and the small dimensions of the locks. Further important developments, however, are promised in the near future by the construction of the Montreal-Ottawa and Georgian Bay Canal, affording a 20-foot navigation to the seaboard, entirely through Canadian territory, and permitting the passage of the largest freight steamers. Incidentally it will enable the present lake tonnage to be withdrawn during the winter for employment elsewhere; ocean steamers also of all but the largest size could pass, if desired, to and from lake ports. The trade in grain alone destined for export, *viâ* Atlantic ports, which is carried down the great lakes, is calculated to exceed 5,000,000 tons annually, of which 1,000,000 comes to Montreal. This new canal route to Montreal will offer a saving in distance of 450 miles, and of four days in time over the present longer water route. The saving in freight charges it is stated, will be so considerable—not less than one half the present rates — as to ultimately divert to Montreal the bulk of the export trade in grain and away from its present route *viâ* Buffalo and the Erie Canal and

railways to the American Atlantic seaboard. Moreover, the Georgian Bay Canal scheme would incidentally give Ontario a new front, and with the development of the important water powers occurring all along the line of the canal, create industrial opportunities second to none in Canada. The construction of this canal route is approved both by the Government and by the commercial community; it is now a moot point whether the Government will not itself undertake the building as a public work rather than allow the company holding the charter to carry it out as a private enterprise. In connection with the transportation problem, Mr. Keefer points out the importance of Canada's geographical position in relation to the commercial centre of gravity of the North American continent. This centre is very near Lake Erie. From the western end of this lake (Niagara Falls) the water route to the Atlantic, through the Straits of Belle Isle, follows the general direction of a great circle which cuts the commercial heart of Europe, and is, therefore, upon the shortest route or "air-line." As time goes on the whole of Canada must derive immense advantages from these unique transportation conditions, actual and prospective.

How to Influence Great Britain.

In the light of these potentialities now in course of realisation great things industrially may be expected in Canada during the next ten or fifteen years at most. A conservative estimate of the conditions of to-day would anticipate an even more rapid development in Canada than that which has characterised the United States in the past.

In Great Britain the greatness of Canada's destiny within the Empire finds daily fuller appreciation. The desire for closer communion and for more intimate knowledge has been seen of late years in the official visits of important British institutions and societies to Canada. The British Association has visited Canada twice, viz., Montreal in 1884, and Toronto in 1897, and has been followed by the British Medical Congress. In 1903 the Congress of the British Chambers of Commerce met in Montreal—a most notable meeting; and last year, the Institute of Civil Engineers went over with its President, Sir W. White.

Canada cannot have too many of these visits or see too much of the great captains of industry, and of the men of science from this side, or of English statesmen, such as Professor James Bryce, M.P., and Mr. John Morley, M.P., who have just returned. There are also the too-seldom tried expedients of trade missions, of visits of representatives of groups of industries and of financial interests to study Canada's markets, her fresh sources of raw material, and special undertakings to be developed by British capital and enterprise.

Imperial Commercial Service for Colonies.

In this connection the Imperial Government might be of great assistance. One suggestion I would make is that means be taken to perfect the colonial organisation of the new Commercial Intelligence Office of the Board of Trade, by creating a service of Commercial Agents to reside in the British possessions, these agents to report at frequent intervals through the Colonial Office to the Board of Trade on all matters concerning the resources, growth, local enterprises, public contracts, openings for trade, and the investments for capital, as is now done by H.M. consular officers and the special commercial *attachés* and commercial agents, in regard to foreign countries through the Foreign Office.

Foreign countries undoubtedly derive great and continuous benefit from the issue of these British consular reports and the work of these officials at the expense of the British taxpayer, whereas Canada and the British colonies receive no corresponding assistance whatever in making their claims known. Canada depends solely upon her own service of special agents in this and other countries. The suggested service of Imperial commercial agents to reside in Canada would go far to remedy this seeming neglect, and in any case the defect in the present system of collecting and distributing trade information, to the exclusion of the British colonies. It would materially assist colonial efforts at home and abroad in having their growth and their resources, agricultural and industrial, made known systematically through the Imperial channel.

I would advocate this Imperial commercial service in the Colonies no less in the interests of the trade of the United Kingdom. Manufacturers and merchants at home will remember that their colonial trade, on the *per capita* basis, is relatively more valuable to them than that with foreign countries. It is a trade, therefore, which political considerations and self-interest would see increased, and which should, therefore, have the solicitude

of the Government in providing aids to its development, not inferior to those given to the trade with foreign countries. This the commercial community here has a right to expect. Carefully selected representatives, with a knowledge of the needs and circumstances of the United Kingdom, would be able to select and present information in an acceptable manner, and from the English standpoint. Information supplied from a Canadian point of view, and with a Canadian bias, can never be as acceptable or as authoritative. It is, of course, not suggested that the proposed service should replace, but rather supplement the present commercial agents of the Canadian Government in the United Kingdom, who, while acting mainly in the interests of Canadian export trade to Great Britain, do not hesitate as far as possible to assist the trade of Great Britain with the Dominion.

Congress of British Chambers of Commerce, 1903.

It is also time that the Imperial Government should take some action on the important recommendatons of the British delegates to the Congress of the Chambers of Commerce in 1903, viz., to adapt the British newspaper postal rates to meet those of Canada, which the latter has already put into force with the Mother Country and with the United States—and this, both for commercial, as well as for political reasons; also to co-opererate in arranging greater efficiency in the direct postal service with Canada, and an improved direct British cable service—all suggestions of the greatest possible and immediate importance.

I fear I have wandered somewhat from my theme, but the special circumstances of Canada on the threshold of her new industrial development must be my claim for indulgence in having touched on matters which under other conditions might be considered not altogether relevant to the subject.

DISCUSSION.

Sir Westby Perceval (who took the chair on Lord Ridley leaving to fulfil another engagement) said he was extremely glad of the opportunity of thanking Mr. Just for his able, lucid, and instructive paper. He believed the general impression would be one of astonishment at the magnitude of Canadian manufactures. As had been truly said, every one recognised Canada as a wheat-growing country, and as having vast mineral resources, and great timber tracts, but possibly only a few appreciated sufficiently how very important her manufactures had become, and, what was perhaps more important, the vast field for development possessed by those manufactures. In one respect the paper seemed to afford an illustration of the way in which this country, whether in military warfare or industrial warfare, allowed the other side to get in the first blow. It was significant that the larger proportion of the capital being imported into Canada was not British but American. That was a matter for regret, as was also the fact that a large number of the immigrants into Canada were American or foreign, and not British. It did not matter so much to Canada, but it very much mattered to this country, and possibly to the Empire as a whole. It also occurred to him as somewhat noteworthy—though he did not wish to enlarge on the subject, as it was dangerous ground—that a country like Canada, with such enormous manufacturing capabilities should be the first country to offer Britain a trade preference. It seemed to him to indicate a spirit of self-sacrifice, which, if more widely spread, would certainly tend to remove one of the chief difficulties of bringing about a closer trade within the Empire. At the conclusion of the paper Mr. Just touched on a subject of very great importance, which the paper, when published, would be seen to develop, and he hoped some public notice would be taken of it, namely, that there should be some system for acquainting people of this country officially with commercial information regarding the colonies. Of course, the colonies endeavoured to do that for themselves. They had agents in this country who tried to educate the British public as to the opportunities presented by their respective colonies, but this was not the same thing as an imperial officer collecting and imparting that information, and responsible to the public for its accuracy. That point seemed to be well worthy of close examination, and he hoped that some practical outcome would result.

Mr. S. Charles Phillips said the people of England were always glad to hear of anything which might be for the benefit of the Empire, especially when it came from a gentleman so well informed as Mr. Just. Canada was a country which was going forward all the time, and no doubt she had felt, in years gone by, the lack of British capital. However, he was pleased to see that a better feeling now pervaded the British nation, and that the Englishman was getting to know Canada more as she actually was than as she had seemed to be in our imaginations, helped by the school books of the period. He had visited Canada many times, and was familiar with the country from the Atlantic to the Pacific. Many enterprises were now coming forward which, with the help of British capital, would make Canada shine still more resplendently in the eyes of the British people and the world in general. In the engineering industry, in which he was much interested, it was marvellous how Canada had

forged ahead, and she was beginning to make herself felt even on the other side of the St. Lawrence—*i.e.*, in the United States, of which she was becoming more independent every year. He could bear out all that Mr. Just had said about the magnificent engineering concerns in Eastern Canada, particularly those which had been established by the great Canadian railroads. He believed that in great measure those railroads were becoming quite independent of United States sources of supply. An important industry which had not, on account of the number of subjects to be dealt with, received its due share of attention, was the flour-milling industry, which affected us in this country so vitally, as we were not a self-supporting nation, although we might be "free-fooders" or any other kind of fooders. It was known that Lord Strathcona took a great interest in the matter, more particularly in the mills out West—"Lake of the Woods." It would be a very sorry day for England if the flour-milling industry of Canada were to decline. But there was no danger of that happening; in fact, everything seemed to show that the industry was still paramount, and that it was going to advance with the other large industries of the country. The wood-pulp interest was inseparably wrapped up with the growth of timber in Canada. Canada showed the greatest supply of timber which the civilised world had ever seen, and he believed that country should jealously guard it. English people had for many years felt the benefits of the timber industry from more than half-a-dozen points of view, including timber for furniture, for building, and of late years in providing the wood-pulp used in the composition of the daily newspaper. He was glad to say that millions of dollars were every year being put into the wood-pulp and paper industry of Canada, the chief market of which was this country. Had Canada not been encouraged to come forward and engage in that industry it would have been a bad thing for the British paper trade, as the competition of Norway and Sweden had to be considered in this respect. In fact, Canada had been the means of keeping prices of the raw material from undue inflation—the present prices, which had been forced up abnormally through lack of water supply in Scandinavia being excepted. A high price for paper would have prevented the launching and successful maintenance of the large newspaper ventures which the country had seen.

Mr. T. R. CLOUGHER was glad, from an educational standpoint, that such an admirable paper had been read. There was a vast amount of ignorance in this island about the colonies, and he wished to emphasize the great neceesity of giving Imperial information by Imperial agency. Mr. Just might make statements, and so might he (Mr. Clougher), but they might be regarded by the rather sceptical English public as biased. There might be some present that afternoon who thought the author might have been drawing the long bow; but, from a very long experience, he could endorse what Mr. Just had said. The field for investment was very great in Canada. He, however, differed from Mr. Just in what he said respecting Canada being a good country for the small investor. The proper thing for the small investor was to live in Canada for a couple of years, studying for himself the best point of location and the best advantage which could be offered by the country. He could not afford to gamble; the big investor could, because if he lost in one place he could make it up from another. The man who had two or three thousand pounds to invest must find out for himself where he was investing. People who knew the position he occupied, representing one of the great journals of Canada, were constantly asking his opinion upon such subjects, and he invariably advised them to go to Canada, leaving their money in England until they had learned how to safely invest it. It should not be invested in any concern because the High Commissioner's Department might have said it was good, but because the investor had found for *himself* that it was sound. Why was so little heard about the nickel industry of Canada? Because the chief nickel lands were in the townships of Dennison, Macgregor, and Drury, and held by people in Swansea whose interest it was to keep the knowledge of that interest from this country. The United States had their grip upon other sections, but someday England would wake up to the fact that one of the greatest assets owned by Canada was the undeveloped nickel industry, for nickel was one of the most important component parts of that nickel steel which this country required for its battleships. In the case of metal products, those who were endeavouring to bring about a corner, such as in the copper of the world, had to reckon with Canada before they could say whether the price should go up or down. He joined issue with Mr. Just when the latter said there were no coal deposits in Ontario. It was said at one time that there was no gold in Ontario, and he remembered listening to a discussion in which it was said there was no nickel to be found on the American continent. He hoped that when Mr. Just read his next paper he would be able to say, not only that Ontario had all those beautiful things he had referred to, but that it had coal and iron in the north shores of Lake Ontario.

Mr. J. COLEY-BROMFIELD said he was a recent visitor to Canada, having been commissioned by a syndicate of capitalists to proceed there for the purpose of ascertaining the truth about the capabilities and opportunities for investment. He had in his possession papers which confirmed all that Mr. Just had said. He had read in Toronto papers:—"We do not want artisans and mechanics here; why do they send men from England when our men can do the work?" But that was simply the trade union idea, it being thought that the more Englishmen were brought over the less would be the chance of

Canadians having good wages. His opinion was that nothing could be done in the present day that would at all reduce the earning power of Canada. Canada's opportunities were enormous. There would be no unemployed in this country if the British Government would do its duty to the colonies, and carry out the plan of establishing an Imperial bureau, so as to let it be known where our people could go with the certainty of obtaining employment and receiving good wages.

Mr. CLAYTON BEADLE said he had had the opportunity of visiting Canada recently, more particularly in connection with two great industries which would undoubtedly hold a very important position in the near future—those of cement and paper. With regard to cement, he accompanied the chairman of a very large company in this country to investigate the condition of the industry in the United States and Canada. It was clear to them that Canada was pursuing the same progressive course as was the United States, and putting down the best machinery. The quality of the article, he thought, would compare with that in any part of the world. With regard to the great paper-making industry, the resources of Canada were almost inconceivable, not only as to the available supplies of timber, but also as to the quality of it available for that purpose. It was generally believed that timber, to be suitable for the manufacture of paper, must not exceed a certain diameter. He went to British Columbia and made enquiries about the supplies of balsam, spruce, and hemlock, three timbers which undoubtedly made excellent pulp for paper. Those were very abundant on the Pacific Coast, and timbers from them had been sent to him from British Columbia between six and seven feet in circumference. Most pulp makers laughed at the idea of making pulp from such large timbers. But, by means of the sulphide process, he had succeeded in producing from each of those timbers pulp equal in quality to that imported into this country from elsewhere. It was difficult to account for such large trees yielding such excellent pulp, but he thought it had something to do with the fact that on the British Columbian coast there was a stream from Japan which kept the coast open throughout the whole of the year, so that it was not subject to the same extremes of heat and cold as was the Eastern Coast. He thought it was not generally known that those large trees were available for the sulphide process, and it was only a few months ago that he had the opportunity of investigating the matter.

Mr. JUST, in reply, said unless he found geological data that the rocks of Ontario contained coal he feared he must say coal did not exist there. He had been much interested to hear the comments of Mr. Clayton Beadle on the superior character of the wood-pulp produced in British Columbia by the sulphide process.

On the motion of the CHAIRMAN, a vote of thanks was passed to Mr. Just for his valuable paper.

FOURTEENTH ORDINARY MEETING.

Wednesday, March 15, 1905; SIR GEORGE BIRDWOOD, K.C.I.E., C.S.I., LL.D., M.D.; Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Carley, Geo. C., 14, Dingwall-road, Croydon.
Cuff, Herbert Mackenzie, E.Ex. A. and C. Telegraph Company, Singapore.
Davies, John Samuel, 9, Clifton-road, Newport, Monmouth.
Dowson, Ernest Alfred, 45, Newhall-street, Birmingham.
Flood, W. H., 1, Northbrook-road, Ilford, Essex.
Parrott, Lieut.-Col. Thomas Samuel, Exploration-buildings, Johannesburg, Transvaal, South Africa.
Prain, Robert P. F., M.Inst.M.M., care of Messrs. Jackson Brothers, Iquique, Chili, South America.
Sabnis, Rao Bahadur Raghunath Vyankaji, Kolhapur, Bombay, India.
Sparks, Hubert Conrad, Suffolk-house, Putney-hill, S.W.
Staver, William H., Casilla 336, Guayaquil, Ecuador, South America.
Thompson, Henry Yates, J.P., F.S.A., 19, Portman-square, W.

The following candidates were ballotted for and duly elected members of the Society.—

Aldwyncle, H. J., P.O. Box 5596, Howard-buildings, Johannesburg, Transvaal, South Africa.
Biliotti, Frank, 8, John-street, Adelphi, W.C.
Bracher, Mrs. L. E., Hamilton, Waikato, New Zealand.
Cooper, William James, A.M.I.Mech.E., A.M.I.E.E., 15A, Turnpike-lane, Hornsey, N.
Crawford, William, J.P., Mount Randal, Belfast, Ireland.
Dawson, David Stewart, 20, Hatton-garden, E.C., and Hotel Cecil, Strand, W.C.
De Landero, Carlos F., Apartado 3, Pachuca, Mexico.
Denny, Harry S., P.O. Box 4181, Johannesburg, Transvaal, South Africa.
Fawcett, Francis Thomas, 135, Nag's Head-road, Ponder's End, Middlesex.
Flannery, Sir J. Fortescue, Bart., M.P., 9, Fenchurch-street, E.C.
Hadaway, William Snelling, Penrhyn-cottage, Bushey, Herts.
Hughes, F. G., Salisbury, Rhodesia, South Africa.
Hutson, Alfred Robert, 123, Darnley-road, Gravesend.
Mitchell, W. F., 26, Craven-hill-gardens, W.
Samuel, S., 11, Portland-place, W.
Smith, W. Ramsay, D.Sc., M.B., Winchester-street, East Adelaide, South Australia.
Sumner, Orlando, Dalry-house, Ashton-on-Ribble, Lancs.

The CHAIRMAN, in introducing the reader of the paper, said he was known to many present as having served with great distinction as bacteriologist and chemical analyst to the Government of the Central Provinces in India; he was particularly selected for the appointment on account of his great distinction at Cambridge in the study of natural science, and in the performance of his highly responsible duties in India he had given the most complete satisfaction. His headquarters were at Agra, where he had all sorts of temptations to study the various artistic beauties of India. He had particularly devoted himself to the subject of the paper, and the discovery which he had to describe was one of very great interest, both practical and theoretical.

The paper read was—

ON SOME DISCOVERIES OF THE METHODS OF DESIGN EMPLOYED IN MOHAMMEDAN ART.

By E. H. HANKIN, M.A.

(Late Fellow of St, John's College, Cambridge, Fellow of Allahabad University.)

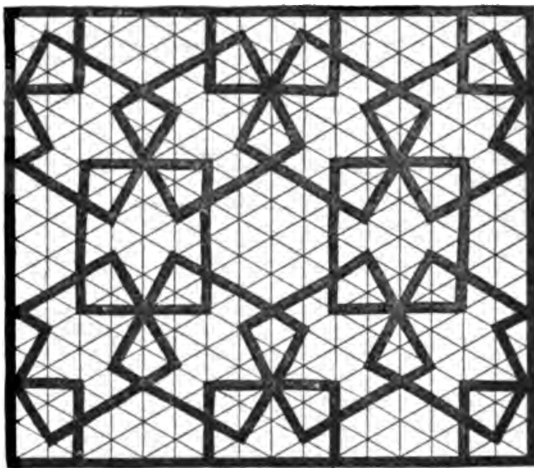
The most striking peculiarity of Mohammedan or Saracenic art is the employment of extremely complicated geometrical patterns. The actual methods by which these patterns were drawn and designed, are, so far as I am aware, unknown to modern artists, either in Europe, in India, or in Egypt. The works of Prisse D'Avesnes, of Bourgoin, or of Gayet, dealing with Arabian art, are equally destitute of any satisfactory explanation of the matter. Some years ago I commenced to study the subject in India. At length, by a lucky chance, I discovered a clue in a small room in one of the palaces of Akbar, the great Mogul Emperor. Here, nearly hidden by dust and dirt, I found the actual construction lines used by the artist some four and a-half centuries ago in producing an arabesque pattern. By means of the clue thus obtained, it became easy to draw the more complicated of the patterns. The clues to the simpler classes of patterns were obtained for the most part by observation and measurement.

The methods that I have to describe to-night, are not simply methods of draughtsmanship. They may be described as methods of design, as by their means it is possible and easy, not only to copy old patterns, but also to design new ones in conformity with the rules of geometrical art.

It may be advisable to explain that the patterns themselves, as I shall exhibit them to you thrown on the screen as black lines on a white ground, are not necessarily or essentially beautiful. They are merely skeletons of beautiful objects. An artist's skill is required to clothe with flesh, the dry bones of geometric design to produce from them artistic creations that impress the feelings and that exist as living triumphs of Saracenic art in the frescoes and tiled dadoes of the Alhambra, in the mosaics, pulpits, and mosques, of Cairo, and in the deserted palaces of Akbar at Futteypur-Sikri.

Geometrical patterns may be divided into the following four classes—(1) square, (2) hexagonal, (3) octagonal, and (4) arabesques.

FIG. 1.



HEXAGONAL PATTERN FROM HAKIM'S BATH AT FUTTEYPUR-SIKRI.

In the first class the space to be decorated is divided into squares. Parts of these squares go to form the pattern. This class will be found described in any elementary text-book of design, and includes various chequers, the fylfots, the Greek frett, rectangular lattices, &c.

The method of drawing the second class of patterns, the hexagonal, is also widely known and calls for no special description. Lines are drawn crossing each other, not at right angles, as in the square patterns, but at angles of sixty degrees, thus dividing the space to be decorated into equilateral triangles. An example of this pattern is given in Fig. 1, which represents a design found carved in plaster in the Doctor's Turkish Bath at Futteypur-Sikri. In this case some only of the pattern lines are identical with the construction lines. Others of the lines of the pattern are drawn crossing

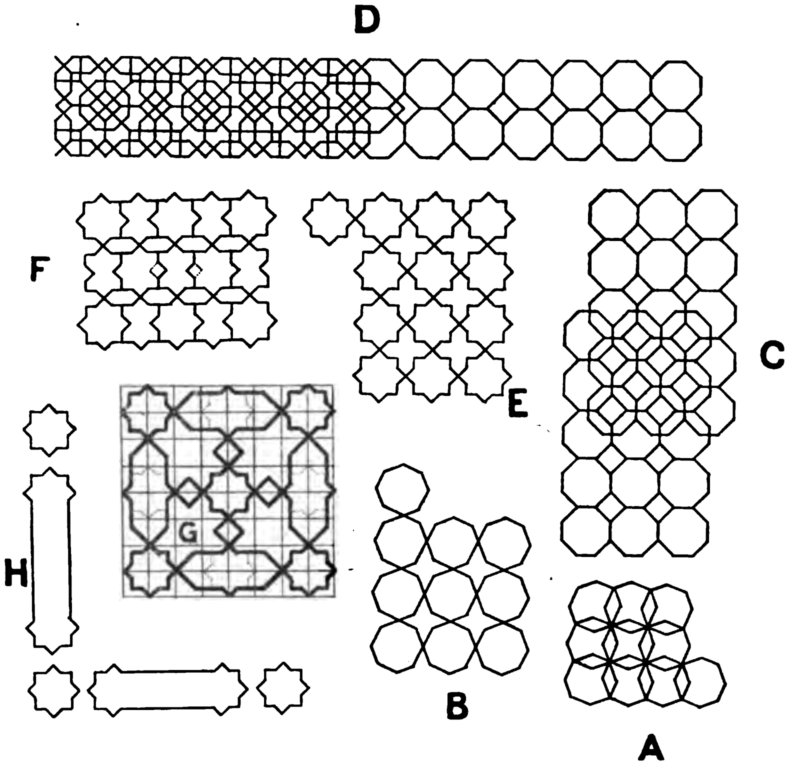
the construction triangles from one apex to another.

The third class of patterns consists of, or is derived from, octagons. Simple examples of this class are shown in Fig 2, at A, B, C, and D. Of these A, B, and C may be found used in stone pavements in the garden of the Taj at Agra. D is frequently employed for the perforated stone balustrades on buildings in the Taj Garden. I have grounds for believing that in drawing octagonal patterns an octagon was

Indeed it is difficult to see how the more complicated of the octagonal patterns could have been designed without the use of templates.

The complicated octagonal patterns usually contain octagons of two sizes, which, so far as my experience goes, may always be regarded as derived one from the other by the following very simple construction. In Fig. 3 an octagon is drawn in which opposite angles are shown joined in pairs by lines such as A B, and C D. The result of drawing these lines is to leave an eight-

FIG. 2.



EXAMPLES OF OCTAGONAL PATTERNS.

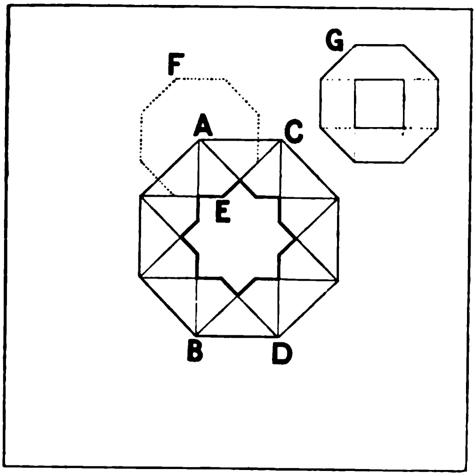
cut out of talc, or paper, or some other suitable material, and used as a template. In the case of Fig. 2, D, the octagons shown on the right of the figure are so accurately drawn (as a rule) as to suggest the use of a template, while the remaining lines are so inaccurately drawn as to suggest that they were filled in by hand. Whether or not a draughtsman should use templates in the actual employment of these patterns may be described as a matter of individual taste and habit. But that templates are useful in the designing of these patterns will be admitted on consideration of the facts contained in the following paragraphs.

pointed star (shown by thicker lines) in the centre of the octagon. Taking the point A as centre describe another octagon (shown by dotted lines) of such a size that one of its angles fits into the angle E of the eight-pointed star. This octagon is shown drawn separately at G. Thus we have a large octagon, a small octagon, and an eight-pointed star. These three figures combined in different ways go to form the majority of octagonal patterns. For drawing the patterns it will be found convenient to cut out these three outlines as templates.

The method of construction of a pattern of this nature is shown in Fig. 4. The large

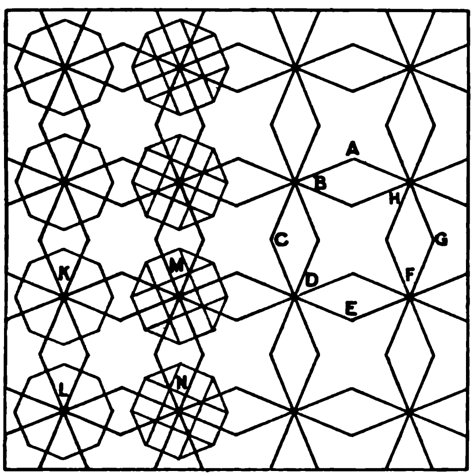
octagon template is first employed to cover the ground with large octagons overlapping by two of their sides, as shown on the right-hand side of the figure. For the sake of clearness the letters A, B, C, D, E, F, G and H, have been inserted to indicate the extent of one of these octagons. The small octagon template must now be used. By its means small octagons

FIG. 3.



DERIVATION OF SMALL OCTAGON FROM LARGE OCTAGON; ALSO OF EIGHT-POINTED STAR. These three figures form the basis of most octagonal patterns.

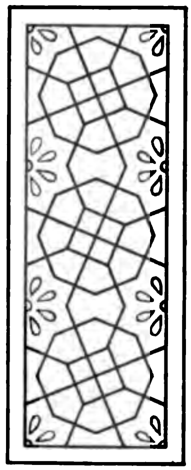
FIG. 4.



CONSTRUCTION OF PATTERN SHOWN IN FIG. 5. The ground is covered with large octagons overlapping by two sides. The letters A to E indicate the outline of one of these octagons. Small octagons, as at K, L, M, N, are drawn round alternate angles of the large octagons.

are drawn whose centres coincide with alternate angles of the large octagon, as shown on the left-hand side of the figure. But this does not produce a graceful pattern. The numerous lines crossing at a point, as occurs at K and at L, like the spokes of a cart-wheel, do not form a pleasing feature. Nor is the case much altered for the better when a square is drawn in the small octagon, as shown at M and N. But when certain of the lines are omitted, as illustrated in Fig. 5, we have a pattern of remarkable gracefulness in spite of its apparent simplicity. This pattern occurs carved in low relief in a panel of red sandstone in Birbul's House, Futteypur-Sikri.

FIG. 5.



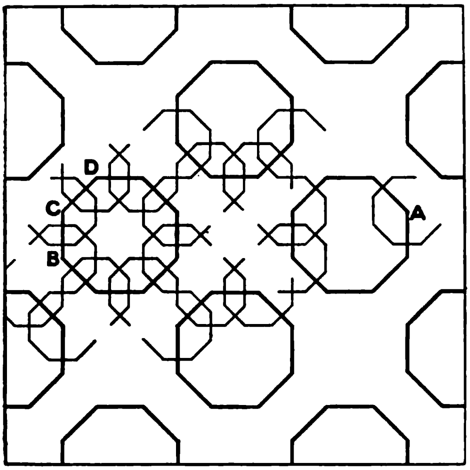
PATTERN FROM A PILASTER IN BIRBUL'S HOUSE, FUTTEYPUR-SIKRI.

It may be asserted that in this pattern the size of the octagon is well proportioned to the size of the panel, and the size of the square to that of the octagon. It is difficult to imagine that this result would have been obtained so successfully had the design been formed without the help of a rational geometrical method.

The construction of another octagonal pattern is shown in Fig. 6. In this case the large octagons are drawn, not in contact, but at some distance from each other. The distance is such that the space between any four adjacent octagons could just be filled by another large octagon. The small octagon template is now brought into use. As shown on the right-hand side of the figure, it is placed with its centre coinciding with the angle of a large octagon. Six sides of the small octagon are drawn in. The operation is repeated round

each of the other angles of the large octagon. Thereby the eight-pointed star is found to have been described in the large octagon. The other large octagons are similarly treated. A few other lines are required to complete the pattern. These are so simply placed as to

FIG. 6.



CONSTRUCTION OF OCTAGONAL PATTERN SHOWN COMPLETE IN FIG. 7. As shown at A, six sides of a small octagon are drawn round the angle of a large octagon. This is repeated round all the other angles (as B, C, D) of the large octagons. The few lines required to complete the pattern may be found by inspection of Fig. 7.

FIG. 7.

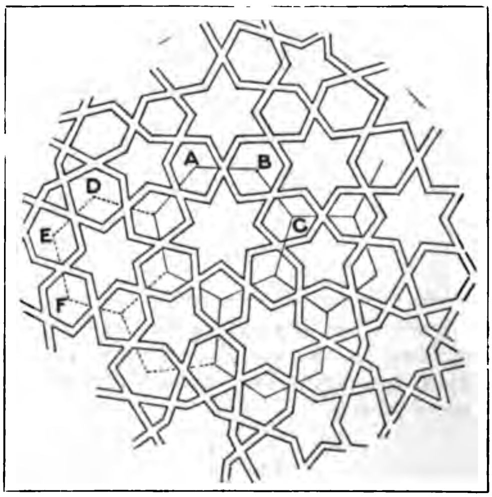
OCTAGONAL PATTERN OCCURRING IN INLAID MARBLE IN THE TOMB OF ITIMAD-UD-DAULA AT AGRA.

require no explanation. The completed design is shown in Fig. 7. It occurs in inlaid marble in the tomb of Itimad Ud Daula at Agra.

The eight-pointed star alone, without the help of any octagons, may also be used to form patterns. Examples of this are shown at E, F, G, and H in Fig. 2. In E eight-pointed stars are placed in contact. This is the pattern of the pavement of the interior of the Taj. F is the basis of a pattern that occurs in a dado in the vestibule of Akbar's tomb at Sekundra. In this case some of the eight-pointed stars are drawn complete. Others are overlapped by their neighbours. Pattern G is obviously formed from eight-pointed stars. A very beautiful example of the use of this pattern will be found in the work of Owen Jones on the Alhambra. H is a common border pattern formed from eight-pointed stars.

We now have to consider the most complicated class of patterns to which the term "arabesque" may be appropriately reserved, as these patterns are practically peculiar to

FIG. 8.



DIAGRAMMATIC SKETCH OF PART OF PATTERN OF A DOME IN THE TURKISK BATH IN THE JODH BAI'S PALACE AT FUTTEYPUR-SIKRI. The lines A, B, C are some of the original construction lines by means of which the pattern was drawn. Examples of the use of this clue are given in the following figures.

Mohammedan art, and both in their complexity and in their æsthetic effect stand on a higher plane than the patterns hitherto considered.

In most square, hexagonal, and octagonal patterns, the pattern lines run in two, three, or four directions respectively. In arabesque patterns the lines run in a much larger number of directions, suggesting that some unusual method was employed in their construction.

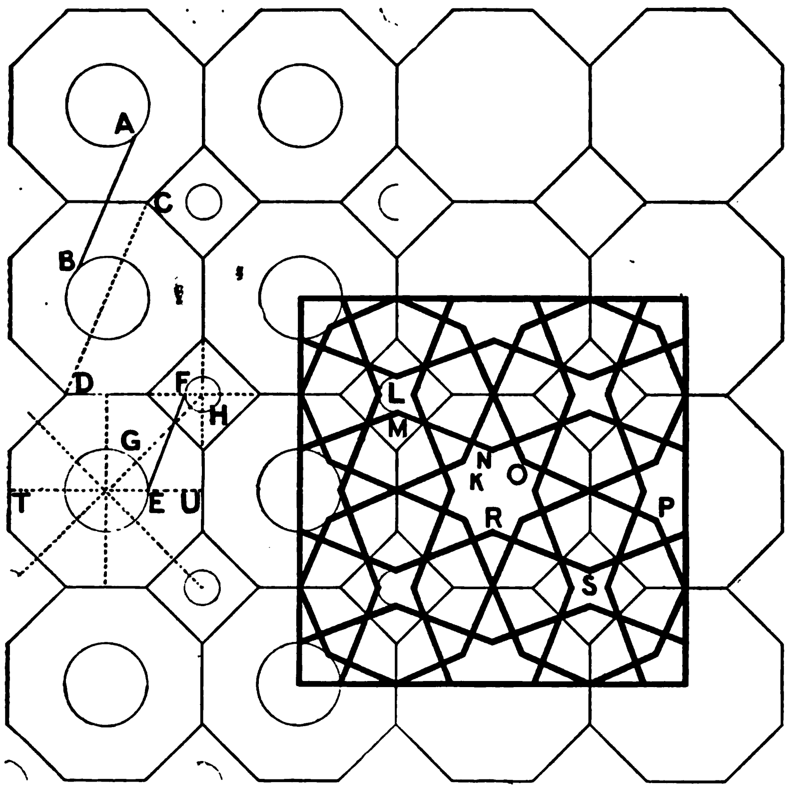
In Fig. 8 is represented diagrammatically part of an arabesque pattern that occurs in a dome in the Turkish bath attached to the Jodh Bai Palace, Futteypur-Sikri. It was this pattern that furnished the clue to the method of construction of arabesque designs. Besides

the thick pattern lines incised in the plaster covering the interior of the dome, I noticed some faint scratches indicated by the lines A B, and B C. On closer examination, I found that these scratches were parts of polygons, that if completed as shown at D, E, F, would surround the five, six, seven, and eight-rayed stars of which the pattern was composed. It at once occurred to me that these polygons were the construction lines used in producing the pattern. It was obvious that polygons in contact were easy to draw. Having drawn them, pairs of lines had to be drawn passing through the centres of each of the sides of the polygons. These pairs of lines crossed the side of the polygon, at nearly the same angle in each case. Each line was prolonged until it met a similar line that had crossed the centre of another side of a polygon. When this had been done all over the surface that had to be decorated, nothing more remained to be done, for the pattern was completed.

A few examples will show how simple is the method here indicated for drawing and designing of arabesque patterns.

In Fig. 9 the space is first covered with octagons in contact, which may be easily drawn by means of an octagon template. The resulting lines may be called the primary construction lines. Two pattern lines have to be drawn through the centres of each of the primary construction lines. The first question is at what angle or in what direction they are to be drawn? Within certain limits the exact angle does not matter provided this angle is the same in all cases. But the best result is obtained if each pattern line is drawn parallel to a diagonal of an octagon. For instance, the pattern line A B is drawn parallel to the diagonal C D. But in practice it will be found easier to draw lines such as T U which pass through the centre of the octagon and join the centres of its opposite sides. A pattern line is then drawn such as E F. This of course is drawn parallel

FIG. 9.

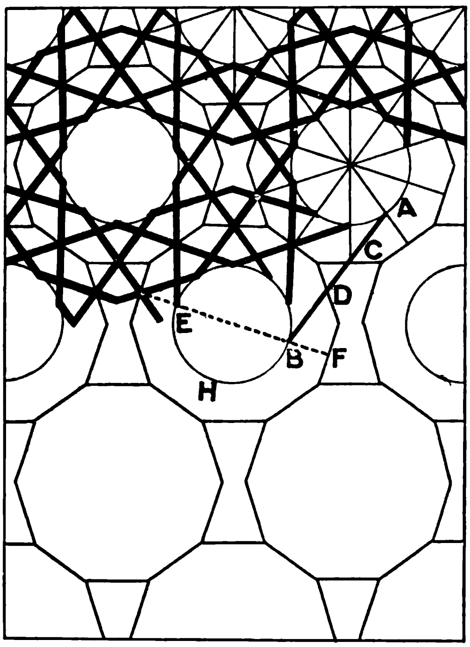


METHOD OF CONSTRUCTION OF A SIMPLE ARABESQUE PATTERN. The ground is first covered with octagons in contact. To form the pattern two lines have to be drawn through each centre of each side of the octagons.

to the neighbouring diagonal of the octagon. It cuts T U in the point E. From the centre of the octagon describe a circle G which passes through the point E. All other pattern lines pass from points similar to E on the circumference of the circle. A guiding circle may similarly be drawn in the squares, as shown at H. These circles and interradii form the secondary construction lines.

In the portion of the pattern shown completed, it may be noticed that the pattern line

FIG. 10.

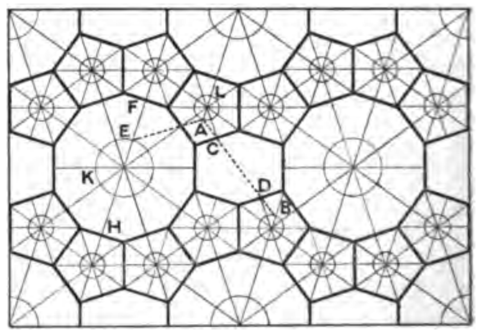


ARABESQUE BASED ON DECAGONS IN CONTACT. Two lines are drawn passing through the centre of each side of the decagon. Each of these lines is continued until it meets another similar line, thus completing the pattern.

M N is nearly but not quite in a straight line with the pattern line O P. This line O P is nearly but not quite parallel to the pattern line R S. A draughtsman not knowing the method now described would probably have drawn M N and O P in a straight line with one another. He would also probably have made O P and R S exactly parallel. So doing would have given the pattern an appearance of stiffness which is avoided by the present method of construction. This pattern is one of the commonest of arabesque designs.

Another arabesque V is shown in Fig. 10. Here the primary construction lines are decagons in contact. As before, two pattern lines have to be drawn through the centres of each of the primary construction lines, and it is necessary to commence by finding out the direction in which these lines have to be drawn. C and D are centres of construction lines. A pattern line A B must be drawn through these two points. This pattern line is continued until it meets an interradius of the decagon at B. From the centre of the decagon a circle H is described that cuts B. Other pattern lines meet this circle at places where it cuts the interradii. This is the most frequent method of finding the position of the secondary construction lines.

FIG. 11.



CONSTRUCTION OF ARABESQUE BASED ON DECAGONS AND PENTAGONS IN CONTACT. The first pattern line is drawn through centres C and D till it meets a radius of the pentagon at A. The second pattern line is drawn from A through the centre of the side of the pentagon, till it meets an interradius of the decagon at E. These two pattern lines give the size of the circles K and L. All remaining pattern lines pass in pairs through centres of sides of a polygon until they reach a circle. The completed pattern is shown in Fig. 12.

In this pattern each decagon of the construction line leads to a ten-pointed star of the pattern surrounded by pentagons. These pentagons are regular if the pattern has been correctly drawn. Other similar arabesques exist in which the primary construction lines are dodecagons and octagons, or dodecagons combined with regular nine-sided polygons. In these cases the resulting star-shaped spaces in the pattern are twelve, eight, and nine pointed, as the case may be, and the pentagons are not completely symmetrical.

We now pass on to consider an arabesque of a slightly higher degree of complexity. In Fig. 11 its primary construction lines are drawn as thick lines, and its secondary con-

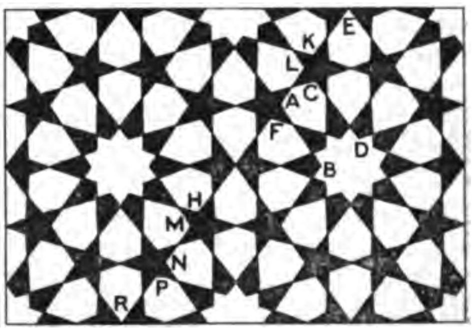
struction lines are drawn thin. The primary construction lines consist of regular decagons, regular pentagons, and irregular hexagons. The templates for this pattern consist of a decagon and a pentagon. Or more conveniently a decagon may be drawn with a pentagon attached to each of eight of its sides. This may be cut out of paper as one template. Such points as are required that are not on its periphery may be pricked through on to the drawing paper by means of a fine needle. The irregular hexagon requires no template. It is merely the space left where there is no room for pentagons.

In this pattern the secondary construction lines are found by the following easy method. The first pattern line A B is drawn through the centres of two construction lines at C and D. It is continued till it meets radii of the pentagons at each end, as at A and B. A circle L is described in the pentagon cutting the point A. A second pattern line A E is now drawn. This starts from the point A and passes through the centre of the side of the pentagon. It is continued until it meets the interradius F H of the decagon in the point E. A circle K is now drawn in the decagon that cuts E. All the pattern lines have to be drawn starting from analogous points on the circles K and L, or from similar circles drawn in the other polygons.

The completed pattern is shown in Fig 12. For the sake of making the pattern easier to comprehend, alternate spaces are tinted, as might be the case if it was used in a mosaic pavement. It is well to notice that, as here drawn, the lines E K, L A, F H, M N, and P R, are not quite in a straight line with one another. An artist not knowing the correct method of drawing the pattern would, with little doubt, have made of these lines a hard straight line running through the design, like a line in the pattern of a cane-bottomed chair. He would have added to this resulting and unnecessary stiffness, by making the rays of the ten-pointed star of parallel lines, which is equally a mistake, for A B and C D are nearly but not quite parallel.

A still more complicated pattern is shown in Fig. 13. Though the effect of the pattern, as here drawn, is surprising rather than pleasing, in the original, as it exists in a dado of coloured tiles in the Alhambra, it is a very beautiful object. An illustration of it may be found in the work of Owen Jones on the Alhambra. My drawing only represents a quarter of the panel, the point A being the centre. The method of construction though tedious is by no means difficult. Round the centre A describe a dodecagon, of which one quarter is shown at E F H. Touching this dodecagon at the point F, another dodecagon of the same size has to be drawn. It is lettered F K L Y and shown drawn round the centre N. Touching the dodecagon round N at the point Y is drawn a third similar dodecagon, whose centre is at O. Touching this latter at Z is drawn a fourth dodecagon whose centre is at R. Inside each of these large dodecagons are to be drawn smaller dodecagons. Their size is found as follows:—Join E K. On a radius of dodecagon A mark off E B equal to E K.

FIG. 12.



ARABESQUE BASED ON DECAGONS AND PENTAGONS IN CONTACT. Notice the lines A B and C D, and similarly placed pairs of lines, are not quite parallel. If they had been drawn parallel, the pattern would have been more stiff and less yleasing. The lines E K, L A, F H, M N, P R, are nearly, but not quite, in the same straight line with one another. This also prevents stiffness, and supplies an additional proof ot the advantage of the method ot construction explained in this paper.

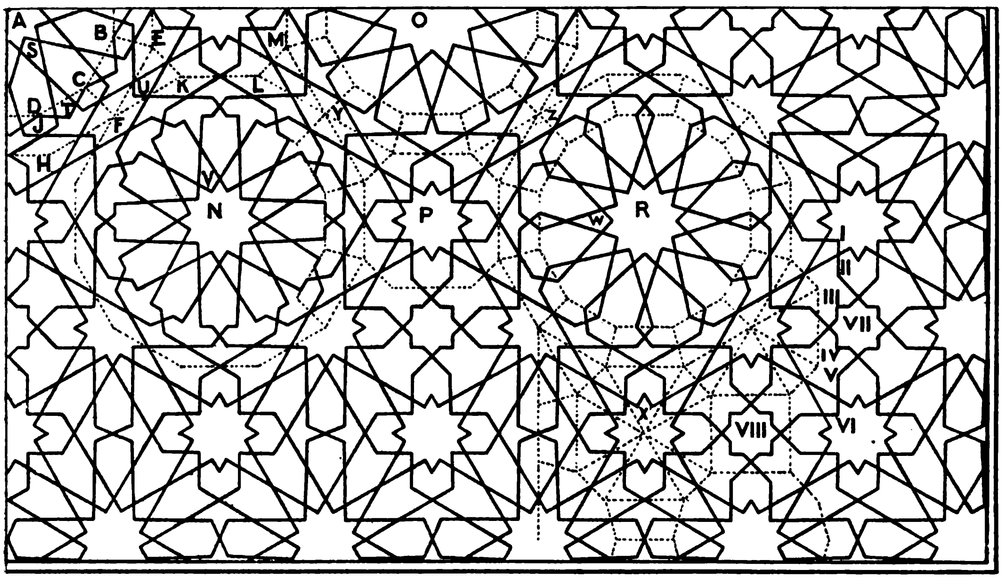
Then A B is the radius of the small dodecagon required. This is shown drawn and lettered B C D in dodecagon A. A similar small dodecagon has to be drawn in each of the other large dodecagons. A remaining feature of the primary construction lines is seen as an irregular octagon at P. This is merely the space left between the four large dodecagons A, N, O, and the fellow of N, which would have been drawn had the adjoining quarter of the panel been represented. Half of this irregular octagon is shown at E K L M. This space is repeated at P, and elsewhere in the pattern. The radii of this octagon must be drawn in as shown at X. No further description is needed of the primary construction lines.

The secondary construction lines are very simple. As may be seen by inspection, a number of the pattern lines are drawn, simply passing through the centres of two or more construction lines without any further guidance being required. In dodecagon O is drawn a twelve-pointed start of normal type. The twelve-pointed stars drawn round A, N and R are modified to give further variety to the pattern. It may be well to state that in solving the method of construction of this pattern, I had at my disposal only a very rough tracing of the not altogether accurate drawing in the work of Owen Jones. Consequently I had to rely to some extent on my general knowledge pointed star similar to those present in other parts of the design.

At VII and VIII (in Fig. 13) an eight-pointed star is shown. The primary construction outline for this star is a square, shown round VIII. The exact size of the eight-pointed star is a matter of taste. I have drawn it in such a way that the pattern lines I, II, III-IV, V-VI, are all in a straight line with one another. The original drawing is not sufficiently accurate to determine this point.

In Fig. 14 is represented a panel from the side of a stone pulpit in Cairo, copied (with some modification) from Stanley Lane Pool's work on Saracenic art.

FIG. 13.



METHOD OF CONSTRUCTION OF AN ARABESQUE BASED ON DODECAGONS, FOUR-SIDED FIGURES AND TRIANGLES. From a tiled dado in the Alhambra. One quarter only of the repeat is shown.

of the subject. The twelve-pointed star drawn round A has been made of such a size that the spaces S and T are equal to each other, and also equal to the space U. The space J is made as far as possible symmetrical. The twelve-pointed star drawn round N is made of such a size, that the space V is equal to U. A similar consideration governed the size of the space N in the star drawn round R. The irregular octagon P is adapted to produce an irregular eight-pointed star. This would be a blemish in the pattern. Consequently alternate points have been thrown back, as shown at X, which has been done in such a way as to produce a symmetrical twelve-

For drawing this pattern two templates are required. One is a regular sixteen-sided polygon. The other is a regular heptagon, the length of whose side is the same as the length of the side of the sixteen-sided polygon. Perhaps for convenience of description I may be allowed to refer to the latter as the "16-gon."

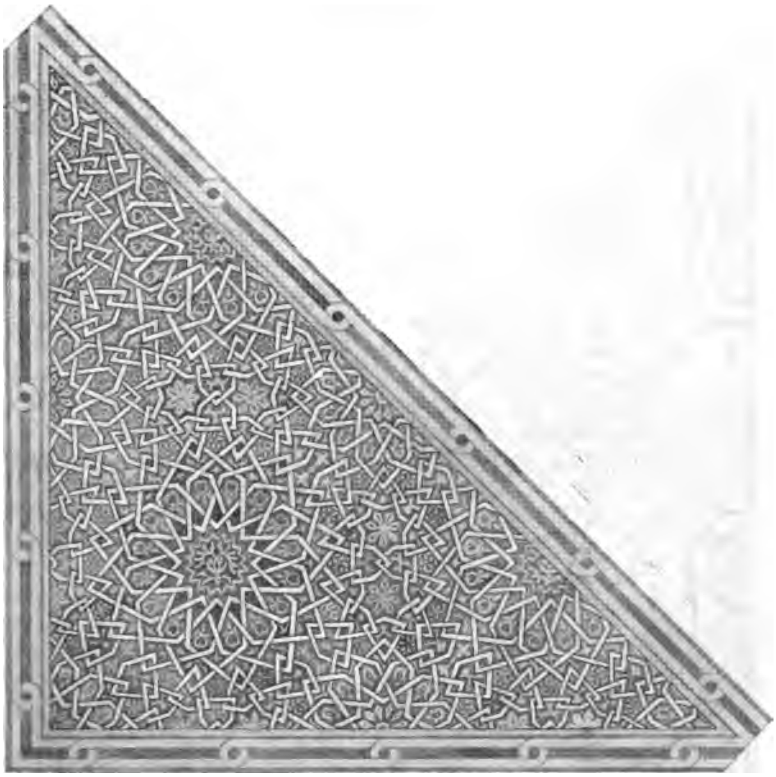
With the 16-gon template draw the outline B shown in Fig. 15. Place the heptagon template with one side touching B at K H. By this means draw in the heptagon D E F G H K L. Two sides of this heptagon, F G and G H, are indicated merely as dotted lines as they are not further required. The centre of this heptagon is at N. A second similarly situated

heptagon is now drawn in having its centre at P. The 16-gon template is now placed touching the sides E F O of the twinned heptagons, and a 16-gon is thereby drawn shown at A. Twinned heptagons are similarly drawn at symmetrical intervals round the original 16-gon B, and on one side the twinned heptagons indicate the position of another 16-gon which is shown in the figure drawn round C.

one of its sides touches, or is the same as, the side of its fellow.

The primary construction lines have now been completed. The secondary construction lines consist of the radii of the different polygons, and of one or two circles drawn in each of the polygons. Within limits the exact sizes of these circles do not matter. By trial and error a suitable size can easily be found.

FIG. 14.



PATTERN FROM PANEL OF A FOURTEENTH CENTURY STONE PULPIT IN CAIRO.
(Modified from Stanley Lane Poole.)

Between the 16-gons A, B, and C, is left a space which is filled up by a dodecagon R. Similar spaces are filled up by similar dodecagons at S and I, and also (partly drawn) at the three corners of the panel. These dodecagons are not quite symmetrical, but must be drawn as regular as the space available permits.

In each of the twinned heptagons smaller heptagons have now to be drawn, such as those shown with centres at N and P. Each of these heptagons has its centre identical with the centre of its larger surrounding heptagon, and is drawn of such a size that

In the previously described arabesques, the pattern lines were drawn through the centres of the construction lines. In the arabesque now under consideration this is not the case. Each primary construction line, that is to say, each side of a polygon, is to be divided by two dots into three equal parts. The pattern lines are drawn through the dots. Some of the pattern lines have been drawn in as dotted lines in part of the figure. These will serve as a guide to enable the student to complete the pattern with facility.

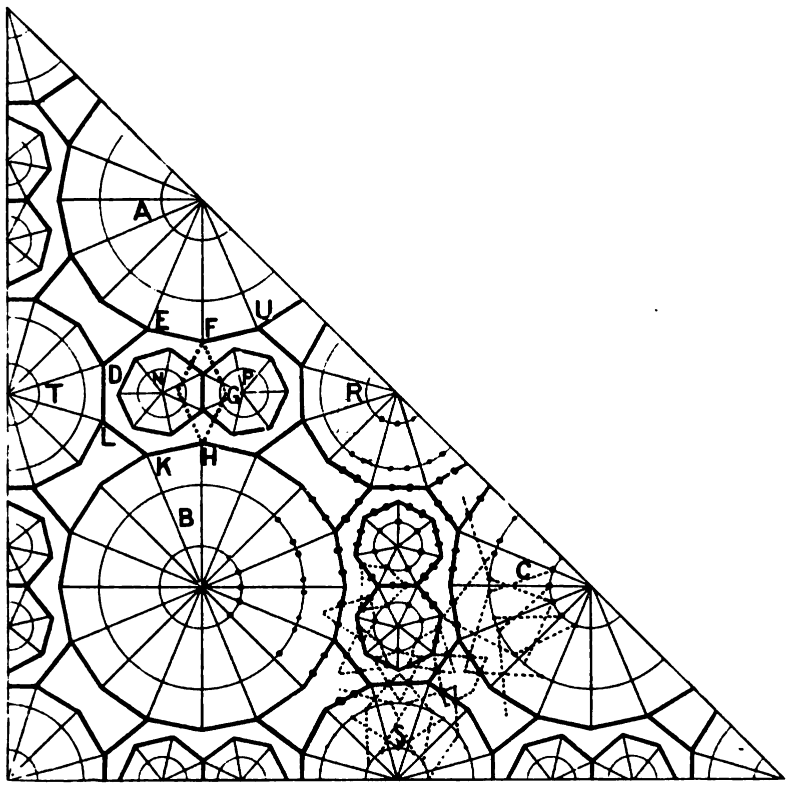
Supposing it is required to discover the construction lines of any given arabesque, proceed

as follows. Mark the centres of all the larger spaces included in the pattern, excepting, as a rule, the star-shaped spaces. Join these centres. The polygons thus produced are the primary construction lines. Supposing it is required to copy an arabesque that exists on a ceiling, or in some other inaccessible position, a similar method will suffice. On looking at the pattern, it is easy to imagine lines joining the centres of the larger spaces, which lines describe polygons. A rough sketch may be made of these imagined polygons. From this, at leisure, an accurate drawing may be made. In doing so it is necessary to make the different polygons as symmetrical as possible, and, so far as possible, having their sides all of equal length. Guided by this rule, and after a little practice, any complicated arabesque pattern can usually be solved in ten minutes. On the other hand, I personally have failed to solve some of the apparently more simple patterns despite a more extended study.

It will be advisable to conclude with a few remarks on some of the rules observed in Mohammedan decorative art.

One of the objects of decoration is to prevent the eye being displeased by monotony. A geometrical pattern, however elaborate, if used too much, will produce that effect of monotony that it was intended to prevent. It will then become as tedious to the eye as a Greek fret was to Ruskin, or as a cheap floral wallpaper may be to anyone else. In some of the best buildings in Futteypur-Sikri, the artist has nearly worked up to the standard of discarding each pattern as soon as he had used it once. In Birbul's house, for instance, a number of richly-decorated pilasters are present in the different rooms. Each pilaster has, on its face fronting the room, three carved panels. On each pilaster the upper and lower of the three panels bear the same pattern, but the middle panel always carries a different pattern, and the patterns used on one pilaster, so far as I

FIG. 15.



METHOD OF CONSTRUCTION OF PATTERN SHOWN IN FIG. 14. As shown in lower part of the drawing, each side of a polygon is divided into three equal parts by two dots. The pattern lines are drawn through these dots.

am aware, do not occur on any other. These patterns are nearly all geometrical, but a few are floral, thus further preventing any impression of monotony. One of these pilaster patterns is shown in Fig. 5.

That the pattern should be adapted to the space it has to occupy is a truism observed in almost every system of art. In the case of geometrical patterns, this truism admits of a simple geometrical expression, which, with rare exceptions, is adhered to by Mohammedan artists, and ignored by European artists when copying Mohammedan designs. In all the patterns used to illustrate this paper, star-shaped spaces occur at regular intervals. The rule very generally observed in Mohammedan art in India is that each corner of the panel is occupied by a quarter of one of these star-shaped spaces. If several repeats of the pattern occur in the panel, half stars will occur along the sides, besides quarter stars in the corners. The panel always contains a whole number of repeats. If the pattern contains eight-pointed stars, the space included in the stars may be filled up by fylfots (or outlines of that nature), and then adherence to the rule is only to be discerned on studying the construction of the pattern. In some of the perforated stone balustrades that form so pleasing a feature of the buildings in the garden of the Taj at Agra, the pattern has been visibly and greatly distorted to ensure compliance with this rule in the space available. The tomb of Itimyad Ud Daula in Agra offers a striking illustration of the observance of this convention. Worked into its marble mosaic are hexagonal, octagonal, decagonal, and dodecagonal patterns, in the greatest profusion, but in every panel, whatever its size and shape, quarter stars are always to be found in each of its four corners. The difficulty of designing the building must have been greatly added to by the observance of this rule. One is tempted to suspect that the building was designed to fit the patterns.

In Mohammedan art as it occurs in Egypt and Spain this method of adaptation to the space is sometimes followed. At other times a different plan is adopted, an example of which may be found in Fig. 13. As already explained, this drawing represents only a quarter of the complete panel. The border is therefore only shown on two sides, indicated by double lines. Had the pattern been used by a Mohammedan in India, the corner would have been occupied exactly by a quarter of a star, and half stars would have occurred along the sides. But the Moorish artist has put more than a quarter of a star in the corner, and more than half stars along the sides. The arrangement is such that the rays of the stars along the sides form a sort of inner border which is accentuated by the colouring adopted in the original design.

Owing to observance of this rule a panel of given shape is not suitable for the reception of any and every pattern. If the panel is a square, or if it is made up of a whole number of squares, it may be decorated by an octagonal pattern, or by those octagonal and dodecagonal arabesques whose repeat is a square. The repeat of a hexagonal pattern is usually a rectangle whose diagonal forms an angle of 60° with the base. Such patterns are, therefore, not applicable to square panels, but only to panels that are rectangles of this proportion, or to panels that may be regarded as made up of such rectangles. The repeat of arabesques whose primary construction lines include decagons is usually a rectangle, whose diagonal forms an angle of 36°. In "Les Elements de L'Art Arabe," by Bourgoine, may be found a large collection of arabesque patterns. In some of these patterns that contain 14-rayed stars, the unit of pattern is a rectangle whose diagonal forms an angle of about 38°. With sufficient knowledge a pattern may be found to suit a rectangle of almost any shape.

A few words may be added as to the amount of accuracy needed and advisable in drawing geometrical patterns. In elementary textbooks of design it is commonly asserted that pattern outlines look better when drawn in by hand than when drawn in by compass and rule. The truth of this statement may be admitted without reserve so far as the simplest pattern shapes and outlines are concerned. With regard to less simple patterns, however, some reservation is necessary. If a hexagonal pattern is made with the aid of construction lines that have not been drawn at exactly the correct angle, every hexagon in the pattern will be distorted. If lopsidedness occurred in a single hexagon it perhaps would not matter. But when every hexagon is lopsided to the same extent, and in the same direction, the effect is cumulative and unpleasant. The suggestion that the artist was trying to draw hexagons and failed because he didn't know how to do so, is a suggestion that obviously should be avoided. If, however, the construction lines of a hexagonal pattern are drawn in

with accuracy, the pattern may well be drawn in by hand.

Arabesques are usually found drawn accurately. In the case of the more complicated arabesques, this would seem to be necessary to produce their full æsthetic effect. But a relatively simple arabesque, such as that shown in Fig. 12, may be distorted in order to make it fit the space; that is to say, to get exactly quarter stars in each of the corners of the panel. In order to do this it is necessary to draw first the construction lines, modified or adapted to the space, and then on these lines to draw the pattern.

By observing which patterns were placed in prominent positions and which were placed where they could not attract much notice, it is possible to arrive at some ideas as to what features of a pattern were considered good by Mohammedan artists. A pattern containing several lines crossing at one point like the spokes of a wheel, as already mentioned, is not much used. The best patterns are those in which all the constituent spaces have either a radial or a bilateral symmetry, that is to say, are free from lopsidedness. A pattern is bad if it contains spaces of the same shape but differing slightly in size. If a construction leads to such a result, the pattern must be modified so that the spaces become either identical in size or else widely different. Cases have been mentioned in this paper in which gracefulness in a pattern is obtained by drawing it in conformity with some geometrical rule. Cases also may be found, though rarely, in which the geometrical method leads to a clumsy result, that can be remedied by freehand drawing.

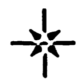
DISCUSSION.

The CHAIRMAN, in opening the discussion, said, Mr. Hankin's claim on their attention was that he had discovered at Futehpur Sikri, the Windsor of Akbar and his son Jehanghier, in the bath-room attached to the *Jodhbai Palace, the actual draughts of some of the geometrical projections on which "the Saracens" are believed by many, and Mr. Hankin shares their belief, to have planned the characteristic patterns, or at least the more elaborated of the patterns, known as "arabesques," used by them in the decoration of plane surfaces with sculpture, mouldings, and paint, and mosaics, encaustic tiles, and inlays of mother of pearl, ivory, ebony and metals, and, in the case of carpets, hangings, and other textile fabrics ["Turkish tapestry"], with broidery in "blue and purple and scarlet." This is the narrowly limited technical question Mr. Hankin's discovery revives, and yet it is impossible to discuss it, even within its most closely restricted technological scope, with any adequate intelligence, independently of its relation to the wider question of the origins of the inspiration and constructive features and mechanical methods of "Saracenic" art—so-called. The earliest building in Arabia that can be unhesitatingly attributed to the Shemitic Arabs, as distinguished from the Hamitic Adites, is the *kaaba*, or "Cube-house" at Mecca, and as rebuilt in the days of Mahomet himself, it was the work of a Greek, called Bakum by the Arab writers, and a Copt. They were in charge of a large cargo of "Greek glass" for the decoration of a Christian church in Abyssinia, and having been shipwrecked near Jidda, were impressed by the Khoreish Arabs for the restoration of the *kaaba*. The Caliph Omar, the successor of Mahomet, built the "Sacred Mosque" (*masjid'l-haram*) round, or rather foursquare, about the *kaaba*, and Burkhardt was quick to notice that the only good decoration on it was of Greek design and workmanship, and that all that was, as might be presumed, of native handicraft, was most coarsely and ignorantly executed, some of the pillars of the colonnade being set up in their places upside down. Second in sanctity to the Mosque at Mecca is the "Mosque of the Prophet" (*masjid'un-nabi*) at Medina. As built by "the Prophet of God" himself, it was a plain building of sundried bricks, unhewn stone, and date palm stems and branches. It was extended by the Caliph Othman, the successor of Omar; he using hewn stone and Indian teak wood on the work. At the beginning of the eighth century it was entirely reconstructed by the Caliph Walid I., the 7th Ommiad Caliph, and 12th from Mahomet, who, ambitious to make it the most splendid public building in the world, asked the contemporary Roman Emperor at Constantinople to supply him with Greek workmen for the purpose; and the Emperor sent him 40 Greek and 40 Coptic workmen, with 40 loads of "Greek glass," beside silver lamp chains, and other finely "arted" appliances, for the more decorous furnishing of the Mosque. This same Walid had previously, when about to build the famous *jami'-masjid* at Damascus, and the so-called "Mosque of Omar" at Jerusalem [the *kubatu's-sakhrah*, or "Dome of the Rock" of the Muslims, because occupying the site of King Solomon's Temple], entered into a regular contract with the Roman Emperor at Constantinople to supply him, according to his need, with *fsefysa* [also written *fuseyfisa*, and *fesfesa*], this Arabic word for "Greek glass," being none other than the Greek word *psephos* "a pebble." The "Mosque of the Prophet" at Medina was

* Jodhbai, was the Rajput Princess of the House of Jodhpur, who married the Emperor Akbar, and became the mother of his son Prince Selim, better known by his imperial name of Jehanghier. The Jodhbai Palace was sacrilegiously and outrageously blown up by us as an experiment in military mining in 1840.

the first Muslim building that in construction or decoration varied from the pre-existing Christian buildings in Syria and Egypt, and signalised the dawn of a new order of architecture. But Egypt was the centre whence the perfected "Saracenic" art, so-called, radiated Westward over "tawny Spain," and Eastward beyond "the farthest steep of India." Of the "Mosque of Omar" at Cairo, founded in the middle of the seventh century, and rebuilt at the beginning of the eighth, the record is that the pulpit therein was taken from one of the churches at Fustat, the old suburb of Cairo that gave its denomination to "fustian," and set up in the mosque by the Copts engaged in its construction. The "Mosque of Ibn Tulun" was built late in the ninth century, under the direction of a Copt named Buktur. It presents the foremost examples to be found in Egypt of the use in Muslim buildings of the scrolled and geometrical decorations, specifically termed "arabesques." The oldest example of "Saracenic" architecture in Spain was the mosque, now the Cathedral, but still called the "Mesquita," at Cordova, built by Greeks expressly brought from Constantinople, late in the eighth century, by the Caliph Abdurrhaman; who, like Walid I. in the case of the "Mosque of the Prophet" at Medina, was determined to make the Mosque of Cordova the wonder of the world. The distinctive "Saracenic" style of Spain reached its highest splendour, during the thirteenth and fourteenth centuries, in the enchanting elegance, and brilliant luxuriousness of the Alhambra [*kalat al hamara*, "Castle Red"] at Granada, and when the Turks in the fifteen century, on taking Constantinople, converted the Church of St. Sophia into a mosque, and made it "the glass of fashion, and the mould of form" to be observed of architects throughout Islam, and would thus have renewed the direct influence of Byzantine art on "Saracenic" art, the Mosques of Cairo and Cordova, still served to sustain something of the dignified severity of form, and the stately simplicity of ornamentation of Egyptian and earlier Spanish "Saracenic" art under the degrading influences of the now ubiquitous domination of "the Turks and Tartars" of Constantinople. The extension of the sphere of Islam under the Turks led to the gradual provision of an immense body of Muslim craftsmen, including Aryan Persians and Aryan Hindus, and the variety of Saracenic art known as Moresque was developed under the employment of Muslim *mistris* on buildings for the use of Christians as, for example, at Toledo. The influence of Byzantine Greek art [which itself grew out of Græco-Roman and Perso-Buddhistic art] on "Saracenic" art is to be traced not only in the austerity and reticence of its classical examples in Egypt and Spain, but in the scornful and defiant obtrusion by the "merry Griggs" in the "arabesques" they designed, of living forms, even animal forms, the representation of which is strictly forbidden to Muslims. One of the Greeks sent to build the Mosque at Medina actually sculptured a hog on the *kiblah* wall of the mosque. Mocking animal forms peer out in every direction from the fantastic "arabesques" of the Alhambra. The use of the Christian cross in the domestic architecture of the Muslims of Egypt, a practice continued to this day as a defence against evil spirits, is a most pertinent indication of the manner in which "Saracenic" art at its birth was controlled and directed by the Copts. Then:—the horizontal stripes of buff and red, so marked a feature of the street architecture of Alexandria and Cairo, are to be traced to the Roman mode of strengthening buildings of brick with courses of stone:—the arch, the "Saracens" took from the Romans, and the Byzantine Greeks, and, it might be, from the ancient Assyrians, but the typical horse shoe arch of "Saracenic" art was suggested directly by the iconic niche of the Buddhists, the curves of which were determined by the head and shoulders of the image standing, or sitting, within it:—and the simpler, or purely geometrical forms of "arabesque" work grew out of the necessity of using wood when employed in tropical and semi-tropical countries for the ornamental covering of plane surfaces, in the form of pannels, in order to counteract the effects of warping. The dome is directly of Byzantine derivation, and indirectly Assyrian. The lightness of the "Saracenic" buildings may possibly be derived from the tents of the Arabs, and the inspiration of the airy date palm, while the extended width and flatness of the walls, and the decoration of them with "arabesques," is certainly due to the practice followed in all Oriental countries on occasions of domestic rejoicing, and popular fairs and festivals, of erecting vast latticed booths and smothering them all over with palm branches and long twines of creepers and garlands and festoons of all kinds of flowers, after the manner of the *gloirettes* to be seen in southern France, and sitting eating and drinking and making merry in them for days together. The minaret he would identify with the cypress, or the cypriform tamarisk of Persia, "the Shaft of Isfendiyar." The rapid diffusion of "Saracenic" art over the whole area of Islam was greatly promoted by the immemorial Oriental customs of artizans travelling about from country to country and offering their services to the rich and the mighty, and of great conquerors carrying away the artistic treasures of the countries they subjugated, and making captives of the artizans of the vanquished for the adornment of their own palaces. In this way, Nebuchadnezzar (2 Kings xxiv. 14-16, and Jeremiah xxiv. 1) carried off "the carpenters and the smiths," "and all the craftsmen" that were in Jerusalem to Babylon; and Xerxes robbed some of the cities of the Greeks of their most sacred statues (Strabo xi. 11, 4—xiv. 1, 5; Pausanias i. 8, and 16—iii. 16—viii. 46, &c.; and Arrian xix.); and that the Sultan Selim I., when he annexed Egypt to the Ottoman Empire in 1516, deported the whole of the higher class of craftsmen of the country to Constantinople, leaving behind only a

few of the lower craftsmen, engaged in household and domestic arts, such as the embroiderers of "arabesques" on caps and robes and shawls,—who to this day are for the most part Greeks. This was the death blow to the exemplary tradition of "Saracenic" art in Egypt. It is by such natural processes that in every age the arts of human life have arisen into being, reached their zenith, and then declined, and often perished altogether. When the Greeks were reduced to "devil" for the Aryan conquerors of the Western Roman Empire, and the Shemitic conquerors of the Eastern Roman Empire, they created on the one hand Gothic art, and on the other "Saracenic" art, and just as Gothic art took its varying phases in Germany, Italy, Spain, France, and England, "Saracenic" art assumed its several local types in Egypt, Spain, India, and Central Asia. So long as it was fashioned by actual Aryan hands it was preserved in the pristine purity of the style of Cairo and Cordova, but when it came to be manipulated by the Turanian and the Negro races it degenerated into vulgarity and inanity. It was indeed the unreserved absorption, on absolutely equal terms, of the Black and the Yellow races within the pale of Islam that led to the decadence of Saracenic civilisation in every department of its activities, and to the stagnation and corruption in which Islam has been sloughing for the past 400 years. The essential principle of "Saracenic" art is pictorial, it being mainly directed to the decoration of wide extended plane surfaces, as of vast trellissed arbours, with deep glowing colouring, rich and warm reds and blues and yellow [gold]; sculptures, except in India, or mouldings being very sparingly used, or, where used, employed in many instances simply to enhance the effect of the colouring, as on the Alhambra. Yet this very "Arabesque" style of decoration, the essential feature of Saracenic art, was not an invention of the Arabs. It was known to the Greeks and to the Romans, and the Buddhists; it was greatly developed in the Byzantine [*i.e.*, the Græco-Romano-Perso-Buddhistic] period, and is seen in as complex elaboration in the "Palace of Nero," and the original cornice of St. Sophia—with the Buddhistic goose recurrent all along its flowing scrolls,—as in the Alhambra, or at Futehpur Sikri. Finally in regard to the technical methods of Saracenic art, and concentrating attention solely on its method of planning out ornamentation, *i.e.*, on its "arabesques," which is the question raised by Mr. Hankin's most interesting and suggestive discovery, it would appear that the Greeks habitually applied geometry to the perfection of decorative design. Decoration must, ultimately have a geometrical basis; and must be controlled by geometrical law, however unconscious the decorator may be of its operation. More than that, where decoration is attempted in conscious violation of geometry it rapidly lapses into indecorum and fatuity; furthermore there is good decoration that to the inartistic eye appears to be geometrical outlining pure and simple, but which really is entirely of artistic inception and draughtsmanship. And no doubt the Oriental craftsman of Saracenic art, including the Indian, kept up the tradition of the Greek use of geometry in the skeleton lines of their schemes of ornamentation; and we have indeed an obvious proof of this in Mr. Hankin's discovery. All this may be granted, and it cannot be gainsaid. Nevertheless, he [Sir George Birdwood] was convinced that the inspirations of artistic decoration came directly all from animated nature; and that the most inspired of the inventors of the decorative types derived from this ever springing fountain of artistic impulses and imagery, never had a thought of geometrical proportion in their minds. Much of what passes for geometrical ornamentation is due to the form imposed on it by the material used for its production, such, for an instance, as matting, wherein the graceful undulations of a snake work out in a crude "key pattern." The gradual conventionalisation of a design leads also to its gradually taking on more and more of a geometrical aspect; and again the decay of artistic inspiration, or of technical dexterity, will conduce to the deterioration of an ornament to the baldest of geometrical formulas. The women of the fisher folk in India universally mark their arms with a representation of four little fish smelling at each other's heads, and wagging their tails, by the right, to the four points of the heavens, E. S. W. and N. But in many parts of India this charming caste mark has become atrophied to four straight lines, arranged as an equal-armed cross, with a four-rayed star at their point of intersection, this star being formed by the meeting of the short reflex lines meant to figure the heads of the four little fishes; thus:—



Even where a decorative scheme is deliberately designed on a geometrical basis, it must not be conceived in a geometrical spirit, or draughted with geometrical implements. It must be inspired by artistic passion, and drawn with the fervid touch of the artist's own hand. All the geometrical ornament of the Mosque of Ibn Tulun is cut in the plaster with the hand; at the Alhambra the florid arabesques are in many places cast from moulds; and only the rare colouring of the Alhambra, and the grace of its cypriform pillars and arches, and its picturesque perspectives, serve to veil the mechanical monotony—as compared with freehand geometrical decorations of the "Mosque of Ibn Tulun"—of its "arabesques," after "Tulun," and before, "of its arabesques," a dash thus, when,—of its "arabesques." The life-giving touch of the artist's hand is everything in decoration, just as it is in painting and sculpture—in the domain of "fine art" as it is clumsily phrased; and for his (the Chairman's) part, he did not care to palter with that cardinal fact in art for any commercial consideratio

or advantage. The Code of Manu says that "the craftsman's hand is always pure." The artist craftsman's hand is in truth divine, for it is the hand of a Creator, and its work cannot be done by a rule and compasses, although it should be able to bear the test of the most searching — short of Procrustean stretching and docking—geometrical analysis and "registration."

Mr. LEWIS DAY said he would like to express his appreciation of the admirable way in which the author had shown the complicated designs side by side with the other designs; the manner in which the paper had been illustrated was an object-lesson in how such a paper should be delivered. Mr. Hankin had shown very plainly how the patterns might have been done, but whether they were always done in that way was quite another matter. The author had spoken as a mathematician and not as a designer; He (Mr. Day) could not imagine a designer always going to work in the manner described. There were so many ways in which the elaborate patterns which had been shown could be constructed. In demonstrating to students the construction of pattern, he had often discovered half a dozen plans on which a given drab design might with equal reason have been built, and it would be a bold man who would venture to say which was the actual way in which it was really done. In one particular case in which the author had explained how a particular pattern was made, he (the speaker) had discovered for himself many ways in which the same result could be arrived at, and the one shown was not one of them. There could be no possible doubt, however, as to the ingenuity of the author's explanations. The way in which Mr. Hankin built up sundry patterns from circles was not the way a designer would set to work. He had shown a cusped arch in which the cusping was supposed to be got out of circles; he did not believe any designer ever cusped an arch in that mechanical way. All patterns repeated on the geometrical basis, and geometric patterns exhibited the basis on which they were made. If all the elaborate lattice work on which intricate designs were set out were drawn on paper, it would be found that it was so complex that anybody—except perhaps the author, would get lost in the mist of lines; they must therefore look for some other way in which the patterns were formed. He had always felt very strongly that the simpler Arab patterns found in the Opus Alexandrium were built up of little triangles, &c., that was more likely the way in which the more elaborate work was done, and not by means of templates. The patterns, by the way, which the author had stated could be built up by putting together dodecagons could equally be arrived at by striking circles, and at the intersection of those circles drawing straight lines from intersection to intersection. It had to be remembered that when a designer drew those elaborate patterns he did not have the whole area of lines, &c., in front of him; he designed a little piece which he could keep in his mental grasp. He had only to keep that small unit in his mind; he knew what the effect of repeating the unit would be. Speaking as a practical designer of geometric pattern Mr. Day was conscious that the way in which the geometric designs exhibited were built up must have been in some more simple manner than the author had described; but, nevertheless, he was delighted at the ingenuity with which Mr. Hankin had pointed out how the things could be done, and he had shown him, as a student of the basis of design, different ways of arriving at the same results he had himself reached by another way. He proposed a cordial vote of thanks to Mr. Hankin for his intensely interesting lecture.

Prof. O. MULLER said the Chairman had stated that it was against his feeling as an artist that there should be a sort of geometrical basis for designs, but yet it must be allowed that the designs under discussion had a geometrical basis. There was a tendency for a pattern to be good or bad according as it approached more nearly to a proper geometrical basis. That was very apparent in many of the pierced screens in the buildings at Agra. Some of the buildings were built at a time when art was not good, or when good artists were not employed; a screen was fitted into a panel which it did not suit. But, on the other hand, if one visited a better building, built at a time when better artists were employed, it was to be noted that the screens fitted into the panels, and the patterns always connected up properly. There were in Agra some 30 or 40 known patterns of different pierced screens. The present Viceroy of India, Lord Curzon, had, to his lasting honour, taken up the question of the preservation of the wonderful buildings at Agra and elsewhere in India. He had not only caused them to be kept in good repair, but large works of restoration had been carried out. When Lord Curzon saw the tomb of Itimad-ud-Daula, he noticed that the balustrade of the marble pierced screens, which ought to have been along the top of the building, was wanting; as a matter of fact it was taken down just after Agra came into possession of the English, by some British General, and, as far as they had been able to trace, it was broken up and burnt to make lime. The Viceroy said he would like to see the screen put up, and the problem was how properly to restore the balustrade. From the minarets at the corners it was possible to judge how high it was, and from the marks still left on the edges, one could see where the pillars stood, and get at the size of the panels. It was found that the panels on one side were of different lengths, and consequently each pattern was different. From the methods which had been demonstrated that evening, it was comparatively easy for Mr. Hankin to find out which pattern would fit into the panel. Mr. Hankin submitted a design for the balustrade, which was put up on one side; the next time the Viceroy visited the place he

approved of it, and the balustrade had now been restored on all four sides. The author's method had therefore enabled the balustrade to be put up probably in exactly the same form in which it was there when it was unfortunately used for making lime and whitewash. The Chairman had made the remark that from his experience in Bombay, workmen made patterns by sitting quite close up to the work and having no construction lines; but the fact that the patterns could be produced by geometrical construction lines, and that they were in this sense the basis of the work, did not seem to him to lose any value. It might just as well be argued that because the circulation of the blood was unknown to the great mass of humanity that it did not exist. He therefore urged that when it was discovered that there was a geometrical basis for constructing such patterns, although some people might be able to make the patterns without knowing the basis, it did not prove that was not the basis on which the patterns were really formed, but simply that those people were unconscious of them. He thoroughly agreed with Mr. Day that probably artists and designers did not set to work by drawing little circles and geometrical patterns; they drew a free hand pattern, more or less, and evolved their scheme out of their inner consciousness; but when such designs were reproduced they had to be worked up in an office, *i.e.*, they had to be geometrically rectified; in the same way as when pictures were hung on the four walls of a room, some mechanical means had to be adopted to see that they were hung in a straight line. He therefore urged that in that manner mathematical methods of construction were probably employed to correct designs that were made by artists, even where the idea of a mathematical basis never crossed their minds.

The CHAIRMAN said he would like to say in regard to Professor Muller's remarks that it was high time steps should be taken to preserve the wonderful buildings at Agra. The palace in which Mr. Hankin made his discovery was sacrilegiously destroyed by the English in 1840 in carrying out some whimsical experiment in military mining, when it was practically blown up.

Mr. SYDNEY HALL said it was 30 years since he was in India with the King, when he hoped he admired as he ought to have done all the pierced marble screens he saw, but he remembered running away from them to see the natives diving from a very high wall into a deep pond, and sketching the scene. He was commanded on that occasion to draw many things, elephants, tigers, and temples, and he did his best, but he was happy to say that he was not commanded to draw one of the arabesques which had been shown by the author; if he had been he was perfectly certain he should have gone stark staring mad. If he ever went to India again he should take particular care to carry with him plenty of paper patterns of octagons, pentagons, heptagons, and dodecagons, and so possibly save himself from going mad.

Mr. PHENÉ SPIERS said that many years ago when he was travelling in Egypt he had occupied himself by endeavouring to find out the problems on which the mosaics were set-out in Cairo, and he arrived at a great number of solutions. The 12-sided star puzzled him a great deal, but he eventually arrived at very much the same result as the author. He found out that in the 12-sided star the pattern between the stars naturally depended upon the distance of the 12-pointed stars from one another, and that by placing them at varying distances combinations were arrived at which were not at first apparent in the design. He was inclined to agree with Mr. Day that a great many of the patterns shown were not based exactly on the geometrical system; in fact in many cases he thought they were probably the result of some instinctive feeling. He remembered some years ago, when he was superintending the execution of certain drawings for a great many beautiful buildings in India, Major Mant for whom the drawings were being prepared, said it was only necessary to set out the centres and axes of the panels, because the artists themselves would put in all the details. Professor Aitchison tells the story of an Englishman who was obliged during a violent storm to take refuge in a cave. Whilst he was there, a native came in with a small barrel in his hand and some materials, and drew on the ceiling one of the most beautiful designs that he had ever seen. He found out from the native the name and address of his parents in order that he might congratulate them on having such a skilled son, but the father replied that he looked upon the son practically as a dolt, because he only knew one design, whereas one of his brothers knew three or four patterns. There was no doubt the workmen had some instinctive power because they, without little intelligence, and certainly without any knowledge of geometry, produced the most beautiful designs. He believed that throughout India the workmen worked without a plan prepared by an artist as was the case in this country.

Mr. HANKIN, in reply, said a very important point was raised by the Chairman and Mr. Day as to the part played by free hand drawing *versus* geometrical design in the products of Saracenic art. He had studied the matter particularly at Futteypur-Sikri, and there geometrical methods seemed to have the day, whereas in other buildings in Agra and in all work produced at the present day geometrical methods had fallen into the background. One reason why he had ventured to bring the subject forward was because he was aware how completely the modern workmen in India were incapable of drawing the designs which Mr. Day said could be drawn instinctively or by using geometrical methods. They had completely forgotten these methods. In the old work of four centuries ago, there were extremely complicated arabesque designs, and no suggestion of a method had been brought forward by which they

could have been drawn except by the methods he had stated in his paper. In Futteypur-Sikri, not only were the geometrical patterns of that nature, but even the curvilinear designs were drawn to a great extent by means of a pair of compasses and similar geometrical methods. One of the curved outlines he drew by means of overlapping circles was based on a pattern in Futteypur-Sikri, and several other of the patterns in that place could be similarly constructed, and their solution was often a matter of extreme difficulty. It was the simplest example that he could find; in fact it was the only example sufficiently simple to have remained so long in his memory. In the later work in India, such as was found in the Taj and the Palace at Agra, graceful floral outlines were found, but to the best of his knowledge they were not drawn by means of a pair of compasses, but by the free hand guided by the free artistic sense of the artist. The buildings at Futteypur-Sikri were in a way archaic. The idea had often suggested itself to him that perhaps the artists who had to do with the buildings at Futteypur-Sikri were, when judged by English standards, people of low artistic powers; it was almost probable that they were incapable of drawing a graceful curve without some such mechanical method as a pair of compasses; but in the later work and in the higher products of Indian art, no traces were found of such a hindering influence. The fact that these geometrical methods were so completely forgotten in India was no hindrance to the production of artistic products. In their place it would be found that in Agra and its neighbourhood, the stone masons produced floral outlines of the greatest gracefulness and of the greatest suitability to the purpose they had in view. The fact that they had forgotten the old trammels of geometrical pattern was not a hindrance but a help to their work. If one went through the slums of Agra, or any other town in that part of India, the façades of houses would often be seen decorated with the most exquisite stone carving, which in his opinion equalled, if not surpassed, the more famous work of earlier days.

The resolution of thanks to Mr. Hankin for his exceedingly interesting paper was then put and carried with acclamation, and the meeting terminated.

THE FISHING INDUSTRY OF JAPAN.

The fish existing in Japanese waters are very varied and very plentiful; the most useful kinds in the northern part of the Empire are the herring, salmon, and cod. In the southern waters are found the sardine, anchovy, mackerel, bonito, tunny, shark, oysters, shrimps and prawns. The fresh-water fishery is not so important as the marine fishery, as there are few large lakes and rivers. In the warm seasons nearly the whole coast of Japan is washed by the Kuroshiwo (the warm current), or its branches. Thus the important migrating fish of the southern region are caught in the northern part of Hondo (main island), and also in Kokkaido, late in the summer or in the autumn. In the winter and spring, the Kuriles, Hokkaido, the north-eastern and north-western coasts of Hondo, are washed by the Oyashino (the cold current) or its branches. The number of vessels engaged in fishing on the Japanese coasts is said by the Imperial Fisheries Bureau of the Department of Agriculture and Commerce at Tokyo, to amount to over 400,000. Fish are sold fresh in enormous quantities in Japan, and fresh fish markets are extended year by year as the convenience of transportation increases. Considerable quantities of fish are also preserved, and many kinds of fishery products are utilised to a degree not equalled by many other countries. The most important seaweeds are "kombu," "amanori," "tengusa," and "funori." The greater part of the dried kombu is exported to China for food. Tengusa is made into a kind of isinglass called "kanten," and the kanten is also exported to China and other countries in large quantities. Amanori is made into sheets like paper and dried. It is called "hoshinori," and is considered a great delicacy. Funori is also made into large sheets like paper and dried. It is used only for starch. The methods of curing fishery products have greatly improved of recent years. This is especially seen in the canning business, which was introduced some thirty or forty years ago, and has grown considerably since the Japan-China war. Every year a little over five million pounds of fish of all kinds are preserved in tins. Brine-salting, or curing fish in strong brine, has been introduced recently, the salting of fish being formerly confined mostly to dry-salting. This has made it necessary to improve the Japanese salt industry in order to obtain a better quality of salt. As to the export trade, dried cuttle fish, dried "sea-ear," dried shark's fin, dried kombu and kanten are the most important articles exported to China. The exports of Japanese fishery products has long since been in a prosperous condition, the exports always exceeding the imports. The total exports to China have increased three million yen (£306,250) within the last ten years. Fish oils, including herring, sardine, cod-liver and whale oil, are exported to Europe in large quantities. Pisciculture in Japan includes the culture of fish, shell-fish, reptiles, and even algæ. Some of these have been cultivated from ancient times. Among these are the gold-fish, carp, eel, grey mullet, oyster, pearl oyster, turtle and amanori (an alga of the genus *Porphyra*). Most of them are cultivated in ponds, except shell fish and algæ which are reared in a bay or creek. The cultivation of amanori which is known only in Japan, is extensively carried on in Tokyo Bay and the Sea of Hiroshima-Ken. This seaweed is collected by means of the branches of trees or bamboos, driven into the sandy flats, which are exposed at the time of the ebb tide. To these, spores of the alga attach themselves and grow. These branches are renewed every year.

Funori is also cultivated in a primitive but effective method in some parts of the country. This is by simply throwing stones in the shallow water to give the alga a place to grow on. Carp culture is the most popular of the artificial fishing industries. It is carried on to a large extent in ponds, and sometimes even in rice fields. The culture of the soft-shell turtle is limited to one place in the suburbs of Tokyo, and requires very considerable skill. The artificial propagation of salmon has also been practised. In the year 1878 the Agriculture Bureau collected the eggs of salmon in certain rivers in Mügata-Ken, Nangano-Ken, Ibaraki-Ken, and Hokkaido, and distributed 356,500 fry into many rivers and lakes, and in 1890 the number had increased to 1,130,000 but without much success. There appears, however, to be one place which shows good results from this work. It is Lake Chuguji in Nikko, where there were no fish at all before the propagation of salmon. The quantity of fish in this lake is now so great that it supplies an abundance, and it affords excellent sport for anglers. A Fish Commission was appointed in 1893 to carry on more extensive scientific investigations relating to all branches of the fishing industry in Japan, and this Commission lasted until 1898. In that year the present Fishery Bureau was organised, and the work has been carried on more scientifically and systematically. While this work has been carried on by the Central Bureau, the Government has for a number of years encouraged the establishment of local experimental stations, and has given a bounty to each station. As a result there are now thirty-two experimental stations distributed among thirty-one prefectures. Fishing schools have also been started in different parts of the country. The Government also founded a school in Tokyo in 1897 called the Suisan Koskujo, or Fishery Institute. There are a few private Associations organised with the object of uniting those interested in the fishing industry, and of studying all important subjects in connection with the fisheries. Among these the Fishery Society of Japan is the oldest organisation. It was founded in 1881, and now has nearly five thousand members. This society publishes a monthly journal. There is another Association called the Society for Salt Industry of Japan which devotes itself to the improvement of the salt industry. It was established in 1896, and also publishes a monthly journal for its 1,500 members. Both of these organisations are situated in Tokyo.

THE ALCOHOL INDUSTRY IN FRANCE.

A Congress, recently held in Vienna, called attention to the many uses to which alcohol is adapted, especially for manufacturing a safe and cheap illuminating gas and for motors, for automobiles, &c. The inventors of certain novel processes for manufacturing alcohol have been interested in recent experiments tried in Denmark for distilling alcohol from peat at an estimated cost of one halfpenny per gallon. It is to be manufactured to replace gasoline and petroleum for illuminating purposes, and for motive power. France and Germany have, it is said, watched these experiments with great interest, knowing that if they are successful they will make an industrial revolution. The French Government has recently issued in the "Bulletin de Statistique et de Legislation Comparée," the official statement of the production of alcohol in France during 1903. It appears from this statement that 113,879 firms, whose names are registered in France, were engaged in making alcohol in that year. Of these 191 used farinaceous substances to produce the alcohol, 2 used potatoes, 289 used molasses and beets, 8,654 used wines, 7,526 used cider and perry, 92,783 used mash of different kinds, 4,363 used fruits, 153 used various substances, and 1 used glucose and the others sweetening materials. The 45 largest distilleries in France are situated in the departments of the Nord, Pas-de-Calais, Aisne, Somme, and Seine-et-Oise. Each of these distilleries turns out alcohol to the extent of 10,000 hectolitres (220,000 imperial gallons) annually. Since 1840 there has been a great change in the materials from which alcohols are manufactured; the quantity of pure brandy from grapes has diminished since the vines in the Cognac and Armagnac regions were injured or destroyed by the phylloxera, but it has increased since the American vines, grafted with French vines, have begun to bear. In 1903, of the total of 45,000,000 gallons manufactured, 20,000,000 were made from beets, 15,000,000 from molasses, and 8,000,000 gallons from farinacious substances. It would appear that a large number of distilleries for manufacturing alcohol from beets have been opened in France, on account of the rise in the price of alcohol and the fall in the price paid for beets at the sugar refineries. Some refineries have been turned into distilleries for making alcohol from beets.

EXHIBITION OF PROCESS ENGRAVING.

The Exhibition of Process Engraving, held in the Victoria and Albert Museum, which was opened to the public on Tuesday, the 14th inst., is a continuation of the Exhibition of British Engraving and Etching held in 1903. These like the previous ones of Lithography and Modern Illustration owe their initiation to the suggestion of the Council of the Society of Arts. This Exhibition is devoted to examples of photogravure, photolithography and kindred processes of reproduction by means of photography, including specimens of half-tone colour printing. The present Exhibition has been extended so as to include the productions of foreign countries in order that the development of engraving by photo-mechanical methods abroad may be compared with that in this country. The Bays 1 to 13 are devoted to the productions of Great Britain, while Bays 14 to 26 contain the work of foreign firms in Europe and America.

The first portion of the Exhibition is devoted to an historic section, which contains a number of objects of great interest. In the first case is an impression from a pewter heliograph plate, produced by Niépce in 1824 (a portrait of Cardinal Amboise), also MS. notes on Héliographie, 1827, 1829, and the first photograph fixed from nature, obtained by Niépce in 1827.

Specimens are exhihited of photo-engraving and photo-glyphic engraving by Fox Talbot, of Sir Joseph Swan's photo-mezzotint, of Paul Pretsch's mechanical processes, of Sir William Abney's papyro-type process, of the Woodbury process, also of various processes of photo-etching, photo-lithography, photo-zincography, and heliogravure. These historic specimens of the art are shown in the first three bays.

Examples of work in photogravure, collotype, and half-tone colour process have been exhibited by twenty-eight firms in England and Scotland. In several instances plates showing the progressive stages of the various processes are shown.

The London County Council School of Photo-engraving and Lithography, and the Polytechnic School of Photography show specimens of the works executed in their schools. In one of the cases are materials used in the tri-colour process, and chemicals used in collotype. In the foreign department the following countries are represented:—Austro-Hungary, Belgium, Denmark, France, Germany, Holland, Italy, Russia, Spain, Sweden, Switzerland, and the United States of America. Some specimens of Japanese printing, selected from the Art Library of the Victoria and Albert Museum, are also shown.

There are a considerable number of reproductions from pictures both in the English and Foreign departments, and some autogravures from water-colour paintings among the exhibits from Holland are worthy of special attention. These can be compared with the original drawings. In several other cases the original paintings are placed in juxtaposition to the reproductions.

Major-General J. Waterhouse, a member of the Committee of Advice, has contributed a valuable introduction to the catalogue, in which he explains the principles of photo-mechanical processes, and gives information respecting the dates of their introduction and development.

The Exhibition will remain open until the end of June.

GENERAL NOTES.

International Congress on Technical Education.—The Permanent Committee of the Congress have accepted an invitation for the holding of the next meeting at Milan in 1906. The date has not yet been fixed, but as it is also proposed to hold at Milan in the same year an International Congress of Commerce and Industry, it is probable that the dates for the two Congresses will be arranged so that they may take place about the same time. The Committee have had before them various suggestions for the holding of another meeting in England, and though nothing definite has yet been fixed, they are not without hope that the meeting after the one at Milan may be held in this country.

Metric System of Weights and Measures.—A Parliamentary paper just issued gives the latest information as to adoption within the Empire of the metric system of weights and measures. Approached on the subject, the Government of New Zealand replied that "until the British Government and that of the Dominion of Canada adopt the system, it would, they consider, be inadvisable for this colony to move in the matter." Upon being communicated with, the Dominion Privy Council approved a minute expressing the willingness of the Government to introduce legislation to legalise the metric system "at such time as may be agreed upon between His Majesty's Government and the various units of the Empire." Something has already been done to encourage the use of such a system in Canada. By 34 Victoria (chapter 24, 1871) it was provided that for the promotion and extension of the internal as well as of the foreign trade of Canada, and for the advancement of science, it was expedient to legalise the use of the metric system of weights and measures, and since that date weights and measures of the metric system have been used in Canada, but almost enclusively in connection with scientific investigation. Moreover, the Department of Education has distributed to educational institutions nearly 500 sample sets of the metric system, and has also equipped the principal weights and measures offices with standards of the system referred to in order that an inspection of metric weights and measures may be made whenever the demand therefore arises.

Industrial and Technical Education in Malta. — An industrial school was opened in March, 1903, and is now being conducted by the Salesian Fathers at the request of the Government, on whom the whole of the cost of the maintenance falls. The Technical and Manual School, in which drawing, modelling in clay, plaster-casting, stucco-work, and wood-carving are taught, has been in existence for some years. The attendance is voluntary, and no fees are paid. The results obtained hardly justify the expenditure involved. On this account the school is to be closed shortly, to be replaced by a development of the technical education which is at present given in the elementary schools.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock :—

March 22.—"The Present Aspect of the Fiscal Question." By Sir Charles Malcolm Kennedy, K.C.M.G., C.B. Sir Westby Perceval, K.C.M.G., will preside.

MARCH 29.—"British Woodlands." By the RIGHT HON. SIR HERBERT MAXWELL, Bart., M.P. R. C. MUNRO-FERGUSON, M.P., will preside.

APRIL 5.—"Ancient Architecture of the Great Zimbabwe." By RICHARD A. HALL.

APRIL 12.—"The use of Wood Pulp for Paper Making." By S. CHARLES PHILLIPS, M.S.C.I.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

APRIL 6.—"The Prospects of the Shan States." By SIR J. GEORGE SCOTT, K.C.I.E. ("Shway Yoe"), Superintendent and Political Officer, Southern Shan States. THE MOST HON. THE MARQUIS OF BATH, will preside.

COLONIAL SECTION.

Tuesday afternoons at 4.30 o'clock:—

MARCH 28.—The Manufactures of Greater Britain. —II. Australasia." By the HON. WALTER HARTWELL JAMES, K.C., Agent-General for and late Premier of Western Australia.

APPLIED ART SECTION.

Tuesdays, at 4.30 or 8 o'clock:—

MARCH 21, 8 p.m.—"West Country Screens and Rood Lofts." By F. BLIGH BOND, F.R.I.B.A. G. F. BODLEY, R.A., will preside.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

HERBERT LAWS WEBB, "Telephony." Four Lectures.

LECTURE II.—MARCH 20.—*Telephone Lines.*—Characteristics of telephone current—Necessity for metallic circuits—Overhead lines—Types of telephone line construction—Telephone cables—Evolution of special type of cable for telephone work—Conduits—Distribution—Aerial cables—Means of increasing range of transmission—Long distance telephony.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 20...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. Herbert Laws Webb, "Telephony." (Lecture II.)

British Architects, 9, Conduit-street, W., 8 p.m. Papers on "Decorative Painting" by Sir William Richmond, Mr. Alfred East, and Mr. Solomon J. Solomon.

Camera Club, Charing-cross-road, W.C., 8½ p.m.

Victoria Institute, 8, Adelphi-terrace, W.C., 4½ p.m. Warren Upham, "The Nebular and Planetesimal Theories of the Earth's Origin."

TUESDAY, MARCH 21...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Applied Art Section.) Mr. F. Bligh Bond, "West Country Screens and Rood Lofts."

Royal Institution, Albemarle-street, W., 5 p.m. Prof. W. Dalby, "Engineering Problems." (Lecture I.)

National Service League, Caxton-hall, Westminster, S.W., 5½ p.m. Mr. H. Birchenough, "The Industrial Advantages of Universal Naval and Military Training."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on paper by Lord Brassey, "Shipbuilding for the Navy."

Statistical, in the Theatre of the United Service Institution, Whitehall, S.W., 5 p.m. Mr. W. N. Shaw, "The Seasons in the British Isles since 1878."

Pathological, 20, Hanover-square, W., 8½ p.m.

Zoological, 3, Hanover-square, W., 8½ p.m.

United Service Institution, Whitehall, S.W., 3 p.m. Colonel A. M. Murray, "Comparison Between Continental and English Methods of Military Education."

WEDNESDAY, MARCH 22...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Sir Charles Malcolm Kennedy, "The Present Aspect of the Fiscal Question."

Geological, Burlington-house, W., 8 p.m.

Dyers and Colourists (London Section), 608-600, Birkbeck Bank Chambers, Holborn, W.C., 7½ p.m. 1. Mr. F. W. Colin Robinson, "The Dyeing and Finishing of Leather for Bookbinding; with remarks on Preparatory Manufacturing Processes." 2. Mr. H. Ley, "A Dyeing Drum Door, removable and replaceable without stopping the Drum."

Royal Society of Literature, 20, Hanover-square, W., 8½ p.m.

THURSDAY, MARCH 23...Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Royal Institution, Albemarle-street, W., 5 p.m. Mr. Thomas G. Jackson, "The Reasonableness of Architecture." (Lecture I.)

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. 1. Mr. E. H. Rayner, "The Effect of Heat on the Electrical and Mechanical Properties of Dielectrics," and "The Temperature Distribution in the Interior of Field Coils." 2. Mr. R. Goldschmidt, "Temperature Curves and the Rating of Electrical Machinery."

Camera Club, Charing-cross-road, W.C., 8½ p.m.

FRIDAY, MARCH 24...Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting, 9 p.m., Sir Oliver Lodge, "A Pertinaceous Current."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) 1. C. T. Gardner, "The Wanki to Victoria Falls Section: Victoria Falls Railway." 2. Mr. H. S. Coppock, "Design of a Double-Line Plate-Girder Railway Bridge."

Architectural Association, 18, Tufton-street, S.W., 7½ p.m. Mr. A. N. Wilson, "Sketch Plans and Working Drawings."

Clinical, 20, Hanover-square, W., 8½ p.m.

Physical, Pender Electrical Laboratory, University College, Gower-street, W.C., 5 p.m. 1. Mr. W. C. Clinton, "Note on the Voltage Ratios of an Inverted Rotary Convertor." 2. Mr. G. B. Dyke, "The Flux of Light from the Electric Arc with varying Power Supply." 3. Prof. J. A. Fleming, "The Application of the Cymometer and the Determination of the Coefficient of Coupling of Oscillation Transformers." 4. Exhibition of Cymometers and other Instruments.

SATURDAY, MARCH 25...Royal Institution, Albemarle-street, W., 3 p.m. Prof. J. J. Thomson, "Electrical Properties of Radio Active Substance." (Lecture III.)

Botanic, Inner Circle, Regent's-park, N.W., 3½ p.m.

Journal of the Society of Arts.

No. 2,731. **VOL. LIII.**

FRIDAY, MARCH 24, 1905.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

NOTICES.

NEXT WEEK.

MONDAY, MARCH 27, 8 p.m. (Cantor Lecture.) HERBERT LAWS WEBB, "Telephony," Lecture III.

TUESDAY, MARCH 28, 4.30 p.m. (Colonial Section.) HON. WALTER HARTWELL JAMES, K.C., Agent-General for Western Australia, "The Manufactures of Greater Britain. II.—Australasia."

WEDNESDAY, MARCH 29, 8 p.m. (Ordinary Meeting.) RIGHT HON. SIR HERBERT MAXWELL, BART., M.P., "British Woodlands."

Further details of the Society's meetings will be found at the end of this number.

CANTOR LECTURES.

On Monday evening, 20th inst., Mr. H. L. WEBB delivered the second lecture of his Course on "Telephony."

The lectures will be published in the *Journal* during the summer recess.

APPLIED ART SECTION.

Tuesday, March 21st; G. F. BODLEY, R.A., in the chair.

The paper read was "West Country Screens and Rood Lofts," by F. BLIGH BOND, F.R.I.B.A.

The paper and report of the discussion will be published in a future number of the *Journal*.

THE ALBERT MEDAL.

The Council will proceed to consider the award of the Albert Medal for 1905 early in May next, and they, therefore, invite members of the Society to forward to the Secretary, on or before the 1st April, the names of such men of high distinction as they may think worthy of this honour. The medal was struck to reward "distinguished merit in promoting Arts, Manufactures, and Commerce," and has been awarded as follows in previous years:—

In 1864, to Sir Rowland Hill, K.C.B., F.R.S.

In 1865, to his Imperial Majesty, Napoleon III.

In 1866, to Michael Faraday, D.C.L., F.R.S.

In 1867, to Mr. (afterwards Sir) W. Fothergill Cooke and Professor (afterwards Sir) Charles Wheatstone, F.R.S.

In 1868, to Mr. (afterwards Sir) Joseph Whitworth, LL.D., F.R.S.

In 1869, to Baron Justus von Liebig, Associate ot the Institute of France, For.Memb.R.S., Chevalier of the Legion of Honour, &c.

In 1870, to Vicomte Ferdinand de Lesseps, Member of the Institute of France, Hon. G.C.S.I.

In 1871, to Mr. (afterwards Sir) Henry Cole, K.C.B.

In 1872, to Mr. (afterwards Sir) Henry Bessemer, F.R.S.

In 1873, to Michel Eugène Chevreul, For.Memb. R.S., Member of the Institute of France.

In 1874, to Mr. (afterwards Sir) C. W. Siemens, D.C.L., F.R.S.

In 1875, to Michel Chevalier.

In 1876, to Sir George B. Airy, K.C.B., F.R.S., Astronomer Royal.

In 1877, to Jean Baptiste Dumas, For.Memb.R.S., Member of the Institute of France.

In 1878, to Sir Wm. G. Armstrong (afterwards Lord Armstrong), C.B., D.C.L., F.R.S.

In 1879, to Sir William Thomson (now Lord Kelvin), LL.D., D.C.L., F.R.S.

In 1880, to James Prescott Joule, LL.D., D.C.L., F.R.S.

In 1881, to August Wilhelm Hofmann, M.D., LL.D., F.R.S., Professor of Chemistry in the University of Berlin.

In 1882, to Louis Pasteur, Member of the Institute of France, For. Memb. R.S.

In 1883, to Sir Joseph Dalton Hooker, K.C.S.I., C.B., M.D., D.C.L., LL.D., F.R.S.

In 1884, to Captain James Buchanan Eads.

In 1885, to Mr. (afterwards Sir) Henry Doulton.

In 1886, to Samuel Cunliffe Lister (now Lord Masham).

In 1887, to HER MAJESTY QUEEN VICTORIA.

In 1888, to Professor Hermann Louis Helmholtz, For. Memb. R.S.

In 1889, to John Percy, LL.D., F.R.S.

In 1890, to William Henry Perkin, F.R.S

In 1891, to Sir Frederick Abel, Bart., G.C.V.O., K.C.B., D.C.L., D.Sc., F.R.S.

In 1892, to Thomas Alva Edison.

In 1893, to Sir John Bennet Lawes, Bart., F.R.S., and Sir Henry Gilbert, Ph.D., F.R.S.

In 1894, to Sir Joseph (now Lord) Lister, F.R.S.

In 1895, to Sir Isaac Lowthian Bell, Bart., F.R.S.

In 1896, to Prof. David Edward Hughes, F.R.S.

In 1897, to George James Symons, F.R.S.

In 1898, to Professor Robert Wilhelm Bunsen, M.D., For. Memb. R.S.

In 1899, to Sir William Crookes, F.R.S.

In 1900, to Henry Wilde, F.R.S.

In 1901, to His Majesty the King.

In 1902, to Professor Alexander Graham Bell.

In 1903, to Sir Charles Augustus Hartley, K.C.M.G.

In 1904, to Walter Crane.

A full list of the services for which the medals were awarded was given in the last number of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

FIFTEENTH ORDINARY MEETING.

Wednesday, March 22, 1905; Sir Westby B. Perceval, K.C.M.G., Member of the Council of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Flack, Albert, 264, Borough High-street, S.E,

Pierera, A. A., Alexander Institute, Hyderabad, Deccan, India.

The following candidates were ballotted for and duly elected members of the Society.—

Adams, John Henry Maudslay, Broughton Cottage, St. James's-road, Waverley, Sydney, New South Wales, Australia.

Davis, Joseph Edward, 24, Maple-road, St. Thomas, Exeter.

Dewhurst, Wynford, Chelmscote, Leighton Buzzard.

Griffith, Samuel Barnes, 8, John-street, Adelphi, W.C.

Holding, Edwin, Balmain, New South Wales, Australia.

Kilburn, Bertram Edward Dunbar, M.A., Assoc. Inst.C.E., 6, Stanhope-street, Hyde-park, W.

Lawson, Eric St. John, Bangkok, Siam.

Medley, Charles Powis, A.M.I.Mech.E., 103, Worship-street, E.C.

Mocatta, Elkan B., 31, Great Cumberland-place, W.

Munton, Frederick Thomas, F.C.S., Beaconfield, Weston-road, Runcorn.

Newcombe, Robert William, 9, Groveland-avenue, Hoylake, Cheshire.

Ross, James William George, 143, Mitcham-lane, Streatham, S.W.

Tepowa, Adebiyi, Customs House, Calabar, West Africa.

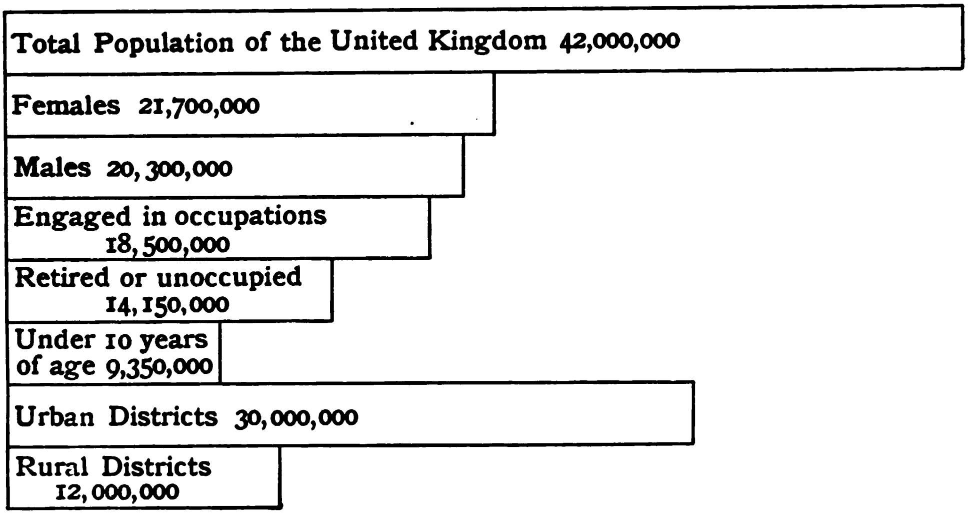
The paper read was—

PRESENT ASPECTS OF THE FISCAL QUESTION.

By Sir Charles Malcolm Kennedy, K.C.M.G., C.B., F.S.S.

Since the previous paper was read here on the 2nd of December, 1903, the fiscal question has formed the subject of debates in Parliament, of important public speeches, and of many interesting and valuable publications. Blue-books issued by the Board of Trade, the Board of Agriculture, and the Commissioners of Customs; the Census Returns of 1901; and Reports presented to Parliament by the Foreign, Colonial, and India Offices, have further elucidated the subject, which is now more clearly seen to comprise various and complex subdivisions. Our inquiry and aim is to investigate the facts thoroughly and sincerely, and then to endeavour to trace the conclusions to which they lead—to consider the interests of the Empire, the needs of the active worker, and the things with and upon which he works. We have to consider in the first place the three divisions of commerce—the home, foreign, and carrying trades—and the financial aspect of the case. Since December, 1903, the publication of the full statistics of the Census of 1901 shows the numbers, and the occupations, of the people whose interests are affected by the fiscal question. These are seen in Diagram I. The per-centage of increase or decrease in the intercensal period, 1891-1901, was:—England and Wales + 12·2; Scotland + 11·1; Ireland − 5·2; the increase for the United Kingdom being 9·9.

The population, occupied and unoccupied, above ten years of age, was 32,335,350; engaged in occupations, 18,500,000; retired or unoccupied, 14,150,000; under 10 years of age, 9,350,000. The analysis of occupations is seen in Diagram III. (see p. 484).



I.—Population of the United Kingdom.

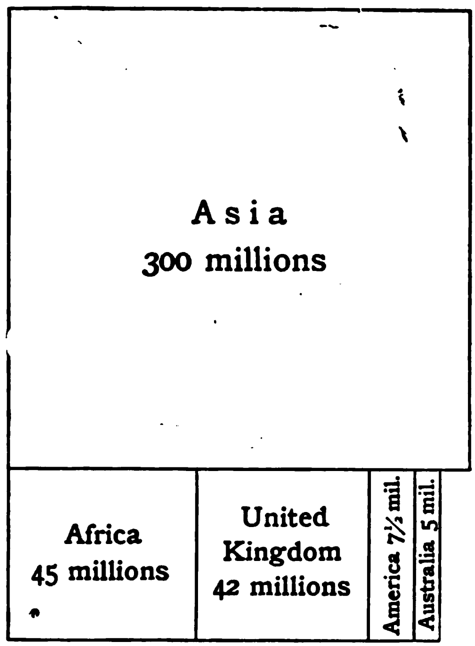
There is an increase between 1891 and 1901 in the number of persons engaged in the occupations enumerated in Diagram III., except in the following classes:—

4. Domestic services—diminution..	39,229
7. Agriculture—diminution	158,472
8. Fishing—diminution	3,717
18. Textile fabrics—diminution	57,860
22. General dealers and workers—diminution..................	194,473

The diminution in Class 4 is largely owing to "bad times" in 1901; the decrease in Classes 7 and 18 is serious in its industrial aspect; the decrease in Class 22 is partly owing to greater care in 1901 in bringing persons into definite headings of occupation. It is obvious that the economic interests of the persons engaged in industrial occupations are by no means uniform; and to some extent are opposed. A country where occupations are thus distributed is not a protectionist country. It requires in many respects an abundant importation of goods from abroad, at moderate prices. Between 1891 and 1901 in England and Wales the urban population increased 12·2, and the rural 2·9 per cent.

In 1901 the British Empire comprised "more than one-fifth of the land surface of the globe." The distribution of the population is seen in Diagram II.

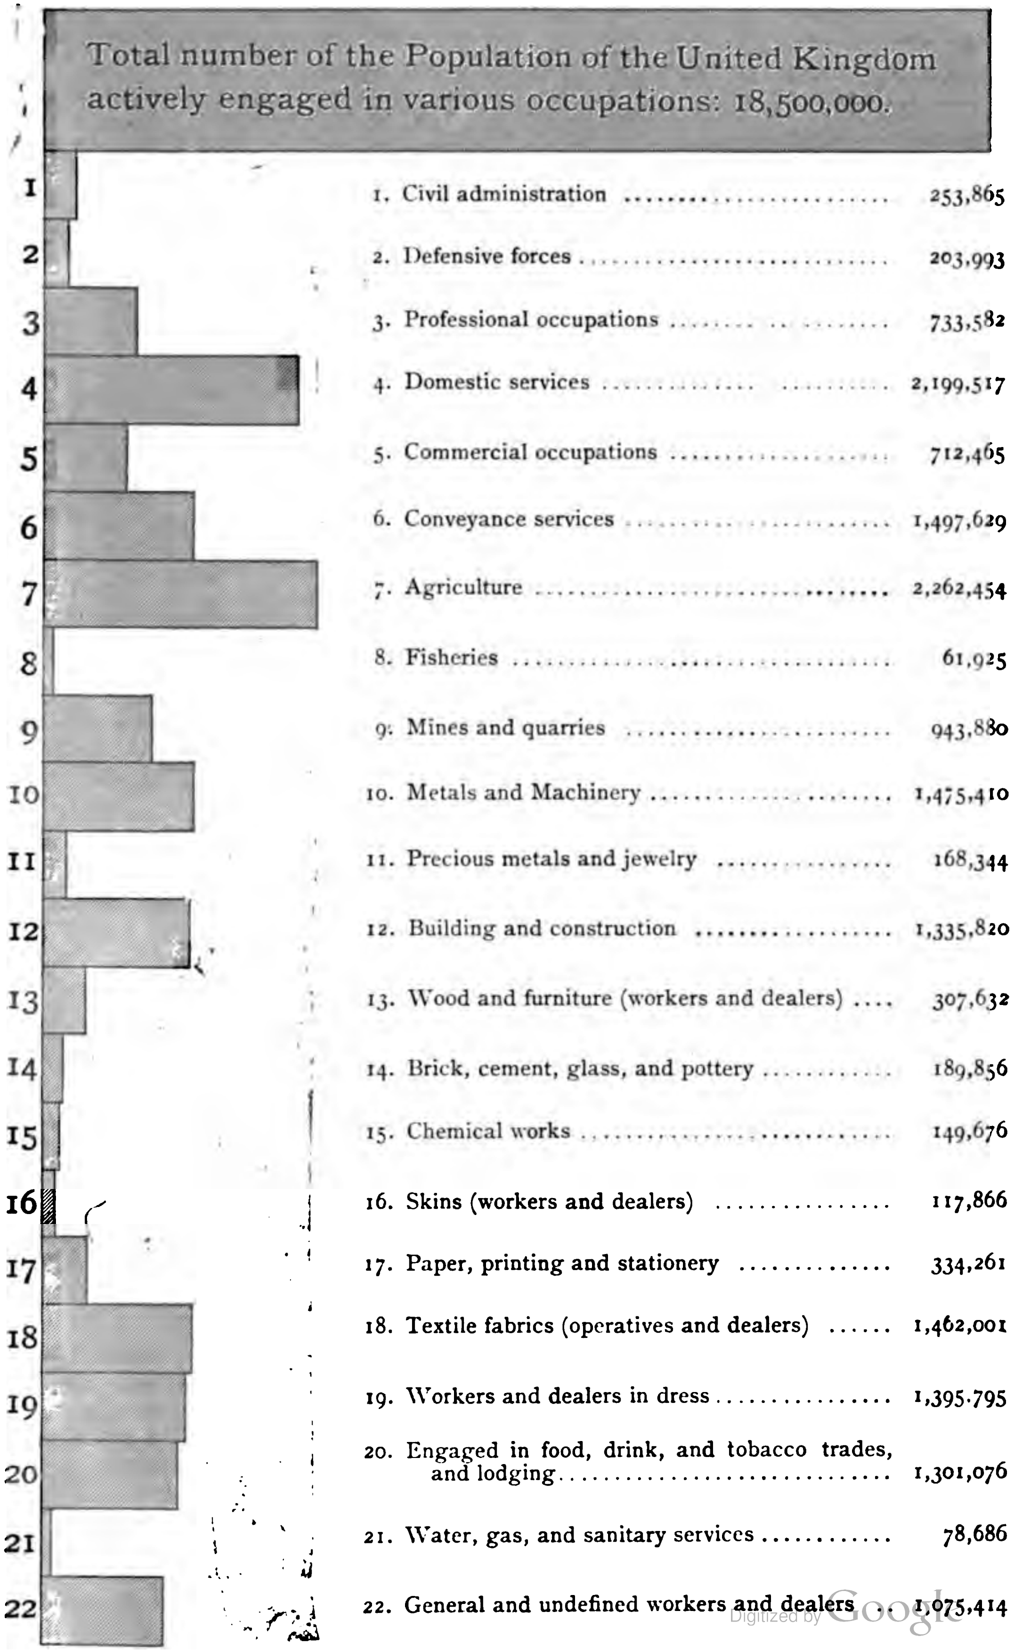
The diagrams show:—First, population of the United Kingdom; secondly, population of the whole Empire; and thirdly, occupations of the people. The Board of Trade statistical charts prepared for the St. Louis Exhibition, which are in the Society's library, show fluctuations of employment, wages, and prices; and that moderate Customs' duties do not increase the



II.—Population of the British Empire, which comprises "more than one-fifth of the land surface of the globe," with a population of 400,000,000: Census Report, 1901.

cost of commodities. Three preliminary conclusions result from this survey of the United Kingdom and the Empire:—

1. Fiscal policy should not have exclusive



III.—Occupations of the People according to the Census of 1901.

reference to the United Kingdom: the interests of the whole Empire require attention.

2. *Industrial* occupation and work give direct employment to a relatively small portion of the people of the United Kingdom.

3. The United Kingdom has become, to a large extent, a residential country.

These facts enable us to dispose of two assertions on which stress has been laid in the fiscal controversy. One speaker asserted that "probably 7-10ths of the people are producers first of all, and can only be consumers to the extent they produce." Another speaker asserted that "the working men were 7-10ths of the entire nation." In the light of the information now afforded these statements carry with them their refutation.

Turning next to main considerations bearing upon the several divisions of commerce—

1. *The Home Trade*.—There are no statistics which show the home trade of different countries. It will be evident that this must be the case; there are no means of measuring the consumption of commodities. Reference has been made in the measurement of internal trade, to clearing house and railway returns, bank deposits, and income-tax yields, but these figures do not supply an exact criterion of the amount and value of the internal trade. Sir Robert Giffen says ("Economic Inquiries and Studies," vol. 2, p. 405)*:—

"The bulk of the exchanges in every community is, and must be, not between the community and the outside world, but among the members of the community themselves. The main quantity of business is in fact always local. The members of the community mainly work for each other, and exchange services with each other."

The second great division of commerce, the *export trade*, is closely connected with the main questions which are comprised in the fiscal discussion. As, however, the trade relations of foreign countries must be considered in connection with our export trade, this division of the general subject will be more conveniently treated in a separate section of this paper.

The carrying trade, the third branch of commerce, which is of very great importance to British interests, resembles the home trade in the absence of a definite measurement of its extent and value. The Board of Trade Bluebook, No. 1761, of 1903, p. 101, estimates the aggregate gross earnings of British shipping at "about 90 millions." It is not possible now to attempt to apportion the earnings of the shipping trade, and the remarks on the subject must be limited to the traffic more directly concerned with the fiscal question — namely, the carrying and transit trade. This is a lucrative branch of shipping business. There is, however, obviously no special reason why it must necessarily be conducted at British ports. The course of this traffic depends largely on trade customs and habits, and on convenience. Freedom from irksome formalities, and facilities in financial transactions, are the leading facts which at the present time secure a very large transhipment and call business at British ports. The circumstances of this traffic are grounds for caution in fiscal changes.

Financial operations must also be borne in mind. London is now the banking centre of the world. Financiers of almost all countries keep money in London. It is often the easiest and cheapest course, in transacting international business, for a merchant in country A to make a payment due in country B by giving his creditor in country B a bill of exchange on London, instead of effecting payment by a direct remittance. Steadiness in the Bank of England rate, and in the value of the London sterling bill of exchange, are very important factors in the financial mecanism of the world; and for British interests. At the present time the international money market determines, to a large extent, the commercial and financial prosperity, and the *status* of nations. Business follows capital, credit, and capacity; it is often dependent upon banking houses which aid business transactions, not only with money advances, but equally by their ability, experience, and knowledge. The adequate supply of cheap money, and the growth of banking deposits, render funds available for profitable use at home and abroad. Local extravagance and bad finance have latterly injured our home investments and trade, and have diminished national wealth. *The Times* financial supplement of September 12th, 1904, contains an important statement relative to profitable investment abroad. It is to be remembered, however, that while foreign investments form an important part of the financial operations of this age, they are not reproductive for our national resources in the same way as home business. Their permanence and stability are also less secure. Accordingly, on financial as well as on other grounds, caution is needed in regard to fiscal changes in the United Kingdom.

* Subsequent quotations are taken from this volume, unless another work of Sir Robert Giffen is mentioned.

The foreign trade in its relation to the fiscal question was considered at some length in the paper of December 2nd, 1903. The Board of Trade Blue-book, No. 2337 of 1904, pp. 379-94, contains fresh information, which renders it necessary to advert again, as briefly as possible, to this part of the subject. This second Blue-book, on British and Foreign Trade and Industrial Conditions, fully maintains the high standard of the first volume. The completeness and scope of the information afforded, and the combined fairness and reticence with which controversial topics are treated, add to the public service which the Board of Trade render by these publications. The division (established in the Blue-book of 1903) of countries designated as "Protected" and "other markets" is maintained in the new volume, and completed to date.

The estimated average *ad valorem* equivalent of the import duties levied by the under-mentioned foreign countries and British possessions on the principal manufactures imported from the United Kingdom:—

	Per cent.		Per cent.
Russia	131	Roumania	14
Spain	76	Belgium	13
United States ..	73	Norway	12
Portugal	71	New Zealand ..	9
Austria-Hungary ..	35	Japan	9
France	34	Turkey	8
Argentine Republic	28	Switzerland ..	7
Italy	27	Australia	6
Germany	25	South African Customs Union (Preferential Tariff)	6
Sweden	23	China	5
Greece	19	Holland	3
Denmark	18	British India ..	3
Canada (Preferential Tariff)	17		

While it is not claimed that these calculations are wholly satisfactory, it may at least be stated with some confidence that the countries and colonies included in the inquiry should be ranged approximately in the above order, as regards the comparative level of their import duties on the principal manufactures which are exported from the United Kingdom.

It would not, however, be justifiable to conclude from the above figures that the Customs tariffs of the various countries are ranged in the same order as regards their comparative protective efficiency. The protective effect of a tariff is not necessarily proportionate to the average level of the duties, but also depends on many other factors, such as the comparatively advanced or backward state of the home industries protected. A 25 per cent. duty in Germany may give as complete protection to a native industry as a 100 per cent. duty in a more backward country. A high duty may have no protective effect, if the article to which it applies happens not to be manufactured in the country in question. (P. 292.)

Passing over tabular statements in this Blue-book, which are of great interest and importance, the facts bearing upon our enquiries are—(1) that the United Kingdom is the most important market for the products of France, Germany, and the United States; (2) that the export trade of these three countries has experienced less impediment from the tariffs of other protectionist countries than has been the case with the export trade of the United Kingdom; (3) that these tariffs place more impediment in the way of British exports, which consist mostly of manufactures, than of exports from countries in which manufactures form a smaller element; (4) as regards trade to "identical neutral," as well as the "protected," markets, "the rate of increase is seen to be greatest in the case of the United States, followed by Germany, the United Kingdom, and France." There is, however, another point to be borne in mind, tariffs are not the only reason which has diminished British trade or prevented its growth. Improvements of machinery, and the extended use of steam power, as well as sound technical education, have, during the last half century, equalised the industrial efficiency of manufacturing countries. Skilled operatives, managers and teachers, are now established there, and the leading firms are controlled by their founders or immediate successors, and not by more distant followers. New appliances and improved routes of communication favour the productions of foreign countries which now largely supply their own wants, and offer in neutral markets goods suited to the needs and fashions of the people—often more appropriate than British goods. There are no grounds for anticipating that protectionist nations will, of their own accord, alter their fiscal systems or customs regulations in order to facilitate British trade. If we wish alterations for this purpose, we must, ourselves, take action. The principal openings for real expansion in our export trade are to be found in neutral and Colonial markets. It is, therefore, a matter of primary importance to our manufacturing population, as well as to our national interests, that the actual conditions of these markets shall be fairly and dispassionately made known. The "Statistical Abstract of the British Empire," published this month, is another of the very instructive compilations issued by the Board of Trade, the study of which is essential for obtaining adequate information respecting Colonial trade.

The values of imports and exports taken

alone do not afford complete evidence as to the amount of trade. The quantities of goods must likewise be considered. The limits, and the primary object, of this paper make it necessary to omit the statistics on which the examination of this part of the subject is based. The result proves that the increase in the value of exports in 1904 over 1903—£64,081,514 as compared with £55,267,497—is to be attributed to enhancement of price, and not to an increase of trade. The assertion that a large increase of trade took place in 1904 is erroneous. As regards the general question often referred to in fiscal discussions of the excess of imports over exports, Mr. Smart, in "The Return to Protection," reckons (p. 41), that the values of the total imports of the commercial nations of the world is approximately £2,516,000,000, and of their exports £2,292,000,000. There is thus a debit balance in the trade of the world of about £224,000,000. Consequently, the nations of the world are either losing instead of gaining by their trade, which is contrary to fact; or else this apparent deficit is balanced by other payments—the largest items, in our case, being earnings of the shipping trade, and income from external investments.

The industrial position of the country is directly connected with the trade questions adverted to in the preceding sections of this paper. It is very fully set forth in the memoranda and statistics relative to economic matters contained in the Board of Trade Bluebook, No. 2337, of 1904. An admirable summary is published in the Society's *Journal* for the 24th of February, 1905. It is sufficient for the purposes of this paper to refer to the article on the "Distribution of the World's Industrial Population" contained in that number of the *Journal*, and to add the following Tables, giving this information from the German standpoint. *Industrie Zeitung* of Berlin, in October, 1904 (translation in the *St. James's Gazette* of October 26), stated as follows the proportion of persons employed in the three great subdivisions of employment:—

1. *Agriculture, Horticulture, and Forestry.*

Italy	59·4	United States	35·9
Hungary	58 6	Holland	30·7
Austria	58·2	Belgium	21·1
France	44·3	Scotland	12·0
Germany	37·5	England and Wales	8·0

Russia does not appear in this list; but would probably come first in this category.

2. *Manufactures and Mining.*

Scotland	60·4	Germany	37·4
England and Wales	58·3	France	33·6

Belgium, Holland, and Switzerland—more than one-third of the working population are so employed.

United States .... 24·1

3. *Commerce and Transportation.*

Holland	17·2	Germany	10·6
United States	16·3	France	9·4
England	13·0		

The Fiscal Outlook in Foreign Countries.

There does not seem to have been any changes in the Customs tariffs of foreign countries in 1904, detrimental to Britain; but the outlook in the near future is unfavourable. The new German tariff, which will come into force on the 1st of March, 1906, accentuates the recent commercial policy of the German Empire, and will be the controlling influence in central Europe during the next twelve years. According to newspaper reports, the French Government are now making an enquiry as to the probable effects of this action upon French trade. The commercial advisory committee of the Board of Trade reported on this new tariff in the following terms:—

"It is proposed to increase the German import duties on the great mass of articles in which the trade of this country is interested by rates varying from 25 to 100 per cent. and over. In some instances, as in the case of various classes of machinery, the percentage increases on present rates reach almost startling proportions. Moreover, the statement, as will be seen, mentions a number of articles which, although previously free of duty, are now to be charged burdensome rates. And it has to be added that where the proposed increases in duties fall short of the level of 25 per cent., the articles are, in most cases, already supporting as heavy Customs charges as they can well bear. To attempt to particularise in respect of the rates for individual articles would virtually involve a recapitulation of the whole statement which, we think, should be placed in its entirety before the German Government with a view to obtain reductions in the proposed rates of duty on the articles included in it.

"But it is not alone in respect of increased duties that the new tariff is viewed with disfavour by our commercial and industrial community. It has to be pointed out that it proposes to enact an extensive sub-division of some of the more important categories of the existing tariff, and that this, in actual practicc, will require intricate calculations, greatly increase the labour of German importers and Customs officials, and unduly impede the course of trade, besides giving occasion for innumerable disputes between importers and the authorities."

On the 30th January, new commercial treaties between Germany and Austria-Hungary, Belgium, Italy, Roumania, Russia, Servia, and Switzerland, were published at Berlin. *The Times* correspondent there, on that date, said that under these treaties the Customs tariffs of these countries, respectively, will also be raised. The commercial treaty system of 1905 will thus possess conditions of permanency. It would seem that the German Government have disregarded the representations of British commercial bodies, and of our Government, asking for some modification of the new arrangements. *The Times* correspondent makes the following remarks respecting the bearing of the new duties in Germany, on British trade:—

"The new industrial duties are of the greatest interest to England. On the whole they represent for the textile industry a considerable increase in protection for the German producer, especially as regards wool and cotton. In general, it is the finished products rather than yarns, which are subjected to heavier duties, amounting in some cases to an increase of 30 to 50 per cent. In the case of flax and jute yarns there is very little difference, and in some cases there even appears to be a reduction. For leather goods there is a large increase, confined to finished articles, and amounting in the case of shoes to a difference of from 7 to 12 per cent. on the present duties. In the case of paper and paper goods it is difficult to institute a comparison, since the different categories of these goods are arranged on a new system. On the whole, where there were formerly two or more sets of duties according to quality or finish, a comprehensive duty is now imposed, which is higher than the lowest scale and in some cases as high as the highest. Under certain headings there is a considerable increase. In the case of iron goods the new classification is so elaborate that a comparison could only be instituted by experts. Indeed, it is a feature of the new treaties that more effective protection for German industries is frequently secured by minute specification and by the imposition of higher duties only in cases where foreign competition has already made itself felt.

"Under the heading of machinery the system of admitting certain important materials for shipbuilding without duty is maintained, as in the case of ships' engines and boilers. On the other hand, industrial machinery and mechanical tools, which Germany now manufactures with considerable success, are subjected to heavier duties. Motor carriages and bicycles will be charged for according to weight on a scale ranging from 100 marks (£5) to 15 marks (15s.) per 100 kilogrammes. Bicycles and finished sections of bicycles will be charged 100 marks (£5) per 100 kilogrammes.

"It is a matter of urgent necessity that the new German industrial duties should be subjected to careful scrutiny in England, with a view to seeing whether they can be accepted, or whether protest, and eventually retaliation, would be advisable. The absence of a treaty of commerce between Great Britain and Germany gives the British Government a free hand in this regard."

The fiscal policy of Germany, and of other countries, is directed to secure for home manufacturers the command and supply of the home market. The people of the country and the Legislature are well aware that *high* Customs duties increase prices at home. But this policy increases shipping and trade business, and it secures continuous employment for the working classes. The continuous running of factories and a maximum output also reduce the cost of production. Whatever opinion may be entertained respecting the merits or demerits of the protectionist policy adopted in Germany in 1879, since then, and especially since the conclusion of German tariff treaties, great and rapid progress has taken place in most branches of manufactures and commerce. The Government act upon this policy as part of their plans for the development of national industry and their position among nations. The proceedings of the German Government in Turkey are an object-lesson in this respect, and have been summed up in *The Times* in these words:—

"In 1882 German exports and imports to and from Turkey were 5,900,000 and 1,200,000 marks respectively. By a gradual and steady progression they had risen to 43,300,000 and 36,600,000 marks in the next twenty years. And German interests—even financial interests—in Turkey are not all, there is good reason to believe, in the hands of individuals or of corporations supported by the State. In at least one important enterprise—the Constanza-Constantinople Cable Company—it is reported that more than half the shares are held by the Imperial Ministry of Posts and Telegraphs." (Feb. 9th, 1905.)

The policy of the Dingley tariff in the United States has been well explained in a recent letter of Mr. Shaw, the Secretary of State:—

"If I understand the Dingley law correctly, it, in effect, says to the American producer, artisan, and farmer, You shall have protection within the American market. Whoever invades the American market must pay duty upon the articles with which he makes invasion. But the same law says to the American exporter, If you will employ American labour, pay American wages, you shall have every possible advantage in your effort to reach foreign markets. You shall have free iron, free lead, free wool, free hides, free wheat, free everything except labour. There must be neither contract labour nor coolie labour employed, even in the manufacture of

goods for export. American wages must be paid so that the American labourer shall be able to put a roof over his family, unpatched clothes upon his children, and have meat upon his table at least once each day." (*Times* Commercial Supplement, Feb. 13th.)

Recently, a new phase in the development of industrial business has taken place. For several years past, foreign manufacturers have acted together in distant markets and in exhibitions. This was joint action or *collectivité*. The idea, carried into general business, became combinations of financiers or manufacturers formed under the designation of kartells or trusts. All trade demands are somewhat uncertain, and when supplies exceed their demands, the existence of a kartell or trust enables manufacturers to dispose of their products by mutual agreement, without competition between themselves, and without curtailing employment. Rightly acted upon, such combinations may be useful, both to principals and operatives.

Serious abuses, however, have arisen from combinations of capitalists and manufacturers, directed against either the public generally, or their own workpeople, especially when they withhold supplies of goods from the market. President Roosevelt has pointed out the pernicious effects of the use of vast wealth, exerted in combined action, to build great power with the object of controlling the Legislature for the benefit of individual capitalists, and to further their aims. This action of trusts and kartells is the worst outcome of a protectionist system. These combinations, in their operations in foreign markets, confer insidious temporary advantages. For example, in the present conditions of industrial enterprises, the British market being open, the foreign exporter can rely on it for taking his surplus stocks—a very important point in trade—with safe and early payment, on terms more or less advantageous to the exporter. The buyers of these particular goods may benefit at the time, yet such sales brlng uncertainty into commercial business, and endanger English manufactures. Liability to an influx of competing goods on these terms paralyses the power of managers and principals to carry on works; while loss of employment and bitter suffering befall the best classes of workmen and their families. A general sense of insecurity prevails. Then, as to the entry of British capitalists into protected areas, it is said that "for every £100,000 that the protectionist policy causes to be sent from England to be invested in American factories, it probably keeps away at least £1,000,000 that would otherwise have been sent there to be invested in railways and agriculture" ("Riddle of the Tariff," p. 32). But this statement is not an argument. The £100,000 investment is assumed to be a fact; the £1,000,000 is only stated "probably," a mere hypothesis.

Some persons seem to deny the fact of the dumping of foreign goods—*i.e.*, the sale below the normal market rate. Mr. D. A. Thomas, M.P. (whose opinions I have already quoted, and whose valuable paper on the coal trade obtained the Guy medal of the Royal Statistical Society), said at Merthyr on the 4th of December, 1904, "I am prepared to agree with you that some of the want of employment is due to dumping." Mr. Keir Hardie, M.P., said at Dowlais, on the 26th of September, 1904, "that there has been dumping from America and Germany was unquestionable." Mr. Cripps, M.P., in a speech on the 5th of March, 1904, said, "The necessity of some immediate effective action was emphasized by the operation of the economic 'law of surplus,' which in ordinary language had been familiarised under the term 'dumping.'" Mr. Thomas Spittle, of Newport, gave in *The Times* of the 30th of January, 1905, recent instances of the dumping of German goods to the detriment of South Wales industries. It is thus seen that there are at the present times various questions connected with our foreign trade which ought soon to be determined, and which are of very real importance. Outlets are needed for our exports, while, as regards imports, an abundant and cheap supply of goods does not necessarily imply the cheapest supply at abnormal rates owing to exceptional disturbance of the ordinary course of trade.

Certain main subjects directly bearing upon the interests of the United Kingdom have now to be considered—namely, agriculture, including food supplies, and suggested remedial measures; Colonial preferential treatment; taxation generally, and Customs duties.

Agriculture.

The returns of acreage and live stock issued by the Board of Agriculture and Fisheries, enable the following comparison to be made—for the United Kingdom, including the Isle of Man and the Channel Islands—of the position in 1904 with that in 1875.

The acreage of the great crops, were—

	1875.	1904.
Wheat	3,514,088	1,407,618
Barley	2,751,088	2,002,854
Oats	4,176,177	4,351,183
Potatoes	1,431,879	1,200,419
Turnips	2,485,257	1,898,010

The present totals are:—

	Acres.
Arable land..................	18,977,643
Permanent grass	28,693,305
Under crops aud grass	47,670,948

The wheat and barley crops of 1904 were the smallest on record. Some recovery may however be expected in 1905, consequent upon the favourable weather for farming operations in the preceding autumn. It should be again pointed out that figures for isolated years are not conclusive, but simply show the position at these dates. The answer to a question, asked in the House of Commons on the 9th of August, 1904, stated that in 1903 there was a decrease of 2,683,639 acres of land under the plough, and an increase of 3,448,321 acres under permanent pasture as compared with these acreages in 1873. According to the answer to another question at the same date, the approximate percentage of imported wheat in relation to the total supply of the United Kingdom in the five years 1899-1903 was 77½ per cent. It further appears that there is a steady diminution of the population employed in agriculture. The number fell from 1,904,687 in 1851 to 988,350 in 1901 (Blue-book No. 1761, of 1903, p. 362).

The gross assessment on which income-tax was levied in the United Kingdom from the ownership of lands, has fallen between the financial years 1874-5 and 1902-3 from £66,911,453 to £52,162,825 (Inland Revenue Report, 1904, p. 192). In this Return, lands in urban neighbourhoods are reckoned, and values relating to such land have increased. The decrease in the total amount, proves that the depreciation in agricultural districts has been very large. Mr. R. H. Inglis Palgrave, in his paper read before the Royal Statistical Society, on the 21st of February last, estimated that the losses of agriculture in the United Kingdom between the years 1872-77 and 1904, had collectively been about £1,600,000,000—namely, diminution in owners' capital, £1,000,000,000; diminution in farmers' capital, £100,000,000; diminution in farmers' profits, £500,000,000; total, £1,600,000,000. Further, as Dr. Cunningham points out ("The Free Trade Movement," p. 114), "an English farm is a highly complicated product of civilisation, and, if it is disused for a time, or badly used, it deteriorates in every way. The machinery becomes valueless; the buildings go out of repair, and the land itself becomes foul." The English landowners "co-operate actively in the maintenance of farm buildings, and the improvement of the soil." It is further to be observed that income derived from the ownership of land is subject to deductions from which other incomes are exempt. Revenue from land, in addition to income-tax, is subject to charges for the up-keep and maintenance of the property, insurance, tithe, and local expenses, which in the present social conditions a landowner is virtually obliged to defray. If resident on his property, these claims upon the landowner are accentuated; and further, in changing tenants, under new valuations, allowances are granted which are favourable to the tenant to the detriment of the owner. Thus, whereas investments in funds and stocks are liable only to income-tax, the landowners' nominal income is reduced by about one-fourth by reason of the unavoidable deductions above mentioned. The death duties press, in their practical application, more heavily on landed property than on other property. They subtract from the capital of the country, not from income, and, therefore, are a form of taxation which is unsound in principle. In the words of a writer in the *Investors' Review* of October 8, 1904, these receipts of the exchequer have "been sheared off the capital value of the estates assessed. In no sense, therefore, can such moneys be considered revenue." In concluding this survey of the present position of agriculture in the United Kingdom, the case of the farmer and of the labourer must be noticed. The income-tax returns above recorded prove a serious diminution of the capital and profits of owners; and there is reason to believe that in many parts of the kingdom the financial position of a large proportion of the farmers is precarious. In some instances railway arrangements and sales are unfavourable to farming—being regulated to promote traffic from seaports to inland towns, and between large centres of population, rather than to aid the transport of produce from country districts to neighbouring towns.

As regards the labourers, it is to be remembered that in the country, as a general rule, regular full work is not to be obtained throughout the year. Formerly, cottage and miscellaneous industries helped to make up the income of labourer's families. Latterly,

machinery has lessened the number of labourers needed on farms, thatching is discouraged by insurance offices and under new by-laws; ditching, hedging, and weeding are not so cleanly done as in former times, roads are managed from county centres instead of by local action, strangers who rent country houses do not treat villagers with the regard shown for their welfare by landowners who can reside on their property. Recent by-laws apply rigidly to rural tenements regulations framed for town streets, and thus hinder the inprovement and building of cottages. The Duke of Devonshire, in a speech reported in *The Times* of the 6th of December, 1904, said, "Under the existing building by-laws in most parts of the country a cottage for an agricultural labourer could not now be built at a cost of less than £250 or £300, which meant that the rental would be something like £12 or £15 a year." In existing circumstances, an ordinary landlord cannot afford to put up labourers' houses at this cost, nor can an ordinary labourer afford to pay this rental. Steps to promote the construction of suitable cottages at a moderate cost and rental are much to be advocated. Small holdings, and education adapted to country life instead of rigid assimilation to the studies of town schools, are subjects which now receive attention. The Board of Agriculture, by Lord Onslow's personal action, and by the careful and wise methods of the able staff of that department, is doing good work to remedy disabilities with which a government officer can deal. Individual holdings confer a very real interest in the land, and this movement ought to receive encouragment and support. But it does not follow that when a man secures a small holding he will become a farmer and will succeed in his business. Capacity to deal with the business itself is necessary in all cases, and in farming sufficient capital to defray outgoings, and to withstand bad seasons at the beginning of the tenancy, is also necessary. Mr. Eve, K.C., M.P., a landowner and practical farmer, in a speech at Newton Abbot in December, 1904, recognised the fact of agricultural depression, and attributed it to "the exceptional burdens on land, extraordinary competition, and the want of efficient labour." Mr. Eve's opinion, and the facts already stated, hardly bear out the fiscal policy of an eminent member of the House of Commons, put forward in a speech at Southport on the 22nd of January, 1904: "There was lying untaxed a large reservoir from which, he believed, a substantial contribution might be made to fertilise the country at large, and that was the taxation of land." If it is said that this speech was reported in an abbreviated shape, and that land values, and not land, was spoken of, it is sufficient to say here that at a meeting in London on the 20th of January, 1905, Mr. Harold Cox, a leading member of the Cobden Club, who took part in our discussion on the 2nd of December, 1903, moved "that the taxation of land values is unsound in theory and would be disappointing in practice."

The state of things disclosed in this part of the present paper certainly is a national misfortune and is fraught with national dangers. Mr. Lecky, in "Democracy and Liberty," vol. 2, p. 382, pointed out in 1896 "cheap food, it is beginning to be said, does not necessarily mean the very cheapest, and a system under which the greatest and most important of all national industries is almost hopelessly paralysed, under which land is fast falling out of cultivation, and the agricultural population flocking more and more to the congested towns, cannot really be good for the nation."

Our Food Supplies.

Full informaiion on this subject is afforded in the publications of the Board of Agriculture and the Board of Trade. These returns must be studied in order to obtain complete information on the subject. The particulars required for this paper are given in the most convenient shape in Major Craigie's presidential address to the Royal Statistical Society on the 17th of November, 1903. He has done me the favour to bring up the annexed Tables to the end of last year. (See Tables I. and II.)

The percentages of the imports of wheat into the United Kingdom, contributed by different countries, were stated in the following figures in the *Board of Agriculture Journal* for December, 1904. (See Table III., p. 493).

In the answer (published in *The Times* of the 9th of August, 1904) to a Parliamentary question, it is stated approximate percentages of imported wheat in relation to the total supply in the five years, 1899-1903, was 77½ for the United Kingdom, 34 for Germany, and 2 for France. In the case of the meat supply percentages cannot be definitely stated. The subject has been investigated by a committee of the Royal Statistical Society, and there is good reason to think that the average annual supply in the five years, ended May 31, 1903, was approximately in the proportion of 6, home

REMEDIAL MEASURES.

Mr. Chamberlain, in his speech at Welbeck, on the 4th of August, 1904, reported in *The Times* of the following day, repeated his statement that his proposals are "a sort of sketch plan for the purpose of discussion and consideration." It is important, therefore, to bear in mind that the following rates of duties in the case of agriculture suggested for specified foreign produce are not fixed and rigid proposals:—

1. Two shillings on all kinds of corn except maize.

2. "Such a duty on flour as will result in the whole of the milling of wheat being done in this country."

5. Five per cent. on meat, dairy produce, preserved milk, poultry, eggs, vegetables, and fruit.

To enter fully into these several proposals would exceed the time at our disposal, and would be an investigation which more properly belongs to other societies. Remarks must be limited to main questions affecting the wheat, flour and meat proposals, and some general cautions. Sir James Blyth, in a letter which appeared in *The Times* on the 11th of August, 1903, estimated that "a duty on foreign corn sufficient to raise the price of wheat all round by 5s. the quarter, would be equivalent to one half-penny the quartern loaf." Sir Spencer Walpole, in his "History of 25 Years," vol. 2, p. 432, estimates that the 1s. duty on wheat which remained after the repeal of the Corn Laws, was equivalent to 1/8d. on the price of the 4 lb. loaf." These divergent statements require to be investigated, but are beyond the time at our disposal. Taking, however, general conditions of trade, a statement made by Mr. J. Hill, the president of the American Northern Pacific Railway, and the ablest railway manager in the United States, requires attention in the first place. Speaking to the Minnesota Agricultural Society early in 1904 (*The Miller* of April 4, 1904, p. 85), Mr. Hill said, "a tax of 10 cents. on the 180,000,000 bushels you send to England means 18,000,000 dollars, and you may make up your minds here you have got to pay that 18,000,000 dollars or lose the market. You will pay the tax, or you will hold your wheat, or you will need a new market." According to this opinion, the 2s. duty would be defrayed between the American producer, carrier, or merchant, and the whole North American supply, which Mr. Hill holds is controlled by the Manitoba crop, would be placed on the London market as it is at present. Mr. Boyd Kinnear, writing as a practical Scotch farmer in *The Courier* of January 23rd and 30th, 1904, showed that the Argentine, Roumanian, and Russian wheat growers are, from the circumstances of their trade, dependent upon the London market for the disposal of their stocks. Even if, under the new commercial treaty between Russia and Germany, a large proportion of Russian wheat should

go to Germany, it would seem that the Roumanian supply will still come to England; as well as the Argentine stock, which has no other outlet. This new duty will thus not be likely to affect prices in the United Kingdom. The late 1s. duty on wheat did not raise the cost of bread while it was in force, neither was the price of bread lowered when the duty was taken off.

Lord Brassey, who is a staunch free trader, said at the meeting of the Chambers of Commerce at Montreal in 1903, "I do not suggest that 1s. a quarter on corn, or even 2s. would seriously affect the economic condition in England. The poverty of the poorest comes from other causes than an infinitesimal—and I emphasise the word infinitesimal—addition to the price of bread. A low duty on corn may be balanced by remissions of more burdensome taxation."

Mr. Palgrave, in the paper above quoted, said that a duty of 2s. a quarter on foreign wheat, with free importation of colonial wheat, would "have no effect in raising prices here."

2. As regards the proposed duty on flour, a competent authority in the West of England estimates that 2s. per quarter=5·33 pence per 112 lbs. wheat, and that the equivalent charge on the same weight of flour would be 8·2 pence. The *Mark Lane Express* of the 28th of November, 1904, stated that the Statistical Department of the Customs "reckon 4,800 lbs. of imported (not English) wheat to yield 3,456 lbs. of flour." . . . "Our estimate would have been from 3,552 lbs. to 3,600 lbs." This point would also be a matter for enquiry. As regards the proposal that the duty on corn should be such as to cause the milling of wheat to be wholly done in this country, there is much to be said in favour of encouragement to milling, both in itself, and because an abundance and cheap supply of wheat offals would extend the industry of the manufacture of "compound cake," a most important cattle food. But I entertain doubts whether our present works as now equipped, are capable of doing the entire wheat milling for our markets. As things now stand, it seems possible that this rate of duty on flour would raise the price of bread; and a charge equivalent to 2s. per quarter on wheat would therefore appear to be the preferable plan.

3. The general conditions adverted to are connected with the circumstances of particular trades. Duties might be levied in the case of concentrated businesses—that is to say businesses which are carried on by a limited number of persons, in a limited number of localities and buildings, with much less disturbance of trading relations, and less pressure, than if duties were levied on all agricultural products. Such duties may be logically correct in a scientific tariff. I doubt, hwever, whether farmers attach much importance to them; and public opinion would probably hold that the benefit to be attained would not be commensurate with the inconvenience thereby occasioned. We must beware lest an unfounded allegation of the artificial raising of prices, or plausible misrepresentation on the subject, should provoke popular discontent, render government difficult, and injure the State.

The myth of the big and little loaf is an "object-lesson" in this respect. The thing has not, and cannot have, existence. It is a mere fiction, and yet it is seriously alleged and excites popular feeling. The Bread Act of 1822 and 1836, and the Weights Act of 1878, require bread to be sold by weight. Under these Acts of Parliament, household bread is sold in loaves of uniform weight, and practically therefore of uniform size. There is no big and little loaf, nor can there be. The cry is a survival. The legislation relative to bread, previous to the Acts of 1822 for London, and of 1836 for the country generally, fixed the price of bread. A quarter of flour was reckoned to produce 80 quartern loaves. In practice, however, with the varying price of flour, the size of the loaf varied somewhat; and so in those times there were big and small loaves. This state of things has passed away long ago. This cry has no meaning now; but it is a striking instance of an unfounded argument; and a warning against proceedings which might in a similar manner be misrepresented.

It may be asked how could fiscal changes within the limits above indicated be effected; and what would be the benefit to the landowner, the farmer, and the labourer. The gain to the landowner would be indirect, by means chiefly of the improved conditions which his tenants will obtain. The gain to the farmer would be brought about by more stable and secure market conditions. The gain to the labourer would be the more continuous and regular employment upon which, in these altered circumstances, he could rely. As regards the means whereby these changes might be effected, the first step would be a careful inquiry into these questions, conducted by competent and impartial persons. The aim would be to promote the welfare of the United Kingdom, and to draw closer the rela-

tions between the different portions of the British dominions. The policy of fiscal changes, involving the taxation of food within the limited range of commodities, and at the low rates of duty now suggested, is apt to be misapprehended. The advantages of the scheme in itself, and the accompanying "relief of more burdensome taxation" are apt to be overlooked. As Mr. Balfour said at Manchester on the 11th of January, 1904, "there is no hope of bringing that policy to a successful issue unless you carry with you the conscience, the intellect, and the convictions of the populations concerned."

PREFERENTIAL TREATMENT BETWEEN THE UNITED KINGDOM AND BRITISH POSSESSIONS.

Correspondence published by the India and Colonial Offices (Parliamentary Papers Nos. 1,931 and 2,326 of 1904), affords authentic information on this part of the fiscal question. The report of the India Government is dated Simla, October 22nd, 1903. The state of trade between India and different countries is fully examined. Sir Edward Law, the Financial Adviser of the Government of India, expresses the opinion that it is "more in Indian interests to leave matters as they are, than to embark on a new policy, unless, by its adoption, very great advantages could be obtained by preferential discrimination in favour of our exports to the United Kingdom and British Colonies and Possessions." The position taken by the Government of India is thus summed up: "All that we seek is that we shall not be pledged in advance to accord equal treatment to the imports of all countries alike, irrespective of whether they penalise our exports or not. And we hope that the mere announcement that our hands are free will, of itself, suffice to maintain us in the enjoyment of that considerable measure of free exchange which we already possess, and from time to time even to extend it."

The case as regards the Colonies, stated shortly, is that Canada grants a reduction of 33⅓ per cent. in the amount of Customs duties levied on the products of the United Kingdom; that New Zealand admits specified goods free; and that South Africa admits free goods included in the schedule of 2½ per cent. *ad valorem* duties, and a rebate of 25 per cent. on other duties. The Legislative Council of Victoria has passed a resolution in favour of consulting the other colonies of Australasia relative to a proposed "conference between the Colonial Office and responsible Ministers representing the various colonies." This subject was before the Parliament of the Commonwealth of Australia in the session of 1904, but the debate was not concluded. The House of Assembly of Bermuda has appointed a committee to consider a report on the changes of tariff necessary to admit of a preferential rate on British goods. The House of Assembly and the Legislative Council of Barbadoes, and the Legislative Council of Dominica, have passed resolutions in favour of preferential tariffs. The action taken in Canada, New Zealand, and South Africa is definite and independent action. There is no "offer" in it, or in the expressions of other colonies; but there is "expectation" in Canada, New Zealand, and South Africa, that these grants, which go beyond an "offer," will be reciprocated by the United Kingdom. The Australian and other Legislatures await our decision. It has been stated that the Colonial trade is the expanding branch of the external trade of the United Kingdom. It differs from foreign trade in being under wholly British influences—being under the control of our own, and our Colonial, Governments. The commercial, as well as the social, relations of the different divisions of the Empire are questions of intimate mutual concern. Canada is the leading factor. Sir Wilfred Laurier, speaking on the 12th of October last, said "We have a place in our hearts for British preference, but the feeling is not mutual yet. . . . . The answer is no longer in our hands, but in those of the English people. With good will and a determination to give common ground an understanding can be reached." The *Citizen* newspaper of Ottawa on the 13th of September, 1904, wrote:—"The United States is ready to do business right off. . . . . It is to be hoped that the British people will not linger too long. They have lost half the continent through being too slow to recognise the signs of the times, and they will be in luck if history does not repeat itself." A feeling exists in the United States in favour of a reciprocity league with Canada. There is no active agitation in this direction on either side of the North American border at present; but if this country refuses to enter into closer commercial relations with the Dominion, then the trade interests of the Dominion with the Mother Country and the United States respectively will be transposed. The present home connecting ties will be loosened, and in a few

years an altered position of affairs will exist. There is however, a difference, and possibly several steps, between an abrupt refusal to entertain the question of preferential treatment and the realisation of a practical policy. Various details have to be settled, and certain difficulties must be overcome. Australia is a doubtful element, but would probably fall into line. The instability of parties in Australia, the proceedings in regard to the mail contract, British labour, and the British New Guinea claims, cause doubt to be felt with respect to Australia. The aggressive attitude of foreign governments is likely, however, in some instances, to compel British colonies to decide soon whether they can rely on British support, or whether they will come within the sphere of these foreign interests. In such circumstances a sympathetic attitude on the part of the Mother Country will be of the greatest value. The only alternative to save abrupt refusal of closer commercial union, and in opposition to the preferential policy, that I am aware of, is the scheme sketched by Sir Robert Giffen. In "Economic Inquiries and Studies," vol. 2, p. 399-404, Sir Robert Giffen indicates ways in which "union may be promoted with mutual advantage to all parts of the empire, including the further advantage of accelerating a closer political union."

1. The colonies should adopt a free-trade policy. 2. A postal, telegraph, and communication union, independent of, though not opposing, postal and telegraph agreements with foreign countries. 3. Monetary union as far as practicable. 4. Identical legislation in each part as to the various subjects of commercial law. 5. Common negotiation of all commercial treaties, so that no treaty could be made that did not bind the whole Empire on one side, and did not bind each foreign Government to the whole Empire on the other side.

Points 2, 3, and 4 are matters to be dismissed in a colonial conference. As regards the first point, the economic and social conditions of newly-settled countries preclude the adoption of a free trade policy. In particular ports, such as Hong Kong, Singapore, and Penang, which are *entrepôts* and ports of call, Customs duties may be dispensed with, but in a large district or country no scheme has yet been devised by which the revenue required can be raised wholly by direct taxation. As regards the last point, the negotiation of commercial treaties, the requirements of different parts of the Empire, and the views of their administration are not identical. To bring them all into line is difficult and takes time. Negotiations do not depend on the wishes of one party only—especially when the fiscal policy of one party makes it weak in negotiation. The interests of the United Kingdom, and the attitude of foreign Powers, render long delays in the negotiation of commercial treaties unadvisable. The principle of the present practice is preferable, namely, that the stipulation relative to colonies shall enable them to decide whether they will, or will not, be bound by the treaty; and that special arguments shall be made with foreign Powers to provide for the trade requirements of particular colonies. His Majesty's Government should not engage to grant foreign Powers, either in this country or in any colony, fiscal treatment the same as may be established between different portions of the British Empire. It cannot be too clearly laid down that this subject is no concern of foreign Powers. Differential treatment by such Powers, on the ground that preferential arrangements are adopted in British territories, such as German action towards Canada, requires, for the safety of the Empire, prompt and decisive counteraction.

Lord Avebury, writing in support of our present fiscal system (*Free Trade*, p. 153), says that Canada and New Zealand have made "a substantial difference" in favour of our goods in their Customs tariff, and expresses a hope "that other colonies will follow," and proceeds, "we gladly recognise the spirit in which these advantages are offered, and they will no doubt benefit our commerce." But, as Sir Wilfred Laurier said, the feeling is not yet mutual; corresponding action on the part of the Mother Country is awaited.

It may be asked, what is the estimated gain and result of the system of Colonial preference, supposing it is adopted. The only answer that can now be given is that of the writer in the *Edinburgh Review* of October, 1904, namely, that this gain and result cannot be measured until the nature and extent of Colonial proposals are known. They can only become known by means of a Colonial conference, empowered to discuss the whole subject freely and fully. Mr. Goldwin Smith has well remarked we must not expect to frame a fiscal system equally suitable to the whole number of British communities scattered over the globe, and differing widely in their commercial circumstances. Yet it does not seem to be at all impracticable to arrive at an agreement upon general principles, adapted

to their varying economic conditions. The object in view is a great aim in the welfare of mankind. Mr. Henry Norman, M.P. ("The People and Politics of the Far East," p. 601,), sums up his travels:—"It has been my fortune to see at close quarters almost all the civilised nations of the world, and most of the great colonies, and the result is that I believe in Englishmen above all other men, and in British rule above all other rule. Therefore the British Empire is to me the most important impersonal consideration on earth, and the transmission to our heirs of the legacy of our fathers the greatest responsibility."

Taxation.

Taxation really underlies the fiscal controversy. The point to be determined is the kind and extent of taxation which is most suitable to existing circumstances. Many considerations have to be kept in view in the decision come to; and if the Custom s duties charged, and the commodities on which they are assessed, are so arranged as to yield the maximum of revenue, with the least burden and difficulty in collection, it is truly a revenue tariff. Incidental protective tendencies and effect will thus be due to fiscal exigencies, rather than to a policy exclusively directed to bear upon industry and trade. In this manner, Mr. Gladstone's aim may be accomplished, that benefit is conferred on the working classes chiefly by operating "upon the articles that give the maximum of employment." In proceeding now to submit for consideration the national balance-sheet, the "Statistical Abstract" for 1904, page 1, contains the official statement of revenue and expenditure.

1903-4	144,270,000	141,545,579	— 2,724,421	148,442,446	146,961,136	— 1,481,310	— 5,415,657

It is only by means of a conference of authorised representatives of the Colonies that their wants and offers can be known. The words of irresponsible persons, and especially of members of opposition parties, to whomsoever spoken, are of little weight, and are certainly not "evidence" in the question.*

The outlook as regards the revenue in the current financial year 1904-5 indicates a probable surplus, with improved prospects for the ensuing year.

Customs duties in the years 1889-90—1903-4 stand:—

* The above section of the paper does not discuss the objections urged against Colonial preferential treatment on the alleged ground of its unfavourable effects in former years. The reasons for this omission are—(1) that this adverse aspect of the case appears to be overstated; and (2) however this may be, the present circumstances and proposals are so entirely different from the previous condition of affairs that these objections are irrelevant to the suggestions submitted in this paper.

Other totals in 1889-90 and in 1903-4 were :—Excise, £24,133,232, rising to £31,546,836; stamps, £6,157,154, rising to £7,394,039; Post Office services, £3,524,003, rising to £4,369,067.

A further review of taxation, taken from Sir Robert Giffin's "Financial Retrospect" in the "Journal of the Royal Statistical Society" for March, 1902, a paper which fully explains the course of taxation during the last 40 years, shows the following results. These figures have been brought up to date by Mr. Mackenzie, the librarian of that society, who has afforded me other assistance :—

Decennial periods.	Amounts of taxation: million £. Imposed or increased.	Repealed or reduced.
1861-1871	4 8	26 7
1871-1881	21·0	20·3
1881-1891	12·2	18·8
1891-1901	24·6	5·2
Financial years.		
1901-1902	11·5	—
1902-1903	5·4	—
1903-1904	—	12·8
1904-1905 (estimate)	4·55	—
	83·65	83·80

It thus appears that, notwithstanding the gradual increase of civil expenditure and the recent war charges, Imperial taxation in the period 1861-1904 remains practically unchanged.

The National Debt. funded and unfunded, was in 1861 £823,328,622; in 1901 £762,629,776.

The population of the United Kingdom was in 1861 26,709,456; in 1901 41,458,721.

There has been a large accumulation of capital since 1861—the precise amount cannot be discussed within our limits. Put in another form, Sir Robert Giffen in an article in the *Contemporary Review*, January, 1905, states the case thus :—

Expenditure.

	Forty years ago.	Present time.
Imperial	£70,000,000	£140,000,000
Local	£36,000,000	£144,000,000

Revenue.

Imperial	£70,000,000	£140,000,000
Local	£35,000,000	£105,000,000

The actual burden of imperial taxation cannot, however, be said to have increased during this period, owing to the parallel increase of the national resources. But an unequal proportion of the revenue derived from "taxes" is now contributed by the property and income-tax payers. Exchequer receipts in the year ended March 31st, 1904, were :—

	Millions.	Percentage.
Property and income tax ..	30·8	22
Other sources	110·7	78
	141·5	100

In comparison with taxes, properly so-called :—

	Millions.	Percentage.
Property and income tax ..	30·8	26
Other taxes	88·6	74
	119·4	100

Whereas 40 years ago the percentage to the total receipts was 15 instead of 22.

Accordingly, the income tax is an unduly exclusive charge upon a limited number of the population; and, in its incidence, has become oppressive, at the rates levied in recent years. The incidence of certain other duties and taxes is also above the rates which should properly be levied under normal national conditions. Taxes should be below the rate which will yield the largest revenue properly chargeable in order to permit of ready increase of revenue in case

of need. The burden imposed upon the people in recent years has been in local expenditure, a subject outside the scope of this paper. The national balance-sheet in itself suggests inquiry into our present fiscal policy. There are indications that the revenue is losing in some respects its elasticity and ascending force; and that, at an early date, some readjustment of taxation will be advisable. As regards the future of national requirements and expenditure, we must refer again to Sir Robert Giffen's writings. In a paper on "The Wealth of the Empire and how it should be used" ("Journal of the Royal Statistical Society," September, 1903), he remarks:—

(1.) That the expenditure of 100 millions for internal government, for that is what the figures come to, if we except the Post Office, where the expenditure is largely productive, is not an enormous amount for a community with an income of 1,570 millions, being little more than 6 per cent.

(2.) As regards the military and naval expenditure, "The question of the amount to be spent is for the most part hardly optional. Defences of a certain quality and extent have to be found if the community is not to go under, and the question how much these should cost is really one for experts. Nor does a sum of 70 millions appear overwhelmingly burdensome..... the proportion of 70 millions to the aggregate annual income of the people being about 4 per cent., and to the accumulated wealth .... about 0·47, not a heavy rate of insurance. A comparison of the great military nations—Russia, Germany, and France—also shows that we spend less, and not more, in proportion to means. For these and the like reasons, the conclusion seems unavoidable that there is no real prospect of economy in armaments, and that an increase beyond the present amount is not improbable. .... The nature of our Government tends to cause neglect of these matters. At a given moment we are more likely to be underarmed than overarmed."

The reflection on this expenditure is that the burden is universal, and may possibly bring about some international agreement; but in our case, as matters stand, if our national safety is to be maintained, no large reduction of defensive expenditure can be looked for. Careful and efficient administration may effect economies of limited extent.

(3) Sir Robert Giffen advocates an increase of expenditure on behalf of education in its different branches.

This brief survey respecting Imperial taxation leads to the conclusions that, while it is not unduly burdensome, some readjustment should be considered, and that promises of large reductions are, in Goethe's phrase, an instance of "assertive ignorance," which is one of the most perilous guides in human affairs.

Differential Duties.

In offering some observations on this part of the fiscal question, it is necessary to advert in the first place to a remarkable Parliamentary Return—Differential Duties in the United Kingdom—issued by the Customs in 1904. It is a very complete and well-compiled Parliamentary Paper. It presents a very able statement relative to the Customs system of this country in former years. The impression which this return conveys is, that a system of Customs duties, such as the tariff of the middle of the nineteenth century, would be far too complex, detailed, and extensive to be suitable to the conditions of British trade at the present time. I would add, with deference to the Board of Customs and their very capable staff, that complicated tariffs need technical knowledge on the part of Customs officers. None of the present staff of Customs officers possess personal and practical knowledge of the working of a complex system of duties. While, therefore, suggestions are submitted in principle for a readjustment of Customs duties and preferential treatment in favour of colonial products, it is not expedient on present information, as matters now stand, to enter into details. Sir Charles Dilke, speaking on the 9th of October, 1904, pointed out certain difficulties in the application of differential duties in the existing circumstances of our oversea trade. These difficulties (and also those connected with certificates of origin) must be dealt with in a full and impartial inquiry. It is not intended to advocate measures which would be hurtful or irksome to trade, or which would embarrass Customs' officers.

Exception has been taken to the application of differential duties without, in each instance, previous recourse to Parliament. Executive functions cannot properly be transferred to the Legislature. The executive now possesses power of immediate action in sanitary matters. Similar power existed under the Act 8 & 9 Vict. cap. 90, in Customs matters. This Act authorised the levying by Orders in Council of retaliatory duties against countries which did not allow most favoured nation treatment to the United Kingdom. The reasons why this Act lapsed would be ascertained in the course of a duly authorised and official fiscal inquiry.

Coal and Sugar Duties.

The coal and sugar duties have been subjects of controversy, and it has been alleged that they prove the injurious effects upon trade of the imposition of such duties. The inference alleged is, that these effects are such as to be fatal objections against the policy of fiscal reform, in the sense of readjustment on the lines suggested in this paper. This objection requires to be examined. Putting aside in each case partizan views, the Final Report of the Royal Commission on Coal Supplies, paragraph 130, states that the witnesses who appeared before them "expressed strong opinions against the tax, which they believed was diminishing, and would diminish, the export of coal, and consequently injure their trading power." The Commissioners state their opinion, "Although the figures do not conclusively prove it, we cannot doubt that an export duty must restrict the tonnage exported." Let us now see what "the figures" really tell us. The latest Board of Trade returns give the following quantities of coal, coke, and patent fuel, in tons, exported from the United Kingdom in the years 1092, 1903, and 1904:—1902, 44,897,948; 1903, 46,622,7co; 1904, 48,250,280 tons. The figures "conclusively prove" a growing and not a diminishing trade. There has been a diminution in the quantity of South Wales coal exported to France. The explanation is (1) that the Cardiff trade has obtained better prices in supplying belligerent fleets, and has preferred that course; and (2) that, in the ordinary methods of business, French supplies have latterly been furnished from other quarters.

The Sugar Duty.

The case of the sugar duty in relation to the price of sugar is summed up in the following terms in the "Monthly Record" of the Manchester Chamber of Commerce for November, 1904:—

"In the produce trade the most noteworthy feature has been the great advance in the price of sugar during the past month, which has seriously affected the users of that commodity. This rise has been brought about partly by the restricted field from which British merchants now draw their supplies, owing to the terms of the Sugar Convention; partly to the shortage in the crop of Continental beet, and partly to the tax on sugar imposed to meet the exigencies of the Chancellor of the Exchequer. A movement is on foot, on the part of those interested, to obtain relief, so far as the situation can be ameliorated by legislative action."

The question of sugar bounties has been fully placed before the country from time to time in Papers presented to Parliament. Every administration during the last 40 years has been opposed to them, and, when the opportunity occurred, the endeavour has been made to put an end to them. Every administration has held that the general advantage to British interests which the suppression of these bounties will confer would outweigh the loss which might possibly at first ensue. The circumstances of the case—details are too long to be set forth in this paper—were such that the powers which allowed bounties to be obtained by sugar refiners, would only act towards their suppression by means of an international agreement. The first Convention was signed November 8th, 1864, when Mr. Gladstone was Chancellor of the Exchequer, and Mr. Milner Gibson was President of the Board of Trade. If it is admitted that the general policy of the British Government in this matter was right, it does not follow that every stipulation in each successive Sugar Convention is to be approved. It is to be remembered, however, that if the principle of the suppression of bounties is accepted, the action taken must be adopted by common consent. The foreign powers concerned would not, in the interests of their trade, agree to suppress bounties, if the markets of the countries parties to the Convention remained open to sugars from countries which continued to allow bounties. If suppression was to be effected it must be effected by common action, or not at all. The French economist and freetrader, M. Yves Guyot, an honorary member of the Cobden Club, said with reference to the Convention of March 5th, 1902: "The success of the sugar conference is the most important achievement of economic liberal policy in Europe since the signing of the Commercial Treaties of 1860" ("Journal of the Royal Statistical Society," 1902, p. 440).

Passing from the general statement to the facts of the case, the latest Board of Trade returns give the following statistics of the imports and consumption of sugar, and of the exports of confectionery and aerated waters—trades which allege specific injury from the operation of the Convention of 1902 and the sugar duty:—

Sugar.

	1902.	1903.	1904.
Imports (cwts.)	31,586,909	31,237,399	32,294,442
Home consumption	30,716,364	27,678,442	30,479,985

		Saccharin.	
Imports (oz.)			
	1,045,760	638,753	664,325
Home consumption			
	941,193	483,644	586,178
		Confectionery.	
Exports (cwts.)			
	333,763	319,736	314,780
		Aerated Waters.	
Dozen bottles			
	829,301	869,174	925,098

Approximate estimates given to me by persons acquainted with the confectionery and aerated waters trades are that the sugar used in confectionery is about ¾ refined and ¼ unrefined; and in aerated waters a mixture of refined and saccharin. There are no figures available respecting the home trade in these commodities.

As regards prices of sugars, Mr. Sauerbeck, wrote on January 15, 1904 (*Times* of the 16th):—

The average price of beet sugar in 1903 was 8s. 3d. per cwt., f.o.b., against 6s. 9d. in 1902 and 10s. in the decade 1893-1902; of Java 9s. 9d, per cwt., against 8s. 6d. and 12s. 3d.; of French loaves 11s. 9d. per cwt., f.o.b., against 10s. and 13s. 6d. respectively; at the end of the year beet sugar was worth 8s. 5d. per cwt., f.o.b., against 8s. 2d. in 1902.

And on January 13, 1905 (*Times* of the 14th):—

German beet was worth 8s. 5d. per cwt., f.o.b., at the end of 1903 and less than 8s. in January and February; it gradually rose to 11s. in September, but in consequence of the reduced beet sugar crop in Europe, now estimated to yield a reduction of more than a million tons, great speculation ensued, carrying the price to 14s. 5d. at the end of the year. Java sugar rose from 9s. 6d. per cwt. at the end of 1903 to 15s. 6d., and French loaves from 12s. 9d. per cwt., f.o.b., to 18s. 3d.

Such then are the statistics bearing upon the trades in which sugar is largely used.

Taking in order the points raised in the preceding extract from the Manchester Chamber of Commerce "Record,"—first as to the "restricted field from which British merchants now draw their supplies, owing to the terms of the Sugar Convention." It is to be observed that this restriction is limited to Russia and the Argentine Republic. Statistics for 1904 are not yet available:—

	1902.	1903.
Russia—		
Refined (cwts.) ..	nil	80,049
Unrefined (cwts.)..	6,538	23,245
Argentine Republic—		
Refined (cwts.) ..	6,000	nil
Unrefined (cwts.)..	808,951	418,386

This particular "restriction" is therefore small in relation to the total amount of sugar importation, and it cannot seriously be alleged to affect trade. Next as to the "shortage," this occurrence is to be attributed, as Mr. Sauerbeck says, to the "reduced beet sugar crop in Europe," and arises from climatic conditions. The Sugar Convention of March 5, 1902, took effect on the 1st of September, 1903. Its provisions were well known upwards of a year before it came into operation. The interval was too short to allow of a large increase of cane sugar under the security against hostile bounties which the Convention affords. The Board of Trade returns show an increase in cane imports, and to this extent the Convention has been beneficial and not injurious to the various branches of the sugar trade. To allege that the Convention had anything to do with the summer weather of 1904 and its consequences would be a "Tenderden steeple" argument. Lastly, as regards the effect on prices of the sugar tax imposed by the Budget of 1901, Mr. Sauerbeck's figures show that the lowest prices ruled in 1902. According to the Board of Trade returns, the average cost per pound in London was—1899, 1·5d.; 1900, 1·5d.; 1901, 2·0d.; 1902, 1·5d.; 1903, 2·0d.; 1904, 2·25d. These prices, the fluctuations in previous years shown by the Board of Trade chart and the information given by Mr. Sauerbeck, indicate that the recent variations in the price of sugar are to be attributed to natural causes. Sugar refining in this country is now a reviving business. Sugar cultivation, as shown in the Society's *Journal* of the 17th of February, p. 347, is being developed in tropical and sub-tropical countries; and the prices quoted for this year's beet sugar are already lowering, and indicate the expectation of an adequate European supply this year. *The Times* comment on the deputation to the Chancellor of the Exchequer on the 13th of January, 1905, is borne out by the subsequent course of trade, that seldom has a weaker case for the abolition or a tax been presented to the Treasury.*

The Question before the Country.

Certain cautions should now be adverted to:

1. Free trade is not an application of new principles first propounded in the nineteenth

* The above section was written previous to the debate in the House of Commons on the 27th and 28th of February. The only remark necessary to make on this debate is that it strengthens the argument for the need of a two-fold supply—cane as well as beet—and accordingly justifies the Convention of March 5, 1902.

century. The industrial history of England proves that public opinion and policy in fiscal matters has varied. The respective systems of Free Trade and Protection, or, as Dr. Cunningham styles them, Plenty and Power, have alternatively been adopted and changed. The last Protectionist phase was of long continuance; it began when England became a colonial and mercantile State; it was rigidly applied to navigation under the Commonwealth; and it was extended to land in the reign of George III.

2. Professor Marshall, in "Principles of Economics," vol. 1, page 90, writes: "An economic law is applicable only to a very narrow range of circumstances which happen to exist together at one particular place and time, but quickly pass away. When they are gone, the law, though still true as an abstract proposition, has no longer any practical bearing . . . . every age and every country has its own problems, and every change in social conditions is likely to require a new development of economic doctrines."

3. Professor Ashley, in the preface to "Economic History," observes that, economic theories are based consciously or unconsciously on conditions present when these theories become prevalent.

4. Other factors, therefore, besides direct economic conclusions, require to be taken into account in questions which enter into practical politics.

5. It is to be borne in mind, as was shown in the paper of December 2nd, 1903, that the repeal of the Corn Laws did not, in itself, lower the price of bread—that wheat did not fall, permanently, below 40s. per quarter until 1884, and was cheapened by other causes.

6. It is also to be borne in mind that the fiscal legislation of the forties did not lead, in itself, to an extension, either of our own foreign or of international trade. Mr. Cobden recognised this fact, and changing his course of action induced, in 1860, the Governments of Great Britain and France, to adopt the policy of tariff commercial treaties, which accomplished the object in view. According to a statement made by his personal friend, Mr. Henry Blackburn (*The Times* of March 28th, 1904), if treaties failed Mr. Cobden advised retaliation.

7. The classification of goods, and the precise rates of duties, to be proposed, are details on which the Customs would advise. The aim in view is not to increase the cost of living or of manufactures.

8. We must beware lest any expression of opinion based on economic, industrial, or scientific grounds should be, or appear to be, governed by party consideration. Without undervaluing convictions, or the truths which they affirm, the spirit of our investigation should be an earnest desire to look at facts thoroughly and sincerely—having done so—then to adopt the conclusions to which they truthfully lead.

9. The fiscal question comprises various and complex subdivisions. The last words in the controversy may not be wholly and entirely on one side in the controversy. Some details are likely to prove to be instances in which there will be five points in favour of one, and four points in favour of another solution.

Mr. Balfour stated the question which he puts before the country in these words, on the 26th of January, 1905:—

"First, I desire such an alteration of our fiscal system as will give us a freedom of action impossible while we hold ourselves bound by the maxim that no taxation should be imposed except for revenue. I desire this freedom in the main for three reasons. It will strengthen our hands in any negotiations by which we may hope to lower foreign hostile tariffs. It may enable us to protect the fiscal independence of those Colonies which desire to give us preferential treatment. It may be useful where we wish to check the importation of those foreign goods which, because they are bounty fed or tariff protected abroad, are sold below cost price here. Such importations are ultimately as injurious to the consumer as they are immediately ruinous to the producer. Secondly, I desire closer commercial union with the Colonies, and I do so because I desire closer union in all its best modes, and because this particular mode is intrinsically of great importance, and has received much Colonial support. I also think it might produce great and growing commercial advantages, both to the Colonies and the Mother Country, by promoting freer trade between them. No doubt such commercial union is beset with many difficulties. Those can best be dealt with by a Colonial conference, provided its objects are permitted to be discussed unhampered by limiting instructions. Thirdly, I recommend, therefore, that the subject shall be referred to a conference on those terms. Fourth, and last, I do not desire to raise home prices for the purpose of aiding home productions."

Mr. Chamberlain, summing up on the 1st of February his previous utterances, stated the question before the country to be first, a problem of Empire; and, secondly, a problem of employment for the people. The first task and duty is "to unite varying races, varying interests, and different aspirations," and to make

them "an organised whole." The position is only just beginning to be understood and appreciated. "It is a great potentiality, the greatest that has ever been given to man; but, for the moment, it is a loose bundle of sticks, bound together indeed by a thin tie of sentiment and sympathy, but a tie, after all, so slender that a rough blow might shatter it and dissolve it into its constituent elements." The problem of the social condition of the people—of employment—depends upon recognition of the facts of the case in relation to the present economic and industrial position of affairs in the world, and the policy in these matters of competing countries. Mr. Chamberlain has described his proposals as a sketch or outline for consideration and discussion; stated briefly, new duties of moderate amount on agricultural produce, and a 10 per cent. tax on foreign manufactures. This scheme is being worked out by the Tariff Commission, of which Sir Robert Herbert is chairman; their object is stated in a letter which Mr. Hewins, the secretary, addressed to me, forwarding papers for the Exeter Chamber of Commerce, "to obtain the exact facts of the business situation and not mere opinions for or against any fixed proposition." Until the recommendations of this body are before the public we cannot say anything as to the results of their labours; yet from their papers, relative to the iron and steel trades, it would seem that the enquiry is conducted from the standpoint of English manufactures, and may constitute a "case" from this point of view. At all events, it is very useful, in the interests of free discussion, to learn the proposals of persons, who wish for any particular changes, stated in their own words. Opinions in support of the opposite policy have been expressed by (1) Sir Henry Campbell-Bannerman, on the 17th of November, 1904: "They had, from the first, guarded against being represented as holding that free trade was, in itself, any sufficient and final security for the nation's well-being, or that they were disposed to rest satisfied with many of the conditions which prevailed in this country." (2) Mr. Herbert Gladstone said, on the 6th of December: "The conditions of modern industry were very different from what they used to be. There were now vast joint stock companies, and the sense of individual responsibility was consequently lessened. The result was that when there was a wave of slack trade, men were discharged in tens of thousands throughout the country." (3) Mr. Asquith, on the 13th of December, asked people "not to blind themselves to the real dangers which beset our trade and imperilled our national prosperity. The over-sea trade was not an exhaustive or altogether reliable criterion of the resources of the country. There were symptoms of stagnation which called for thought." These opinions were expressed in support of an alternative policy, namely, various means intended to alleviate existing burdens and conditions combined with the maintenance of the present fiscal system. This alleviation, it is urged, may be obtained by means of a reduction of national expenditure, by recourse to improved trade methods, by the adoption of better education, by new provisions relative to small agricultural holdings and forestry, and by extending employment. These alternatives have been put forward somewhat vaguely without indication of the precise enactments in view. Certain measures of this nature would be useful as far as their influences could extend. The question of reduction of expenditure has been dealt with already. It is imperatively necessary not to imperil the national safety or to endanger our colonies. The security of the British and other white populations in the West Indies and other localities far outweighs the small savings to be effected by the withdrawal of garrisons, which savings would be more than lost in insurrections or wars. Several of the suggestions mentioned are fragmentary rather than comprehensive. They do not cover the ground, and in some instances would involve increased expenditure. The controversy has been obscured by certain positive statements: (1) That food must not be taxed—whereas, in present practice, it is proved that a large revenue is derived from Customs duties on food. In principle, therefore, a proposal (for instance) to place a low duty on wheat, and to reduce the duty on tea or sugar, is in harmony and not at variance with our existing fiscal system. (2) It is alleged that if "you begin with 2s. you will follow the experience of other countries, and there will be no stay until the duty is grinding and substantial." The conditions of the population of the United Kingdom, France, Germany, the United States, and other countries (which the Board of Trade designate "protected") are widely different. Our distribution of population, as shown in the beginning of this paper, precludes a system of rigid protection. But there is nothing in economic science to prevent a re-adjustment of the details of the fiscal sys-

tem adopted in 1846 and 1860. Previous free trade systems have been varied. It is further to be remembered that Customs duties are fixed by resolutions passed by the House of Commons, which will not be passed, or at all events cannot be long acted upon against the will of the country: taxes are not altered or raised merely in consequence of having been once imposed. (3) "Retaliation never succeeds, and is injurious to the power which resorts to it." Instances are cited in the paper of December 2nd, 1903, and others might also be adduced in British experience, which prove that these two assertions are incorrect. As the same time, it is admitted that the first result of resistance to an assailant may be a harder blow—but there is a duty and necessity of self-defence. (4) Sir Edward Grey said on the 6th of January, 1904, if our customs tariff is settled by political pressure, "never again should we have the same purity about politics as we have to-day. It would become a matter of log-rolling between different trades." This warning is correct. The suggestion offered on the 2nd of December, 1903, and now repeated, is that our tariff shall be fairly short, simple, fair, and remunerative. The course of action suggested would, it is believed, prevent the evils indicated.

In conclusion—to sum up—it is hoped that the preceding pages, in addition to the previous paper of December 2nd, 1903, have explained the industrial and economic state of this country; the attitude and policy of foreign Powers; the position as regards India, and the Colonies; the proposals before the country; and the alternatives and objections to these proposals. It is hoped, too, that nothing has been said to increase partisan feeling. The endeavour has been to submit a statement which will complete the former paper and present the fiscal question in its more recent aspects. It is a subject of real importance to each person in the country individually. The Association of Chambers of Commerce adopted on the 9th of March, 1904, the following resolution:—"That the United Kingdom has just cause of complaint of certain restrictions and unfair arrangements directed against the commerce of the Empire, and that the Chambers of Commerce would support His Majesty's Government in measures of negotiation, and urge the Government to appoint a Royal Commission to investigate and report upon the whole fiscal policy of the nation."

At their meeting on the 1st of March, 1905, the Chambers dropped the recommendation in favour of a Royal Commission. By a vote of 42 to 21—39 Chambers not voting either way—direct action against unfair competition, to effect a lowering of hostile tariffs, for promoting Imperial trade, and in favour of a Colonial conference, was asked for. Lord Goschen and Lord Brassey support the proposal for the appointment of a Royal Commission. The Duke of Devonshire's secretary wrote to a correspondent that "The Duke has never objected to any enquiry into the fiscal question, but he is not sure that a Royal Commission would be the best means."

It is thus shown that there is a general admission that the present economic and fiscal system of the country is not satisfactory. Is it not the case, when firm ground in the discussion is reached, that differences on this point have been somewhat overstated? Ideas remain in men's minds, and influence their expressions of opinion, after these ideas cease to correspond with facts. While words remain the same, the technical terms and sense attached to them vary in course of time. As Dr. Jowett said, we cannot really understand "propositions if we are unable to 'reword' them. We do not know ourselves, nor can anyone else know, whether we have pierced beneath the environment of language which encloses them to the truth beneath."

This reasoning fits in with much of the use of the terms "Free Trade" and "Protection." We need to know the exact meaning now attached to words, to get at facts, and to ascertain present requirements. The course of action to which this paper leads is a free and full investigation of the fiscal question, impartially conducted, in its home and colonial aspects. The administration in office alone can give this enquiry an authorised and competent shape; they alone can properly determine its designation, constitution, nature, and scope, and supply the materials needful for the investigation. Next, as regards the tariff part of the question, the Netherlands tariff is an instance of a tariff comprising a large number of items charged with low revenue duties. The working of a tariff of this nature should be considered in its possible illustration of the working of a similar tariff in the United Kingdom; a shorter tariff would probably suit us better. Then as regards the difficulty and delay in such an investigation, when the administration of 1868 accepted the policy of the addition of compensatory duties to the rates of French import duties fixed by the Treaty of 1860, I was

appointed to act jointly with a French commissioner in adjusting these sums. The task was accomplished in six weeks, to the satisfaction alike of the Free Trade administration in London, and of the Protectionist government in Paris. This fact shows that there would be no real difficulty in considering the readjustment of our Customs duties, without endangering any interests, and without resort to extreme measures, in order to fulfil the altered circumstances of our times. The main objects would be to afford relief to home industries; to benefit our working population; to extend trade relations with the Colonies; and to counteract hostile foreign tariffs. To what result this enquiry may lead, and how far a readjustment of tariffs may be found practicable, must be, until the enquiry is well advanced, open questions. All that can properly be claimed now is that this enquiry is necessary; and that it ought to be full and free. This claim is surely not at variance with principles of progress; those who advocate enquiry and a Colonial conference are really progressives. Lastly, the fiscal question, as now placed before the country, is not likely to be dropped; nor is it likely to be settled, except by a solution which will be upheld by a large preponderance of public opinion. Our functions are restricted to considerations based on general economic grounds. We cannot properly discuss details of particular schemes, or tentative suggestions, which may not be borne out in an authorised and free enquiry. The Society of Arts has helped forward many movements of public utility. If we can now, in some measure, aid public opinion towards the settlement of questions of deep importance to our home industries and commerce, as well as to Indian and colonial interests, we shall be following our predecessors in fulfilling the objects of our Institution.

DISCUSSION.

The CHAIRMAN called attention to the fact that in order to allow good time for debate, Sir Charles Kennedy had omitted many valuable portions of his paper, but on reading it fully in the *Journal*, he was sure that all would agree that it was a masterly exposition of the facts and conditions of the fiscal system as it stood at present. The concluding paragraph of the contribution gave the keynote of the spirit which should actuate those who intended participating in the discussion. Sir Charles's desire had been to aid public opinion in arriving at a conclusion on an admittedly difficult question, and one which was fraught with vast importance to the weal or woe of our country and our Empire; and at the same time Sir Charles disclaimed any party or partisan spirit. That calm judicial spirit seemed unfortunately to have been lacking so far in the study of the subject, as presented by public men, and often in the contributions to the public journals. It was very unfortunate that the subject had been relegated to the arena of party strife, because one result had been the use of arguments which were more ingenious than honest, and an exaggerated importance was given to unimportant details. The very difficulty of the subject should be a fascination for the student to get at the bottom of it. In illustration of his contention, very little consideration had been given to the effect which a change in fiscal policy would have on the banking and shipping of the country—two most important interests. As a colonial he could assure his hearers that the colonists would not approach the subject in any selfish spirit. Many people in England thought the recent scheme originated in the Colonies, and that the Colonies were seeking to obtain the best of the bargain; but, if he knew anything of the Colonies, he could give the assurance that that was very far from the animating idea. The Colonies were prepared to make as great sacrifices as they expected the people in this country to make. The idea that Canada and Australia would expect a measure which would result in dearer food for British people was ridiculous, for it was with the working classes of England, from which the colonists mainly sprang, that their chief sympathy rested. Moreover, some of the colonies, without receiving anything in return, had already given substantial benefits to British trade, and others would fall into line as soon as the scheme was matured. It was obvious we could not seek, under the present system, to expand our home trade, because it was everybody's trade, and we could not expect to expand our foreign trade, because we were shut out of the markets, so that the only field possible for the expansion of British trade was the Colonies. True, the volume of colonial trade at present was not equal to the foreign, but the latter was a decreasing quantity while the latter was increasing.

Major CRAIGIE thanked his old friend the author for his able paper, and for enabling so many difficult subjects to be discussed on the common ground of ascertained facts and figures, which was the only sure and definite method of arriving at a conclusion on the subject. He specially referred to the diagrams exhibited, setting forth the proportions of the population engaged in various occupations, and the wider fact as to how the population of the Empire was made up. It would have been interesting if the analysis could have been extended to the Colonies and to our Indian possessions. It was of great interest to see that the occupation which bulked the largest was that of agriculture, and that

the next largest was the class engaged in domestic service. Other important Tables were those giving the taxation and imports into this country and the extraordinary changes, over a series of years, in the sources of those material imports—such as the meat and the wheat supplies, particularly the increases from Argentina and India, and from Australasia.

Dr. BENEDICT GINSBURG said all must feel grateful to Sir Charles for his able paper, which was remarkably free from party politics, and marshalled facts and figures with singular lucidity. On the question of taxation, Sir Charles had shown that one-third of the population of our country was unoccupied, which seemed to show that everything was not for the best in this country, and that our system had not helped us forward in the way one might desire, considering the extraordinary position occupied by England and her wealth of mineral industries. With regard to Imperial taxation, Lord Selborne spoke in the House of Lords the previous evening on the cost of national defence, remarking that if it were not for the strength of the British navy it would be impossible for our present fiscal system to continue. That could be put in another way. When we were getting the cheap loaf we were paying a certain amount for the loaf in cash, but we were also paying something in the taxation which went to keep up the defence of the country, and the apparent cost was not the real cost. It was strange that so many people who argued against the possible taxation of food were those who suggested we were spending too much money on the necessary defence of the country. Money had also to be found for local taxation, which was growing rapidly. The burdens which had to come out of an industry in any way were a tax upon the industry whatever they were called, and to whatever they were applied. The manufacturer who had to pay a certain sum of money in rates had his business as much burdened as if he were paying an equal sum on the raw material which he worked up. It was considered unfair that he should pay on the raw material, but it was not considered unfair that he should be burdened with rates to provide baths and wash-houses for people whom he did not want to see washed.

Mr. ARMYTAGE BAKEWELL recalled Lord Salisbury's remark that our great difficulty with regard to the tariffs of other countries was that we had nothing to give in exchange; we had no power of retaliation; we could not say, "If you take off your duties on such and such goods we will allow your goods to come in on easier terms." A former leader of the Anti-Corn Law League had told him he was firmly convinced that a change of policy was now necessary. We never had free trade, for we taxed things we did not produce, and did not tax things which we could produce. The result was we were preventing our people having the home market they ought to have. It was strange that a statistician did not point out, in dealing with the preponderance of agriculturists and domestic servants, that one was a productive and the other a non-productive class. Mr. Cobden himself repeatedly emphasised the fact, and he advocated free trade on the assumption that other nations, seeing its immense benefit, would soon fall into line. But those people had been wiser than we had. The question had been put before the audience in the ablest possible manner that evening because it had been dealt with entirely outside party. We were helping to pay Germany's taxes, and we required a system whereby Germany should help to pay ours. It was a great pity the question was put on one side in the House of Commons by those who seemed afraid to call their souls their own. Our leaders must lead the people, and not simply ask them what they wanted.

Mr. W. BOUSFIELD wished to refer to the statemen by the author that this had become, to a large extent, a residential country: that those who resided in it and were not classed under any special head formed a very large part of the population. There were many advantages in that, and indeed it was necessary for the central city of a widespread Empire. Free trade had made England one of the best places to reside in in the world, and one did not now find large numbers of English people residing abroad for the sake of cheapness of living. The same cheapness largely affected the working classes, who had to carry with them a large number of ineffectives——widows, young children, those who were aged. The working classes had shown a perfectly sound instinct in the matter; they had seen that to put taxes upon food and upon various manufactures must increase the expenses of their daily life. What was called the unoccupied class, was the product of the wealth of the country during centuries, but it had rapidly increased in the last forty years, and it was difficult to believe that the fiscal policy during that time had had much to do with it.

Mr. G. BYNG, speaking as a producer, who was born abroad, but had lived in this country 25 years, referred to "dumping," which had been defined as selling goods in a country under the market value. But he thought dumping could not be defined, and that an erroneous impression about dumping was at the root of the differences existing between those who advocated protection and those who held to free trade. It was agreed that dumping killed industries and killed the producer. But the free-trader said that for that disadvantage we got cheapness. He spoke from experience when he said that foreigners were not sending their goods into our country for nothing, even under cost price; but they were paying

dearly for it. The advantage of free trade and of cheapness were non-existent, and the idea that the English working classes lived cheaper than those on the Continent was wrong.

Mr. G. G. CHISHOLM, while thanking the author heartily for his able paper, said it must be conceded that the subject was very difficult and complex. Geographical circumstances might be of great importance in the arguments raised on the question, and he instanced the case quoted in the paper regarding the farmers in Minnesota. He admitted that the Minnesota and Dakota farmers would have to accept a smaller price than the farmers of Manitoba, but it did not follow that the prices in the North-West Territories would not be higher than they otherwise would be in consequence of the duty. In Canada there was a natural tendency to the expansion of wheat fields, and that had been accompanied by a very great migration from the United States into Canada. Granting a preference to Canada would go far to stimulate a transference of the population from the wheat-growing areas of the United States to Canada. But the United States had rapidly become much more of a manufacturing country, so that the amount of wheat it could spare for export had been recently a diminishing quantity, and there had been a tendency for immigration into the United States to be a steady stream. In conclusion, he referred to the great variation of the sources of supply of wheat, from Argentina, India, and Australia, and pointed out the importance of depending on a world-wide supply, and not doing anything to restrict our source of supply to one or two parts of the world.

Mr. NATHANIEL COHEN supported the general tenour of the plea in the admirable paper of Sir Charles Kennedy, because it agreed with the proposal which he supported at the Congress at Montreal nearly 18 months ago on behalf of the Chambers of Commerce and which was carried unanimously. But he did not agree with the plea for further discussion in the present House of Commons, for the continual recital of opinions from familiar speakers in that assembly did not seem to forward the question at all, and there seemed a tendency to avoid points which were the very crux of the matter. Mr. Bousfield had mentioned the great importance of not raising the cost of living, with the view to retaining the residential amenities of this island, but that gentleman ignored the very keynote of those who came forward to urge the greater development of our Colonies, viz., that under the existing conditions we were within measurable distance of finding the cost of food rising from natural causes. Fully 90 per cent. of the most fertile lands of Canada had not yet been brought under cultivation. People seemed absolutely indifferent to the notable fiscal advantages which had been granted to us by our nearest colonies, and at Montreal it was mentioned that since that rebate the cash value accorded to British trade and manufactures amounted already to £2,600,000, and by now the figure would probably be £3,500,000. It was unsatisfactory that we should receive that contribution and not be willing to enquire fully whether, without substantially raising the cost of living, we could not reciprocate in some way acceptable to the Colonies. Discussion had been pleaded for on the basis of facts and figures, but he also asked that human experience should be regarded; it was not sufficient to ask abjectly for something; we should be able to urge the requirements by something tangible. The subject having been allowed to drift on to party lines, with the consequent acerbation of the discussions on it, it was difficult to find men free from partisan political affinities.

A hearty vote of thanks was accorded to the author, on the motion of the CHAIRMAN.

Sir CHARLES KENNEDY, in reply, thanked his audience, and more particularly the speakers, for the kind reception given to his paper. The points which had been made by the speakers would add much to the value of the record in the *Journal*. He had dealt slightly with the question of local taxation, but full information is contained in the writings of Sir Robert Giffen quoted in the paper. A section on employment had been sketched in the first instance, but, in view of the able analysis of the last Board of Trade Blue-book, to be found in the Society's *Journal* of the 24th of February last, it seemed unnecessary to compile another version of the subject.

THE REGISTRAR-GENERAL'S ANNUAL REPORT.

The Report of the Registrar-General of Births, Deaths, and Marriages in England and Wales, issued recently, shows that the fall in the birth-rate has not been checked. The method of measuring the birth-rate by calculating the proportion of births per 1,000 women of conceptive age (15-45 years), as an alternative to calculating the proportion of the total population, is for the first time adopted in this report. It is believed by the Registrar-General to be a preferable method by which to measure the birth-rate. Unfortunately, it discloses even a greater fall than has hitherto been shown. The proportion of total births per 1,000 women, aged 15-45 years, taking three-year periods, is as below:—

1870-2.	1880-2.	1890-2.	1900-2.	1903.
153·7.	147·7.	129·7.	114·8.	113·8.

The proportion of legitimate births per 1,000 married women, aged 15-45 years, fell from 292·5 in 1870-2,

to 233·3 in 1903, and of illegitimates in the same period from 17·0 to 8·4. The deaths registered in England and Wales during 1903 were in the proportion of 15·4 per 1,000 persons, being the lowest rate hitherto attained, the next lowest being 16·2 in 1902.

The decrease in the marriage rate continues. The subjoined Table shows the annual marriage rates of both bachelors and widowers, and both spinsters and widows, calculated on those sections of the population aged 15 years and upwards :—

	Bachelors.	Widowers.	Spinsters.	Widows.
1880–82	55·7	58·2	56·9	18·2
1890–92	54·8	53·4	54·5	16·3
1900–02	54·7	44·4	53·0	14·4
1903	54·0	40·6	52·2	13·4

It will be seen that the decrease in the marriage rate is general, but it is considerably greater among widowers and widows than among the unmarried of either sex.

It is good to observe the steady fall in the mortality of pulmonary tubercolosis. It continued throughout the period covered by the present report, the loss of life from this dread disease being now only three-fourths of what it was twenty-five years ago. Unfortunately similar comfort is not to be derived from the cancer statistics. The deaths referred to cancer, or malignant disease, amounted to 29,089, exceeding by 2,795 the average number in the previous ten years corrected for increase of population. Among males the corrected numbers were in excess by 15 per cent., and among females by 7 per cent. If the deaths from malignant disease be calculated on the aggregate population the disease appears to have exacted a death total at all ages of 732 per million among males and of 1,003 per million among females. Both these rates are the highest on record. The following figures give the rates of mortality from cancer per million living at each of five groups above the 35th year, the "average" being the average rates in the five years immediately preceding 1903:—

	Average.	1903.
35	·650	·671
45	1·920	2·039
55	3·987	4·164
65	6·287	6·626
75 and upwards	7·077	7·571

Compared with the average in the previous five years the increase of cancer mortality in 1903 was greatest at the higher ages. Other figures show that in both sexes the increase appears to have been greatest in the urban counties.

In 1853, 304 out of every 1,000 men, and 439 out of every 1,000 women who married signed the marriage register by mark. In 1903, only 19 out of 1,000 bridegrooms and 23 out of 1,000 brides failed to sign their names. In the year under notice, of the total number of illiterates 55 per cent. were women and 45 per cent. men. In London, which is exceptional, the number of husbands who signed the marriage register by mark averaged 22, and the number of wives averaged 31 per 1,000 marriages. But illiteracy is practically confined to a group of five registration districts—London City, Bethnal-green, Whitechapel, St. George-in-the-East, and Mile-end Old Town. Excluding these districts the proportions of illiteracy in London will be reduced to nine signatures by mark of husbands and 12 of wives in every 1,000 marriages. In the following Table, the five districts are compared with the remainder of London — :

Registration district.	Signature by mark, per 1,000 marriages, 1903.		Jewish marriage per 1,000 marriages 1903.	Natives of Russia, Helgium, Poland, Servia, Roumania and Bulgaria per 1,000 of the population in 1901.
	Husbands	Wives		
London City	89	85	359	13·3
Bethnal-green	37	63	—	27·3
Whitechapel	164	240	461	265·1
St. George-in-the-East	37	123	115	241·0
Mile-end Old Town	251	241	482	89·4
The above five districts	150	210	320	117·4
The remainder of London	9	12	4	2·2

Nearly all the signatures by mark in London City, and in Mile-end Old Town, occurred in marriages of foreign Jews. The apparent discrepancy between the large proportion of Jewish marriages in Mile-end Old Town, and the comparatively small population of foreigners resident in the district, is due to the fact that many of the marriages are those of Jews resident in St. George-in-the-East, Whitechapel, Bethnal-green, and other districts.

CORRESPONDENCE.

METHODS OF DESIGN EMPLOYED IN MOHAMMEDAN ART.

In the brief interval between the reading of Mr. Hankin's paper on Wednesday last and the report of it in our *Journal* of this evening [the 17th March] I forgot to add many of my remarks on his brilliant paper to the "proof" received by me; and I would like to make good some of these omissions in the present memorandum. In expressing my personal opinion that Mr. Hankin pushed his ingenious theory too far, I stated that, while in India, I had employed all classes of craftsmen, under my own eyes, and that on whatever work I employed them, they never used any kind of design whatever. The "designs" in jeweller's books were mere advertisements for the attraction of Europeans, were never worked from. It was fatal to success to tell Indian craftsmen to work from a previous master-

piece of their own, if you told them to reproduce it exactly; for in duplicating it with mechanical exactitude they destroyed all its artistry,—the beauty, and the life the artist's thought and sleight had given to it. The only way to possess yourself of your desire was to say:—"May God help you to devise another thing of beauty ["sparkling," "dancing," or "prancing" thing] like this you did for me before, of the same weight and size, and equally alive and exquisite ["sparkling" &c. over again], and equally to my delight and your honour: *and you know I shall not haggle over the price.*" Then you get all you desire, *and better.* It was always in that way I consulted and dealt with these craftsmen. I would never accept trash, and, without any bargaining, I always paid in cash; and for myself and friends I always secured the best "Sidonia wares" of my day in Bombay. Never haggle about prices and you will always get the best value for money in India, as well as everywhere else in the world. The ivory and wood carvers would execute the most intricate "Arabesque" designs in wood and ivory, not only without a trace of geometrical, or even mechanical planning, but seated on the floor, crumpled up on their haunches, and using their knees as the only support of the strip of ivory or wood they held with the left hand, and worked with the right. They would work on like that all day, with no more thought of the geometry, or the anatomy of ornament, than have the bees in moulding their wonderful hexagonal cells by the rotation of their little heads. All the time I was in India I never saw a "template" or a stencil of any kind used; and I said at Mr. Hankin's lecture that I was sure he had not; and he at once acknowledged that he had not. I was observant also of a great deal of house building in Bombay, nearly all of European design and under European superintendence. The only exception was a little mosque in the north-east quarter of the Island, near the sea shore, under Chinchpoogly Hill. It was built by a small body of stonemasons; and from first to last not only without a draughted plan, but without measurements. I have often cited the case in opposition to my distinguished friend Sir Caspar Purdon-Clarke's contention that no one could build a house without a plan. I was *officiously* with these masons daily; and only occasionally would they have an aside consultation over some hitch in the construction, or some point of decoration,—which was nearly all in the proportion of the construction,—and then they would trace out their casual "plannings" in the dust on the ground, and with their forefingers, or I would help them with my walking-stick. I do not know how it is done—by instinct, by rote, or by divine inspiration (*i.e.*, genius). I only know that the thought of "Glory to God" works wonders by the hands of these men, Hindus and Muslims, and that honest payment, as God's blessing on their work, fills them with devout gratitude, and enthusiastic gratification in it.

GEORGE BIRDWOOD.

GENERAL NOTES.

BASUTOLAND.—The Basutoland census shows a rather startling increase in numbers. Comparing 1891 with 1904, the population has increased from 218,324 to 347,731, or close upon 60 per cent., the increase in females being over 64 per cent. Notwithstanding the efforts made by the Chief Lerothodi to collect the money necessary for an industrial school —he has collected £4,564, and a director has been appointed, plans drawn up, and the buildings commenced—the daily average number of scholars in the schools is only 10,401. The Resident Commissioner, in his report just published (Cd. 2238), says that the increasing desire for some form of education exhibited by a section of the people is by no means universally felt. The bulk of the young people are growing up without education as it is understood in Europe. "But it would be an error," says Mr. Sloley, "to describe as ignorance the condition of the natives who do not pass through the schools, who, as a rule, are capable of displaying an acute intelligence, and a thoughtfulness which have nothing in common with scholastic training, but are acquired by the primitive methods of keen observation, and a perpetual intercourse of man with man."

ARTISTS AND STUDENTS IN ITALY.—Mr. Consul-General Neville-Rolfe is anxious to make it generally known that the new regulations for the admission of artists and students gratis to the Italian galleries and excavations are much more stringent than they have been hitherto. In the case of artists and students they should now submit their credentials to the Italian ambassador in London, and on his certificate a pass will be granted. Until lately the certificate of the Artists' Consul was accepted. Now, unless the artist has provided himself with a certificate from the Italian Ambassador in his native country he must make his application to the ambassador accredited to the Court of Rome, who must first judge whether the applicant belongs to a "recognised academy," and if in his judgment he does so, forward his application to the Minister of Education, who eventually sends a pass to the Embassy where it is usually forwarded to the Consulate of the city from which the application is made, and then by the Consul transmitted to the applicant. The pass when obtained permits the bearer to measure, sketch, and photograph, and to go in and out of the gallery or excavation free as often as he pleases. If he wishes to copy a picture he must apply to the Director of the Gallery in which it is exhibited, who will inform him under what conditions he may work. Amateurs can obtain admission to photograph on application to the Director of the gallery or excavation in question. The application must be on stamped paper of 60 c., which can be procured of any tobacconist in Italy.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock :—

MARCH 29.—"British Woodlands." By the RIGHT HON. SIR HERBERT MAXWELL, Bart., M.P. R. C. MUNRO-FERGUSON, M.P., will preside

APRIL 5.—"Ancient Architecture of the Great Zimbabwe." By RICHARD A. HALL.

APRIL 12.—"The Industrial Resources of the State of Matto Grosso, Brazil." By GEORGE TORRANCE MILNE, F.R.G.S.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock :—

APRIL 6.—"The Prospects of the Shan States." By SIR J. GEORGE SCOTT, K.C.I.E. ("Shway Yoe"), Superintendent and Political Officer, Southern Shan States. THE MOST HON. THE MARQUIS OF BATH, will preside.

COLONIAL SECTION.

Tuesday afternoons at 4.30 o'clock :—

MARCH 28.—"The Manufactures of Greater Britain.—II. Australasia." By the HON. WALTER HARTWELL JAMES, K.C., Agent-General for and late Premier of Western Australia. HON. SIR JOHN ALEXANDER COCKBURN, K.C.M.G., will preside.

MAY 23.—"The Cape to Cairo Railway." By SIR CHARLES H. T. METCALFE, Bart., M.Inst.C.E.

APPLIED ART SECTION.

Tuesdays, at 4.30 or 8 o'clock :—

APRIL 11, 4.30 p.m.—"The Monumental Treatment of Bronze." By J. STARKIE GARDNER. SIR GEORGE BIRDWOOD, K.C.I.E., C.S.I., will preside.

MAY 16, 4.30 p.m.—"Popular Jewelry." By MONSIEUR RENE LALIQUE (Paris). ARTHUR LASENBY LIBERTY, J.P., will preside.

CANTOR LECTURES.

Monday evenings, at 8 o'clock :—

HERBERT LAWS WEBB, "Telephony." Four Lectures.

LECTURE III. — MARCH 27. — *Telephone Exchanges.*—Requirements of a telephone exchange—Early types of switchboard—Evolution of multiple switchboard—Switchboard signals—Automatic signals—Various types of exchanges—Various methods of operating—Common battery exchanges—Distribution of wires—Power plant—Telephone buildings—Automatic exchanges—Conduct of telephone traffic.

LECTURE IV. — APRIL 3. — *Development and Tariffs.*—Supremacy of telephonic communication—Essential features of modern telephone service—Organisation of telephone plant and business—Evolution of telephone rates—Scientific telephone tariff—Effect of area on cost—Varying demands of consumers—Graded classes of service—Telephone development in different countries—Long distance service and rates.

ALAN S. COLE, C.B., "Some Aspects of Ancient and Modern Embroidery." Two Lectures. May 1, 8.

HENRY WILLOCK RAVENSHAW, Assoc. M.Inst.C.E., Mem.Fed.Inst.Min.Eng., "The Uses of Electricity in Mines." Two Lectures. May 15, 22.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 27...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. Herbert Laws Webb, "Telephony." (Lecture III.)

Surveyors, 12, Great George-street, S.W., 8 p.m. Mr. F. Oliver Lyons, "The Rating of Railways—their Over-Taxation; its Causes and its Remedies."

Geographical, University of London, Burlington-gardens, W., 8½ p.m.

Actuaries, Staples-inn Hall, Holborn, 5 p.m.

Camera Club, Charing-cross-road, W.C., 8½ p.m.

Medical, 11, Chandos-street, W., 8½ p.m.

TUESDAY, MARCH 28...SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Colonial Section.) Hon. Walter Hartwell James, "The Manufactures of Greater Britain.—II. Australasia."

Royal Institution, Albemarle-street, W., 5 p.m. Prof. W. E. Dalby, "Vibration Problems in Engineering" (Lecture II.)

Medical and Chirurgical, 20, Hanover-square, W., 8½ p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. C. S. R. Palmer, "Coolgardie Water Supply."

United Service Institution, Whitehall, S.W., 3 p.m. Major the Hon. T. F. Fremantle, "Modern Military Rifles."

Colonial Inst., Whitehall Rooms, Whitehall-place, S.W., 4½ p.m. Mr. C. K. Cooke, "Emigration of State Children."

Horticultural, Vincent-square, Westminster, S.W., 3 p.m. Mr. Frank Pink, "Bananas."

WEDNESDAY, MARCH 29...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Right Hon. Sir Herbert Maxwell, "British Woodlands."

Chemical, Burlington-house, W., 4½ p.m. Annual Meeting.

East India Association, Caxton Hall, Westminster, S.W., 4 p.m. Mr. D. Edwards-Radclyffe, "Ramie, the Textile of the Future: a Promising Industry for India."

THURSDAY, MARCH 30...Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Royal Institution, Albemarle-street, W., 5 p.m. Mr. T. G. Jackson, "The Reasonableness of Architecture."

Camera Club, Charing-cross-road, W.C., 8½ p.m.

FRIDAY, MARCH 31...Royal Institution, Albemarle-street, W., 9 p.m., Prof. Joseph Wright, "The Scientific Study of Dialects."

Art Workers' Guild, Clifford's-inn Hall, Fleet-street, E.C., 8 p.m. Paper on "Furniture in Relation to Architecture."

Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m. Prof. David S. Capper, "First Report to the Steam-engine Research Committee."

SATURDAY, APRIL 1...Royal Institution, Albemarle-street, W., 3 p.m. Lord Rayleigh, "Some Controverted Questions of Optics." (Lecture I.)

Journal of the Society of Arts.

No. 2,732. VOL. LIII.

FRIDAY, MARCH 31, 1905.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

NOTICES.

NEXT WEEK.

MONDAY, APRIL 3, 8 p.m. (Cantor Lecture.) HERBERT LAWS WEBB, "Telephony," Lecture IV.

WEDNESDAY, APRIL 5, 8 p.m. (Ordinary Meeting.) RICHARD N. HALL, "The Ancient Architecture of the Great Zimbabwe."

THURSDAY, APRIL 6, 4.50 p.m. (Indian Section.) SIR GEORGE SCOTT, K.C.I.E. (Shway Yoe). "The Prospects of the Shan States."

Further details of the Society's meetings will be found at the end of this number.

CANTOR LECTURES.

On Monday evening, 27th inst., Mr. H. L. WEBB delivered the third lecture of his Course on "Telephony."

The lectures will be published in the *Journal* during the summer recess.

COLONIAL SECTION.

Tuesday afternoon, March 28th; The HON. SIR JOHN ALEXANDER COCKBURN, K.C.M.G., in the Chair.

The paper read was "The Manufactures of Greater Britain. II.—Australasia." By the HON. WALTER HARTWELL JAMES, K.C., Agent-General for Western Australia.

The paper and report of the discussion will be published in a future number of the *Journal.*

COVERS FOR JOURNAL.

For the convenience of members wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1s. 6d. each, on application to the Secretary.

THE SOCIETY OF ARTS AND THE LONDON INSTITUTION.

The Council think that the members of the Society may desire to have some information about the proposal which has lately been made for an amalgamation of the London Institution with the Society of Arts, and they therefore think it well to submit to the members generally the following short report on the question as it now stands.

In the latter part of last year an informal suggestion was made by Mr. W. T. Shaw, a member of the Society, and one of the proprietors of the London Institution, that the Institution and the Society should in some way or another unite their forces and combine into a single body. After a certain amount of private discussion, the proposal was submitted to the Board of Managers of the London Institution and to the Council of the Society of Arts, and it so far commended itself that both bodies agreed to the appointment of a committee composed of representatives of the two bodies for its further consideration. Such a committee was accordingly appointed in November, the representatives of the Society being—The Right Hon. the Lord Chief Justice, G.C.M.G., Sir William H. Preece, K.C.B., Sir Owen Roberts, M.A., D.C.L., F.S.A., Sir John Wolfe-Barry, K.C.B., F.R.S., and Sir Henry Trueman Wood (secretary); and those of the London Institution—William Henry Smith Aubrey, LL.D., Frederick Hovenden (honorary secretary), Cecil Frederick Joseph Jennings, C.C., William Thomas Shaw, Major John Amory Travers, and Robert W. Frazer, LL.B. (secretary). This Committee has held three meetings, at all of which the Lord Chief Justice presided, and eventually they submitted an identical Report* to the governing bodies of the two Institutions. This Report recommended an amalgamation of the two Corporations, and indicated the

* A copy of this Report will be sent to any member who likes to apply to the Secretary.

lines on which such an amalgamation might be carried out.

The Report was approved by the Board of Managers of the London Institution on February 9th, and by the Council of the Society of Arts on February 13th; after which the proposal was submitted to H.R.H. the Prince of Wales, the President of the Society, and received His Royal Highness's approval. In each case it was decided that the matter should be submitted for decision to a General Meeting of each body. The Annual General Meeting of the London Institution will be held on the 28th of April next, but the Council understand that the proposal will be considered, and a decision taken, at a special meeting to be summoned for the purpose on the 12th of the month. The Annual General Meeting of the Society of Arts will not be held until the 28th of June, and the question can either be submitted to the members of the Society on that day, or, supposing that the proposal is approved by the Proprietors of the London Institution, at a special meeting which the Council are quite prepared to summon, if necessary, at an earlier date.

The opinion of counsel has been taken as to the best means of carrying out a combination such as has been suggested, and the Committee has been advised that the most convenient and probably the least costly method would be to obtain an Act of Parliament. The Proprietors of the London Institution will therefore be asked to authorise their Board of Managers to promote an Act, and, if they agree, a similar proposal will be submitted to the general meeting of the members of the Society of Arts.

The Council, however, do not think that they should wait until a general meeting can be summoned before they inform the members as to the reasons which have induced them to regard favourably a proposal of so important a nature, and one which will have such great influence on the future of the Society. It is no small matter to break with the traditions of a century and a-half, and to make a new departure at a time when nothing seems to call for sweeping change. As the members can well understand, it was not without very careful consideration and some hesitation that the Council accepted a proposal involving such novel conditions. For the Society is now in a very prosperous condition. Its members are as numerous as they have ever been since the foundation of the Society 150 years ago. Its finances are sound, for though it possesses no endowment, and its margin of income over expenditure is not large, it has been able in the course of the past twenty years to accumulate out of its income a reserve fund of more than £20,000. This has been effected in despite of the fact that the Council have always felt that it was the duty of the governing body of the Society to expend on the members the income which the members provided, and not to attempt to build up a large accumulation out of current revenue. They have no reason whatever to anticipate any falling off either in the number of members, or in the revenue of the Society, or to expect that the Society will be less prosperous in the immediate future than it has been in the immediate past. It is certain therefore that they have no cause for recommending to the members any change which would involve any considerable alteration in the work of the Society, or any cessation of the various lines of work to which it has devoted itself.

There was, however, one particular point which appealed very strongly to the Council. As the members are aware, the Society's present premises, which were built for the Society in the year 1775 by the brothers Adam, are not its own freehold. The original lease, granted for 99 years, expired in 1867. It was renewed that year for a period of 30 years, and this period came to an end in 1897, when the lease was further renewed for a period of seven years, ending in 1904. The Society's landlord, Mr. George J. Drummond, felt himself unable, without injury to the other portions of his estate in the Adelphi, to lease a portion of it for a lengthened period; and at the present time the Society are practically tenants-at-will, with an option of the tenancy being terminated at two years' notice on either side. The Council think it right to say that they fully appreciate the motives which have actuated Mr. Drummond in the matter, and they feel that the Society is indebted to him for the very liberal and friendly way in which they have always been treated; but, at the same time, the situation cannot be regarded as a satisfactory one, either for landlord or tenant, and the Council therefore would welcome any proposal which would ensure the Society in the possession of suitable premises, either on the present site, or in some other suitable position. It must, however, be remembered that the present building is quite inadequate for the growing needs of the Society. The meeting-room is sufficient for

all except exceptionally large meetings, and there is no complaint to be made about its convenience. As much cannot be said for the Society's offices, which are quite insufficient for its present work. There is also very poor accommodation for the library, in fact the accommodation is so lacking that it has been quite hopeless to attempt to keep the library up to date in the way in which it ought to be kept. Nor is the accommodation for the members themselves by any means such as they have a reasonable right to expect. There is really no convenient room for the members' use, and, as a consequence, the premises of the Society are not nearly as useful to the members as they ought to be.

The London Institution, though a good many years younger than the Society of Arts, has yet a most distinguished record. For many years after its establishment, in 1807, its laboratories afforded valuable means for chemical and physical research, while it has always provided for the public lectures on subjects of Science, Literature, and Art, delivered by the most distinguished men and attended by large audiences. It is merely its position in the heart of the City, in a locality which the permanent residents have now for some years deserted, that has militated against the continuance of its useful and prosperous career. The site of its buildings in the very heart of the City, is, of course, for business purposes, of very great and increasing value, and it is probable that, whatever might be the future of the Institution, its proprietors would find it desirable to leave the building in Finsbury-circus, realise its value, and establish themselves elsewhere. But if they were to move into the western district of London, they would find themselves in the midst of other societies, established for similar purposes, and doing the same work. It is presumably this consideration which has led them to suggest an amalgamation with another similar body, rather than to add one more to the numerous scientific institutions now established in the western part of the metropolis.

The Council have no doubt that the union of two Institutions, both in a prosperous condition, and having behind them a long record of useful labour, would, if properly carried out, produce an Institution of very great influence, and capable of carrying out public objects of the very greatest value. At the same time they would hesitate to recommend the amalgamation to the approval of the members if they felt there was any probability of the various departments of the Society's present work being abandoned, or even minimised in value. They would hope that the new Institution, if established, would carry on the meetings at which so many of the applications of Science to practical purposes have been introduced, or described, to the public; that the Cantor Lectures, which now form an encyclopædic record of the progress of Applied Science for the past half century, would still be continued; that the *Journal*, though it would probably be enlarged both in size and scope, would lose none of the useful features which have distingushed it since its establishment in 1852; that the Society's examinations, which have assumed during the past few years such an unexampled development, would be continued; and that no change would be made in the work of the Indian and Colonial Sections. But on the other hand the Proprietors of the London Institution would naturally expect that the work to which their Corporation has devoted itself, would in like manner lose none of its importance, and that the scope of the new Institution should be extended so as to include lectures on matters connected with Pure Science, Art and Literature, which have not hitherto been considered to come within the scope of the more practical Society of Arts. The magnificent library of the London Institution, containing over 100,000 volumes (besides the circulating library of 37,000) would be supplemented by the library of the Society of Arts, and its value still further increased. It may also be hoped that the resources of the new Institution would permit of the promotion of scientific research, once a main object of the London Institution, but of late years perforce abandoned by it.

Special stress must be laid on the consideration that the union, if effected, would be an amalgamation of two powerful Institutions, and not an absorption of one by the other. The objects of the two Institutions are of so similar a nature, and their membership is of so closely allied a character, that there is little fear of any difficulty on this score, or any reason to apprehend that the objects which specially appeal to the members of either Institution would be neglected in consequence of the overpowering influence of the other.

As to the place where the new Institution might establish itself, nothing as yet can well be said. Associated as the Society has always been with its historical premises in the Adelphi, it would naturally be a wrench to a majority of its members if that association were broken;

and it is possible that if after full consideration the proposal commended itself to the representatives of both Institutions alike, arrangements might be made for obtaining a sufficiently large area on the Adelphi estate. If, on the other hand, it was found necessary to move, there can be but little doubt that a suitable site ought, without much difficulty, to be found in some other convenient locality.

Looking at the matter as a whole, the Council think that the new departure, startling as it may seem to many of the members, is one which ought to recommend itself to their approval, and they trust that it may be found to offer as many advantages to the proprietors of the London Institution as to the members of the Society of Arts. How and in what directions the new Institution could most usefully develop only the future can tell. That must depend on the wisdom and the care of those who may be called upon to direct its course. At all events, a confident anticipation may be expressed that among the governing bodies of the two Institutions material may be found for the formation of a new governing body, able and willing to devote itself to the promotion of the various objects for which the two corporations were founded, in the same way as the managers of the London Institution and the Council of the Society of Arts have devoted themselves to the promotion of similar objects in the past.

PROCEEDINGS OF THE SOCIETY.

APPLIED ART SECTION.

Tuesday, March 21st; G. F. BODLEY, R.A., in the chair.

The paper read was—

WEST COUNTRY SCREENS AND ROOD-LOFTS.

BY F. BLIGH BOND, F.R.I.B.A.

In introducing the subject of West Country Screens and Rood-lofts, a few preliminary remarks upon screen work in its more general aspect may not be out of place.

The chancel screen is a feature common to Christian churches of all lands and times; but whereas in some countries it is exceptional in its occurrence, in Britain it is very frequently met with, and would appear to have been well-nigh universal in former days—forming one of the most essential features of the English parish church.

In spite of the ravages of time, fire, iconoclastic zeal, and last—but not least in its destructiveness—nineteenth century "improvements" and "restorations," it is estimated that there yet remain some two thousand screens or parts of screens in our churches, and of these the West Country furnishes a large proportion, Devonshire alone contributing nearly two hundred (some of course mere fragments) and Somerset about half that number. This abundance of screen-work seems to be traceable to the strength of Oriental influence in the early British church, which laid the foundation of many peculiarities of plan and arrangement that differentiate our churches from their continental neighbours.

The earliest church builders appear to have been largely influenced by Hebrew tradition, and to have based their plans upon that of the Jewish Temple, with its tripartite divisions, separated by veils, and we find the use of veils, and of screens as a substitute for veils, perpetuated not only in the Eastern churches of later times, but in the early and mediæval churches in these islands. Early records testify to the fact that in the Celtic church a solid screen or barrier was built between nave and chancel.

The churches of those days were not stone built, but were of wood, or wattle, and it would appear likely that wicker-work was largely used in the construction of the lighter parts, as, for example, partitions and screen-work. The many remains of Celtic ornament or decorative detail as applied to stone, seem to suggest this, as they exhibit representations of twisted or plaited work, interlaced twigs and tendrils, &c., and in some cases these are elaborated into patterns very similar to those we find in the West Country wood detail of a far later date. The sculpture on the tomb of Cormac (Rock of Cashel) furnishes a good illustration of the earlier form of ornament, and illustrations of its later counterpart are here given, in the detail from the screen now at Whitchurch, South Devon, and that of Newtown, Montgomery (Figs. 1 and 2).

The west and south-west of Britain were the stronghold of the Celtic race, after the Saxon invasion, and in these districts the older Church and its traditions were never so completely uprooted as in other parts — consequently we may expect to find that local types of church building and of decorative detail would

exhibit their characteristics. In addition to this, the native stone of the West—in Wales, Cornwall, and Devon—was chiefly of a rough and intractable nature, incapable of being wrought into fine forms by the mason or carver —hence in these districts the mason's art was not brought to so great a pitch of excellence as it was elsewhere, and it naturally follows that more attention was lavished upon the wood-work.

We may thus discern two reasons for the peculiar abundance and excellence of the West Country wood-work, of which the mediæval screens and rood-lofts furnish the choicest examples, these having been from the first objects of especial regard and veneration, towards the beautifying of which every effort was made.

Parallel instances may be found in Brittany, where there exist a number of fine screens having features in common with the West British, the same conditions as race and soil here holding good.

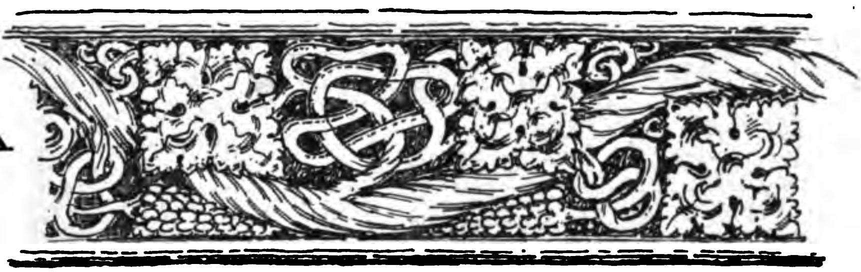
Saxon and Norman building traditions are chiefly concerned with the mason's art, and there appears little in the character of the decorative detail they employed to suggest a derivation from wicker-work or tendril forms; but in spite of the powerful influence of the style introduced by the Romanesque builders, the oldest British forms and ideas seem to have held their ground, and gradually leavened the whole of our national church architecture, giving a peculiar type of plan in which the high chancel screen is universal, screen-work of wood or stone being found in every part of England, but nowhere more abundantly than in the western districts.

There was a type of stone-built church common in Britain in early days, in which a solid barrier of masonry was built between nave and chancel. This was pierced by a single opening, not much wider than an ordinary doorway. In this we seem to discern the prototype of those heavy stone screens which are occasionally found in our country churches. Stone screens, are, however, of unusual occurrence in the West of England, though they are found in certain localities, as North Wilts, and South Somerset. Some of these are of early date, and were originally double screens supporting a gallery over, thus forming the earlier type of rood-loft as associated with the parish church.

One perfect specimen of this order remains at Compton Bassett, Wilts. The eastern

Fig. 1.

A



Detail from Whitchurch, South Devon.

Fig. 2.

B

Detail from Newtown, Montgomery.

member, forming the screen proper, consists of a wall, with central doorway, and traceried sidelights, below which altars formerly stood. To the westward is an open screen of three arches, highly enriched with sculpture and ornamental mouldings. A parallel instance is found at Le Folgöet, Brittany, which shows the altars, missing at Compton, but here in their ancient and customary position.

Of this arrangement of altars we have an instance at Patricio, in Monmouthshire, but here the screen itself is of wood, and is only a single screen. But the type of church most common in the West had no stone-built chancel wall such as that other early type I mentioned, but was a clear parallelogram of uniform width and height from end to end without any internal break, so far as the masonry was concerned—the roof, undivided by any chancel arch, ran clear from end to end, but the confines of the nave and chancel were clearly marked off by the closely-traceried screen which crossed the church at this point. This arrangement is well seen at Llanegryn. (Fig. 3.)

The abundance of wood screens in the West is very noticeable, and both in Wales and in Devonshire, districts retaining them in large numbers, they are associated with the type of church above described.

Those which survive are chiefly of the fifteenth or sixteenth centuries, two causes having operated to reduce the amount of earlier work.

In the first place—natural decay; in the second place, the removal of the earlier screens for the more extensive and complex structures of later times. The latter fact was observed and commented on by the late G. E. Street.

The very general rebuilding of West Country churches, or their enlargement by the addition of aisles in the fifteenth century, also accounts in a great measure for the disappearance of earlier work. This is notably the case in Devon and in Somerset, in which counties we may nevertheless find still a few excellent specimens of wood screen-work prior in date to the fifteenth century. That at Wellcombe, in Devon, may be considered very early. It is simple and rough in execution. The parcloses at Ottery St. Mary are of massive fourteenth century type, also the older screen at Mere, in Wilts (not the present rood screen).

Later we find screens such as those now arranged as a parclose in the church at Bridgewater, in which the work is still of a massive type, exhibiting features akin to stonework detail. Wood detail begins as an imitation of stone, and in its earlier periods is extremely massive, comparatively coarse in execution, though sometimes wonderfully undercut after the manner of freestone, but gradually we find

FIG. 3.

SCREEN AT LLANEGRYN.

it exhibiting more refinement of character and skill in execution, the design becoming more easy and natural, and the proportions lighter and more closely adapted to the nature of the material, and expressive of its qualities. We can discern this progress in viewing the detail of the parclose screens at Halberton, and the chantry screen now standing in the south transept at Dunster.

In the period of mature design which we are now approaching, it may be claimed that there is a very perfect and intimate correspondence between the character and detail of the West Country wood-work and the nature of the oak in which it is wrought, there being a virility and forcefulness in the design, and a "verve" in the execution which are highly suggestive of the vigour of living forms, and have therefore great interest and value to the artist or art student.

This quality is by no means so well developed in other districts—or parts of England—where the detail is too often merely imitative of stonework, and exhibits a comparative weakness and poverty of design, features of a harsh character, and possessing little interest, such as buttresses, battlements, water tables, and others of a like order, which are proper to stonework, being reproduced on a minute or attenuated scale, with much repetition. These features are apt to give a hard and mechanical feeling to wood-work, a feeling which is increased when the mouldings employed are hollow, or angular, but which can be greatly modified by a judicious use of foliage forms and enrichments.

The West Country work is distinguished not only by the absence, to a large extent, of these mechanical and imitative features, but also by the universal employment of convex mouldings, beads or ogees, which are destructive of any tendency to harshness of effect, and bold convex profiles in the scrolls and vignette enrichments.

But in the earlier wood-work some imitation of stone is only to be expected seeing that the arts of joinery and wood-carving were in process of development in England during the thirteenth and fourteenth centuries, and only reached their climax in the early fifteenth century, after the period at which stone-work had attained its best development.

We may now turn to the form of the earlier screens. Most of the wood screens of the fourteenth century would appear to have supported a loft or gallery to the westward, or centrally over the screen. The screens themselves have horizontal framed heads and the loft would have had a flat soffit. (Fig. 4.)

There are several such early screens in Devon—as Wellcombe, Braunton, Budleigh, &c. That at Stoke-in-Teignhead (Fig. 4), is said to date from Richard the Second's reign, and until its restoration it supported a narrow gallery. The little screen at Culbone probably upheld a similar gallery, and there are others of these square-headed early screens in Somerset, at Pawlett and Huish Episcopi, the latter said to have been removed from Enmore, whilst the northern part of the country is full of screens or remains of screens of a peculiar, and, I think, later type, of which Priddy, Wellow, or West Pennard churches afford examples. These consist of a number of narrow vertical divisions having narrow lights, square-headed, and containing tracery with crocketted canopy heads to the lights.

The galleries over the screens of this class were probably raised upon a coved soffit, as we see at Christian Malford, Ashchurch, and elsewhere.

In Wales, we meet with many screens of the Llanegryn type, carrying wide lofts with flat soffits, placed centrally over them, and sometimes supported, as at Llanwnog, by legs at front and back. Next comes a more elaborate type, which has arcading within a square head, as at Exbourne and Bow in Devon, and Keynsham, Ashton, and Wrington in Somerset, and in these the loft in most cases stood centrally over the screen supported by coving back and front. Lastly come the magnificent groined screens for which Devon is so famous, and these mark the climax of the art. The development of the groining compares very favourably with any specimen to be found in other parts of England, or with foreign screens; and the character of the ornamental detail, especially the vignette enrichments in the cornice, leaves little to be desired in point of excellence of design and execution.

The cornice enrichments here reproduced are from the screens at Atherington, North Devon. (Fig. 5.) I show a slide of the fine screen which stood in the church of St. Audries' West Quantoxhead, Somerset, before the rebuilding fifty years ago, and the fragments of which are now in the possession of Sir Alexander Acland Hood, by whose courtesy the author was permitted to take the photographs and measurements of the work.

The screens in the West Country are usually of great width, frequently being continued across nave and aisles from north wall to

south wall, whilst there is every evidence that the rood-lofts ran the whole length of the same. The screens generally exhibit a series of section, with moulded ribs and embossed or traceried fillings. Above these comes the beam which carried three or four tiers of

FIG. 4.

SCREEN AT STOKE-IN-TEIGNHEAD.

fenestrations with arched heads, subdivided by moulded standards supporting a close reticulated head of "perpendicular" tracery, and between these spring groinings of hexagonal vignette enrichment, divided by plain or twisted beads, and enriched by crestings at top and bottom, a choice and often highly ingenious design.

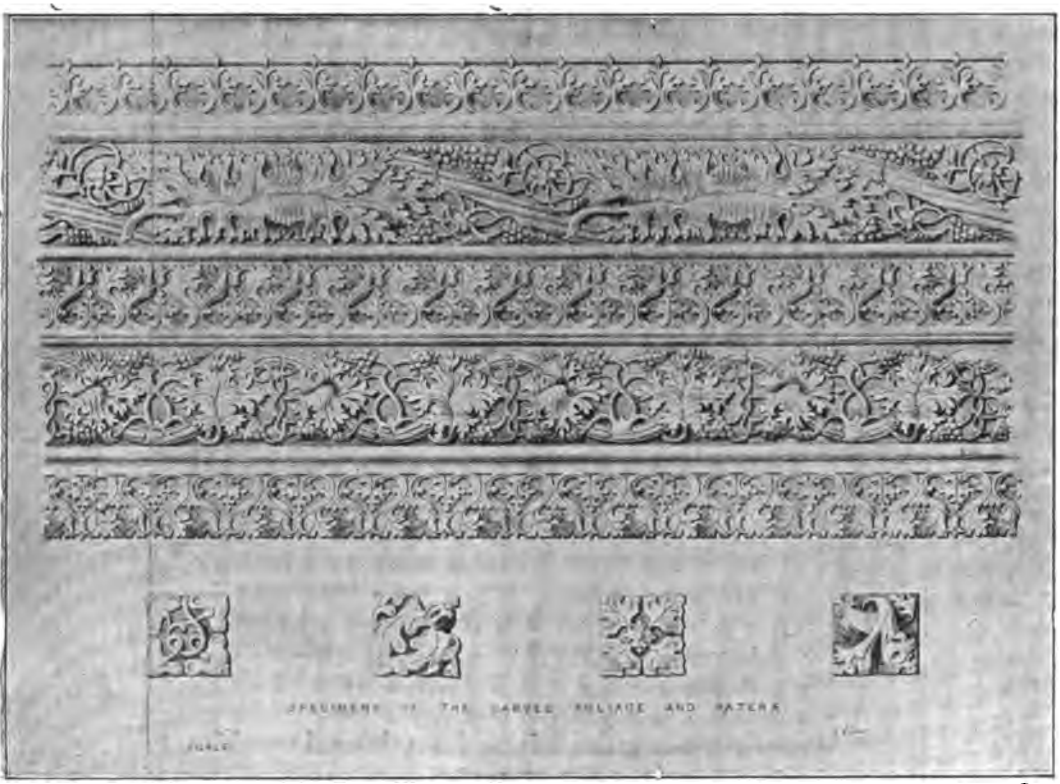
It is interesting to trace the types ruling in the different localities of the West Country, as these exhibit some totally distinct schools of design. Those of Devonshire were roughly classified by the author of this paper, in the Devonshire Association Transactions for 1903.

There are several leading types of work purely English in character, of which those of Kenton, Kentisbere, and Hartland may be singled out as representative specimens; In the case of Kenton there is a screen of which the whole framework and most of the detail are English, while small portions betray a Flemish character.

Italian detail is found at Marwood (Fig. 6), Atherington, and elsewhere in the fillings of the groining, whilst at Aveton Giffard (Fig. 7) and Kingsbridge we have a French type.

There are a group of screens in Mid Devon, at Colebrooke, Coleridge and Brushford, which

FIG. 5.



ATHERINGTON CORNICES.

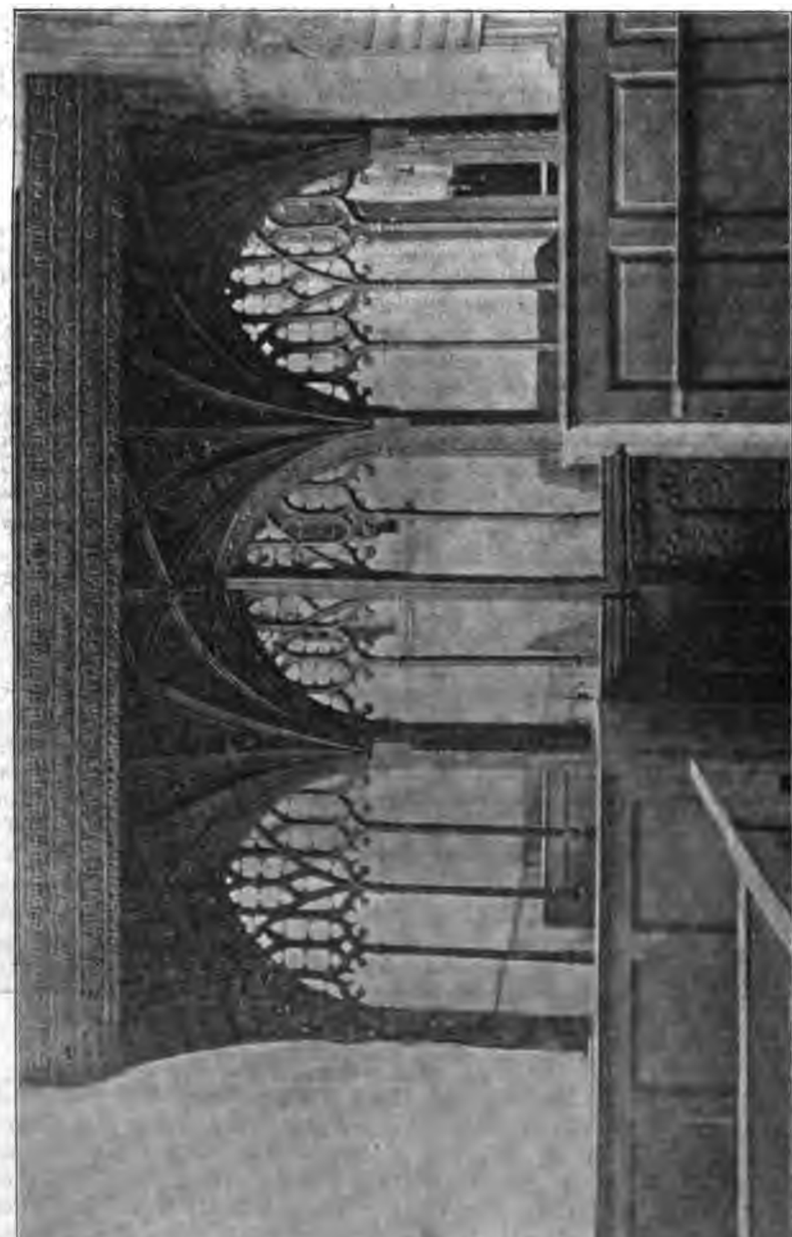
whilst at Swymbridge and Bridford we find a highly enriched variety, literally encrusted with carving, and differing widely in detail from the usual type. Somerset gives us a series of great dignity and distinction of character in the tall transomed screens at High Ham, Queen Camel, Mere, and others: whilst occasionally, as at Fitzhead, we find a screen entirely unique.

There are also a large number of screens, chiefly, I think, of late date, in which foreign detail is conspicuous, and in some of these there seems to be actual foreign workmanship. have a character akin to the French *flamboyant*, but with a curious Moorish or Oriental feeling about them. The tracery is subdivided, there being a main order of flowing or reticulated design, filled with a minute fretwork of similar form. A screen at St. Fiacre, in Brittany, exhibits detail closely analogous to these.

The English fifteenth century type conforms to the "perpendicular," but in some late cases there is a tendency to a debased decorated type of tracery, with detail coarse and ill executed. This appears in the parclose screens

at South Milton and West Alvington, both, I think, very late work. The Cornish work partakes of this nature, the tracery of the St. Buryan screen showing it; also that at St. Ewe. Unfortunately, Cornish screen-work has mostly disappeared as the result of nineteenth century vandalism.

Fig. 6.



Screen at Marwood.

The gallery fronts which surmounted the beam were of extremely rich design, and on them resources of the wood-carvers', painters', and gilders' crafts were expended, producing an effect of great magnificence.

The usual arrangement seems to have consisted of a series of panels, sometimes pierced with tracery, sometimes embossed, but for the most part painted with figures of saints or Scripture subjects, those in Devonshire following as their prototype the jubé in Exeter

Cathedral, which exhibits a series of Old and New Testament subjects. These panels would be surmounted by canopy heads of the finest tabernacle work, and divided enriched standards, as we see in the old gallery at Atherington and restored rood-loft of Kenton or Staverton. At the top there would be a running ornament with a tall cresting over it.

These paintings would have afforded a valuable means of instruction for the unlettered rustics of former times, and have been termed "The Poor Man's Bible."

An illustration is given of the screen and loft recently erected at Lew Trenchard, for the Rev. S. Baring Gould, in which the author has endeavoured to reproduce this ancient feature. (Fig. 8.)

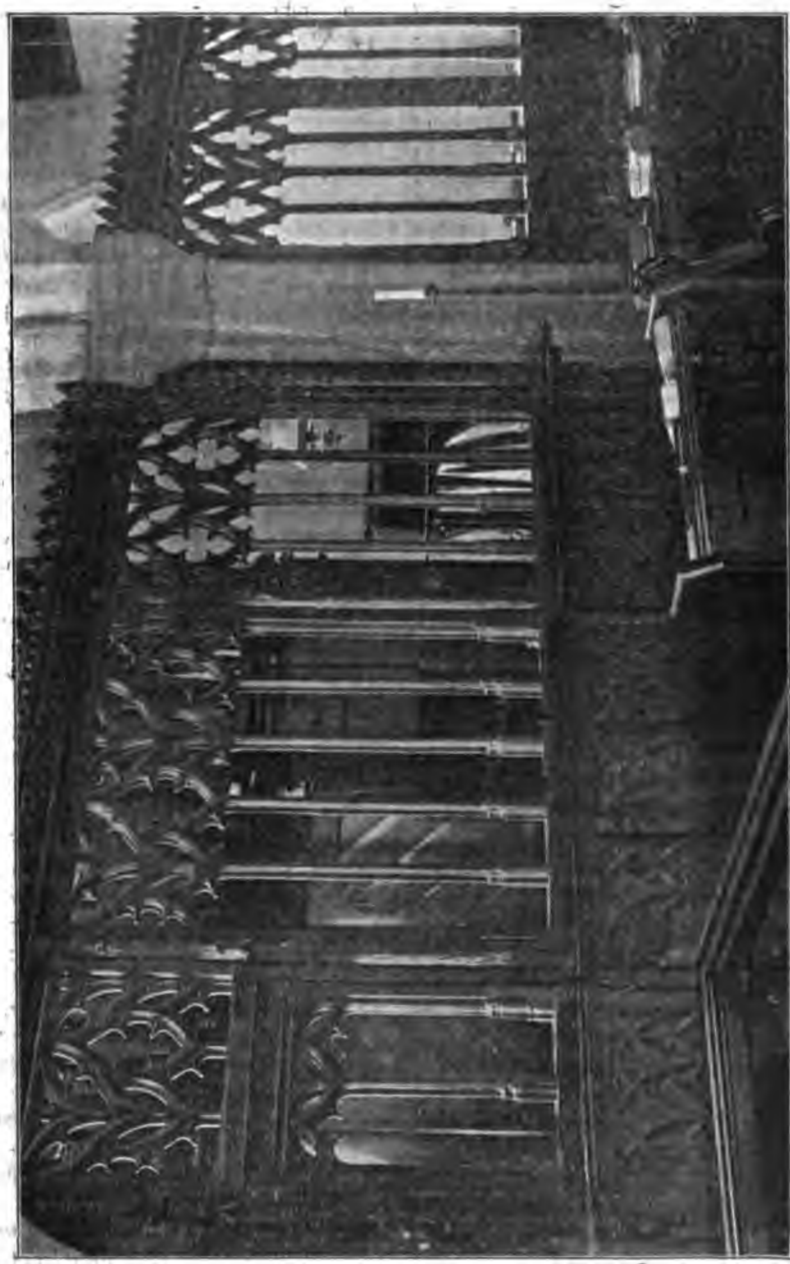


Fig. 7.

Screen at Aveton Giffard.

Much fine work remains in Wales where the rood-lofts have survived in many cases and exhibit some remarkable detail. Those at

Llanegryn (east side), Llanwrog, and Llangwm are typical specimens, having pierced traceried panels. Few remains of rood-lofts in Devonshire at the present date. Atherington, the best preserved, retains both balcony fronts, nothing having disappeared, but the statuary or original paintings, which have been replaced by heraldry, scrolls, and inscriptions of Elizabethan date.

Another at Marwood was taken down within living memory and several more are known to have been standing at no very distant date.

The balcony over the eastern side is still standing, however, and is a quaint and curious piece of work, evidently of late date, the panels being filled with rudely-carved grotesques.

The rood-lofts which, prior to the Reformation period, had been employed for numerous purposes, mostly of a nature afterwards judged to be superstitious, appear nevertheless to have fulfilled a special function of more lasting importance in providing accommodation for choir and organist, with perhaps other musicians.

In this use they were frequently confirmed, it would appear, after the Reformation, being extensively used for the purpose, and no doubt many only disappeared because they were worn out. The order of Archbishop Parker that the rood-loft fronts should be taken down as far as the beam and finished with a convenient cresting was generally, but by no means universally, complied with, and this was especially the case in Devonshire where a great many were retained as singing galleries or pews, as at Tiverton, Cullompton, and Totnes, whilst others were simply removed to the west end of the church. It has been considered that the order for their removal was not aimed at the lofts, as lofts, so much at those superstitious accessories, which were often a part of their structure, and thus necessitated in many cases the demolition of the entire fronts.

It seems odd that whilst the paintings or sculptures over the screen fell under such complete condemnation in Edward VI.'s and Elizabeth's time, the figure paintings which adorned the lower panels of the screens were not ordered to be destroyed. Such mutilation as they have received appears to have been chiefly at the hands of the Puritans, and many series of such figures yet remain in Devonshire, as well as East Anglia, to gladden the heart of the antiquary. These paintings have been ably and exhaustively dealt with by Mr. C. E. Keyser, F.S.A. ("Archæologia," vol. lvi., 1898).

There was a strict injunction that the screens themselves were in all cases to be retained, and we find that not only were they not destroyed at the Reformation, but a great many were erected during the Reformation period and subsequently these may be classed in order of date as the sixteenth, seventeenth, and eighteenth century types, illustrations of which are given in the screens at Lustleigh, Rodney Stoke, Washfield, Low Ham, and Cruwys-Morchard. The screen at Lustleigh shows the Gothic traditions in its general form and detail, but with altered features according to Reformation ideas, figures of choristers and clergy being substituted for saints on the lower panels. That at Washfield illustrates the Jacobean type, in which a greater departure from old models is of course noticeable. In the screen at Rodney Stoke we see the effect of the revival of Catholic ideas under Archbishop Laud, there being here a Post-Reformation loft above a screen of the same date (Fig. 9). Other fine types of post-Reformation screen-work may be seen at Croscombe, Crowcombe, and Bridgwater.

The attempt to reproduce some of the characters of fifteenth century enrichment is noticeable in the cornices, but the immense difference is apparent, the seventeenth century imitation being flat, coarse, and superficial, and yet having a by no means ineffective character. It illustrates, however, the great decadence in the native arts since the days of the Tudors.

The example from Low Ham is even more interesting, as here is a church with internal fittings complete, in Caroline Gothic. The screen is well worthy of study. At Cruwys Morchard we see one of the instances—few in number—of a screen with parclose, stalls, &c., erected in the Hanoverian period. This was an age of apathy in church matters, when old landmarks were in process of being forgotten; and although such instances as this exhibit a continuity of old tradition, yet, as far the characteristics of West Country screenwork are concerned, this work cannot claim to be a successor, as it is purely Italian in design.

The West Country type of church having as a rule no chancel arch, its place was usually taken by a partition extending from above the screen to the apex of the roof. There are good ancient instances of this at Bettws-Newydd, and at Mitchelddean, whilst Littleham (Bideford) provides a modern one. This may be called a tympanum of the screen. On this it was customary to depict the Doom, and

FIG. 8.

SCREEN AT LEW TRENCHARD.

FIG. 9.

SCREEN AT RODNEY STOKE.

against it or in front of it, on the western side, would stand the Holy Rood with figures of St. Mary and St. John.

At the Reformation these tympana were despoiled of their superstitious paintings and their surfaces were whitewashed or plastered, and the tables of the Law, with the Royal Arms, the Creed, and the Lord's Prayer attached to them in accordance with the decree of 1604. Illustrations of these tympana are given from Llanelieu, near Brecon, an ancient and unaltered example; from Wenhaston, showing the Doom—next, a Post-Reformation example from Bridestowe with a painting of the Resurrection; and from Parracombe, shewing the usual Post-Reformation tablets together with others, but it is to be regretted that during the earlier "Restoration" period in the nineteenth century, the greater part of these disappeared, being considered an obstruction by the clergy of those days who had lost sight of the old traditions and failed to see the necessity of a barrier between nave and chancel. Much mischief also has been done by the hasty and injudicious repair of screens, and to save the cost of restoration they have frequently been cleared of their ornamental detail. Sufficient nevertheless remains to form an artistic storehouse of the greatest value, and it needs but a careful and attentive study of the West Country screen-work to demonstrate its very high importance to those who are seeking to revive those beautiful handicrafts which were the pride and joy of our forefathers, but which has since fallen so lamentably into abeyance.

In these beautiful compositions we find a richness and variety which cannot fail to satisfy, combined with a remarkable honesty of design, and all the freedom from affectation which differentiates a native from a borrowed style. They remind us of those ineradicable principles in art which connect the form and proportions of a design with the nature of the material in which it is wrought, and regulate its character in truth, fitness, and harmony, offering in these respects, it may be feared, a rather painful contrast with much that unfortunately distinguishes modern compositions—especially those of a school which aims at emancipating itself from ancient rules.

DISCUSSION.

The CHAIRMAN thought the paper was a most able and interesting account of the old screens in the West of England churches. It not only dealt with the history but also with the art of the subject. The running vine patterns were full of beauty. He had examined some of them and might remark that he had some delightful carved fragments of them in his office which were given him by the late Lord Devon. They were almost always gilded on red which gave a warm tint. There were two very different ideas of the interior of a church. The one was to have it all open to view, so that it might appear spacious and grand, and present an uninterrupted vista. That was the classical, and is the modern idea. The Gothic plan is the opposite to this. Here the interior is screened and we have the conception of mystery—an indefinite space beyond. A dark screen may stand up against a bright golden east end. If Nature was to be the guide in art, there can be no doubt that the screened effect is the one most in accord with it. The Chairman further said that he remembered walking on a road that wound its way half up a great hill that rose out of a vast level landscape. Between him and this wide view of long stretching land there were trees standing, screenlike, with their high stems, and the tracery of their branches. They stood out dark against the background of the vast stretch of land that was bathed in sunlight. Presently, as he walked on, the trees came to an end, and all the broad low-lying land was displayed to his eyes. The view was fine, but the entrancing beauty—the mystery of a half-seen view was gone. The poetry was turned to prose, and the richness of effect to comparative poverty. With the less seen view of the plain, the effect was one of indefinite, well nigh an infinite appearance of space and distance. But when all was seen there was a loss—a loss even of size and distance. The half had been greater than the whole as it often is in Art. Here then was the screen system as contrasted with the unbroken vista idea. How far more beautiful the screened scene was than the open one no words could express. While he was familiar with a few of the sreens that had been exhibited, he was a little sorry that more of the Eastern counties' screens had not been shown because he knew them best. The screen at Southwold was a great work of art. It was rather interesting that in that church there were two screens, the centre screen, and the screen at the side, which were entirely different. The centre one, which was a little earlier, was full of art, while the other was rude. He was sorry to have to say that he believed the painting on the centre screen was Flemish work and was almost worthy of Van Eyck or Memling; the painting on the side screen was English and was very rude and elementary compared with the Flemish work. He had much pleasure in proposing a vote of thanks to the author for his most valuable paper.

Mr. C. E. KEYSER thought the feeling which would be uppermost in the minds of the audience would be one of astonishment at the magnificence of the carving of the screens exhibited. There was no doubt that the screens of the West of England excelled most other work of the kind for the beauty of their

carving. He knew the eastern counties' screens well, and did not think there was anything in Devonshire which could compare with such screens as those at Ranworth, Southwold, Attleborough, and many others, but there was a certain special character about West Country screens which struck him as most peculiar. The Somerset screens he considered were more of the pure English type, and he did not regard them as so remarkable as the Devonshire and a few of the Cornish screens. There was a great question to his mind as to what was the influence which prevailed to bring about the carving and erection of so many screens within so very limited a period. He differed from the author in regarding a particular screen shown as of the fourteenth century. Although it was a variation of type, he thought it came within the period in which almost all the screens in Devonshire were carved and painted, which began about 1480 and went down to post-Reformation times. It was wonderful how the people of the little churches all round Dartmoor and all over Devonshire could have afforded to get men of genius to carve and paint the screens which were put in their churches. He was not prepared to think they were done by foreigners; he was one of those who liked to feel that in all times Englishmen were able to hold their own. There was no doubt, however, that, in Devonshire in particular, there was a foreign influence with regard to the screens, and this was shown more in the painting than in the carving. He had brought with him a number of drawings, which were made for him when he read a paper before the Society of Antiquaries on the subject of the figures which were painted on the screens. There was almost as much to be said with regard to the painting on the panels of the screens as of the wonderful varieties of their carving. If the figures were inspected, it would be seen that there was a certain foreign influence about them. Both the screens at Chudleigh and Bovey Tracey had figures of the Apostles and Prophets alternately, a subject which was found elsewhere in England. A great many saints were found represented on the Devonshire screens which were most difficult of identification. He went thoroughly into the subject about ten years ago, and managed to identify almost every saint which occurred on the panels of the screens. There were many saints portrayed who were much more popular in France than in Spain, Italy, or England; and as these were not found on the screens in the eastern counties, or elsewhere in England, he thought it might be said that at any rate, with regard to the people for whom the screens were painted, a certain amount of foreign influence was brought into play, and that possibly help was obtained from abroad in order to produce the subjects which were required for the different churches. He hoped they would be able to find out where the screens were made, by whom, and under whose care, because he could hardly believe that unless there was some special school of art at such a centre as Exeter, it would be possible for so large a number of magnificently carved screens to be produced within comparatively so short a time. The author had stated that the order that the screens were to be retained in the churches possibly explained why it is that so many still exist. There were a great many screens which were no doubt of post-Reformation date, and some of the paintings on them were of that date too. In Ugborough church between Totnes and Plymouth there was a screen with a painting of the Martyrdom of St. Sebastian, which occupied four panels of the screen; that was a subject which one would not expect to find in post-Reformation times. From the costumes in the painting there was no doubt they were executed at the beginning of the seventeenth century. Many of the screens had been subjected to cruel usage, had been either whitewashed or brown painted over; the paint had been afterwards scraped off, and some local artist thinking he could put the thing right had re-painted the whole series. That he thought was the case at Dartmouth and in the Church at St. Mary's Steps at Exeter. There was no doubt that local people had embellished some of the screens; they had managed to get the various washes off, and had then thought the right thing would be to paint the figures up, but as far as he had been able to ascertain many of the figures had been painted to represent quite different people from what were there before. But there was a mystery about the whole subject. Within a comparatively small district there were hundreds of beautiful screens with very little variation in the date at which they were put in. It was said that Henry VII. exercised a very great influence in the West of England; in fact, almost all the churches and towers in Somerset and Devonshire were rebuilt during his reign. There must have been a wonderful enthusiasm among the people, and they must have been very prosperous to have been able to rebuild nearly the whole of the churches in the western part of England and erect such beautiful screens. He felt most grateful to the author for having brought such an interesting subject before the Society.

Sir CHARLES KENNEDY, K.C.M.G., cordially agreed with the Chairman's and Mr. Keyser's remarks as to the excellence of the paper and the admirable way in which the subject had been presented. It was a very remarkable thing that within the space of about seventy years, such a large number of screens should have been erected in village churches in rather a remote part of England, which was not wealthy in the same sense as the villages of East Anglia were. It was possible that in the publication of the Diocesan Registers which was now taking place in Exeter, some light would be thrown by means of the authority given for the rebuilding of the churches and the erection of the screens, on the circumstances under which they were carved. If any member should happen to be staying in that part o

the country, with Exeter as the centre, there were several screens which could easily be seen on the North Devon line. For instance, there were the screens at Atherington, Kingsnympton, and Lapford, which were quite easy of access from railway stations. In South Devon, to the south-east of Exeter, there was the screen at Littleham, and further to the east the screen at Talaton, which was considered one of the best in Devonshire. To the south-west there were the screens at Kenn and Kenton, and on the borders of Dartmoor, three miles from Bovey Tracey, there was a remarkable screen in the church at Ilsington. As the author of the paper had stated, the peculiar fact was that most of the screens were of oak; he did not think there were more than ten stone screens in Devon. Very good examples of painted screens were to be found at Chawleigh and at Chulmleigh, two miles from Eggesford station. An excellent list of Devonshire screens was published in the paper which Mr. Harry Hems read before the Society of Architects on April 21st, 1896, and that gentleman had in his gallery at Exeter a collection of fragments of screens and of ecclesiastical woodwork, which he was always ready to show, and which embraced examples not only of present screens, but work which was now no longer to be seen in its entirety. When work of restoration was done, very often imperfectly, pieces were sometimes considered not to harmonise with the main part of the woodwork of the building, and were very ruthlessly cut away, and in that manner the continuity of ecclesiastical woodwork had been lost. As he lived in the county, he wished to say he had learned much and received great pleasure from listening to the paper.

Mr. Lewis Day, in supporting the vote of thanks to the author for his extremely interesting paper, said that with regard to the Renaissance character of some of the screens, the author seemed to argue that because they were of that character they must have been done by Italian workmen. That might have been the case in some instances; but he did not think it was necessary to imagine that Italian workmen were employed in order to explain the Italian character of the design. At that time the Renaissance detail was abroad; people were bitten by it, and pattern books of Renaissance designs were common. There was no doubt that the carvers of that period had those pattern books, and tried to do something Italian; and it would be noticed that the Renaissance character of the screens had a decidedly Gothic twang about it. It looked to him as if it was the work of Britishers trying to be Italian. The author had shown a screen from Colebrook which he suggested might be French. There was not the slightest doubt in his own mind that that screen was Spanish work, although it was impossible to explain why. He had been particularly interested in the tracing described by the author as minor and major, and also in some of the Welsh work, but he did not quite follow him in his remarks with regard to the return to the Decorated style in some of the Perpendicular work. It did not seem to him to be returning to Decorated work at all, but simply a lingering of the geometrical element which was the beginning of the Perpendicular. The great thing which struck him in regard to the work shown, generally, was the admirable simplicity of the carving and its comparative rudeness. Allusion had been made to the perfection and grace of the carving. He did not find the grace of it so prominent; there was a perfect mastery of the tool, and vigorous, manly workmanship, rather than refinement; and, if it was examined with a strict artistic sense, it proved very often to be overdone. But there was the beauty of vigorous, rude, simple work which any practical carver might have done, given the tradition of design. Somebody had asked how such work could have been done. He thought it was really the tradition that helped people to do the work; they did not bother themselves about originality, they simply went on doing the thing that was natural to them. It was tradition which enabled the work to be done; and where present day people were going wrong, was in dropping away from all adherence to tradition.

Mr. E. F. Strange, in referring to Mr. Day's remarks in regard to the want of grace in the carving of the screens, said the author had not shown a specimen of what he (the speaker) considered to be absolutely the finest wood carving in the whole of the West of England. He had ventured to bring with him a slide of the screen which was in the church at South Pool. From the view it would be seen that the carving must have been done by a man of great skill. It was completely under-cut; and local church decorators, who used the screen for the purpose of harvest festivals, had no difficulty in tying string round the tendrils for the purpose of hanging up flowers. With regard to the question of foreign influence, the author and various speakers had suggested that that influence had been Flemish, French, Italian, Spanish, and Moorish; but although traces of those influences had been pointed out in a few screens, he was not sure that anything more than casual and local coincidences had been proved. Every screen which had been shown had a skeleton of English work. The general plan, the framework, and all the setting was English. He would like to know whether it was suggested that two or three foreign carvers from different countries came over to England and executed small portions of the screens. Mr. Day had suggested the solution of a problem which the author considered difficult. He did not think it was necessary to look abroad for artists who made or decorated any of the screens in England. Pattern books were obtainable; the art of engraving was well established, and engravings were obtainable. But there was something more, which had not before been alluded to, which was not only obtainable, but was pro-

bably in existence in the majority of parishes in the country. The churches were well provided with funds at that period, as was proved by the frequent re-building of them, and the richness of their decoration; and there was hardly a church which did not possess finely illuminated books, which came from the continent in large quantities, although there was good writing and illumination done in this country. He ventured, therefore, to suggest that the theme of the work was often supplied to the local worker from the illumination of such a book; and that if it was not actually supplied in that way it was indicated to him by a foreign monk in one of the monasteries. He did not think the work was done by the monks, although it was extremely probable they might have suggested to a carver here and there themes which eventually became part of the tradition, and were handed on by him to his sons and his associates. In connection with the South Pool screen there was almost evidence of two generations in the three or four screens of the same kind that existed in the neighbourhood. He was glad to hear from Sir Charles Kennedy that Mr. Hems, who had restored many screens in his time, possessed a considerable gallery of fragments which he was willing to show to visitors to Exeter. He asked the audience whether they thought it creditable that a private gentleman should possess a gallery of such fragments, and that they should be grateful to him for being willing to show them, while none of the national museums possessed a single specimen.

Mr. H. LONGDEN stated that he had had the pleasure of visiting the church at Lower or Nether Ham, the screen of which had been shown. It was not the parish church, but a chapel situated in the middle of a field, without churchyard or enclosing wall, and belonged to the Lord of the Manor. The building is entirely of the date of Charles I., being in the imitation of Gothic which was done at that period. The screen was very interesting. The ornament and cresting were Renaissance, and the tracery was an amusing attempt at Gothic. He had inspected the screen at Holbeton in Devonshire with Mr. J. D. Sedding, and that gentleman was quite persuaded that the carving in the screen was Flemish. He did not wish to imply that the work on many screens should be attributed to foreign workmen, but he thought Mr. Sedding's judgment was worthy of attention. He wished to add his tribute of thanks to the author for his most interesting paper.

A MEMBER said he would like to remark with regard to the supposed unlikelihood of artistic workmen coming to this country in the early days, that it was well known from the history of Westminster Abbey that the monument of Edward the Confessor was ornamented somewhere about 1300 or 1308 by artificers who came partly from Venice and partly from another town in Italy. There was no doubt that artistic masons travelled all over the country in the early days, at all events in Scotland, which was proved by their work in the Roslin Chapel. He mentioned that fact to show the likelihood of artists moving about the country for the purpose of decorating screens, just as they decorated tombs.

Miss ROWE said that Mr. Day had expressed the opinion that the Colebrook screen was Spanish. She spoke with diffidence as she had never seen any Spanish geometrical tracery, but having seen and studied the Colebrook screen with very great care, she thought it was undoubtedly French. The way in which the little columns in the lights were carved was a very characteristic feature of the late fifteenth century French Gothic. Not one of the little columns in those days had the same pattern; there was a great variety in the twists and scales. That also applied to the Coledridge screen, which was on very much the same lines as the Colebrook, although it was not such fine work but rather coarser. In regard to what Mr. Strange had said, she thought with him that of the screens she had seen, the South Pool was the finest. It resembled very largely the screen at Dartmouth, and in her opinion the Portemouth screen came next with regard to beauty. In both these two examples the influence of the Celtic interlacement was very remarkable. Mr. Strange had referred to the under-cutting of the South Pool screen. From a practical worker's point of view she did not think the under-cutting was so wonderful as that gentleman thought. The carving was cut on a convex moulding about five-eighth inch thick, and she thought she had noticed some of the sections of the mouldings carved shown on one of the slides; therefore the back could be got at quite easily; the tools could drill the holes between the interlacements, and when it was carved it was fixed up on to a concave moulding. From the sections she examined in Devonshire she found that that was the principal treatment adopted in the fine screens which looked so elaborately under-cut. The question of the dates of the screens was a very perplexing one, and she would like to ask the author if he thought they ought to go by the paintings on the screens for the dates. It seemed to her that the paintings might be later than the woodwork, and might have been done *in situ* when the screens were put up. She thought with Mr. Strange that the construction of the screens was essentially English. She had never seen anything to beat the carving of the principal member of the South Pool screen. It was quite possible that foreign workmen might have done some of the work on the Atherington and Lapford screens, but she felt perfectly certain that the screens were English, although details like the paintings and some of the Renaissance carvings might have been done by foreigners; in fact, she even went so far as to suggest that the Renaissance ornament might have been filled in after the

general scheme was carried out. All students of woodwork were greatly indebted to the author for his very interesting papers read at the Devonshire Association, and for what was even more valuable, his splendid catalogue of the churches with reference to the literature in regard to them, that he gave in his second paper. She was also extremely grateful to the author for the excellent paper he had read.

Mr. BOND, in reply, said that with regard to the origin of the foreign features of the screens, it must be conceded there was great probability that a good deal of the foreign patterns might have been taken from foreign books, or, more probably, from illuminated manuscripts. In all screens in connection with which there were no facts to go by they must take the most probable argument. They knew that such books existed, which would have furnished a sufficiently clear pattern to go by, and therefore they might well have been copied. At the same time he had always felt a lingering doubt, although he should like to believe that English workmen executed the screens. The reason why that seemed to him most probable was that he found on one of the screens, notably the one at Kenton, there were two very different classes of work. First of all, there was the foreign work, which he was sorry to say was very much better executed than the English work by the side of it. It was evidently the work of entirely different individuals, and it seemed to him as if some Fleming or foreigner had been brought over to coach the other workmen and to give them a lead. With regard to the work not being monastic, Mr. Hems was responsible for the saying that at least one of the screens in Devonshire was reported to be the work of the monks of Tavistock, namely, the screen at Abbots Kerswell. He was very glad that Mr. Strange had shown a photograph of the South Pool screen, because he agreed with that gentleman that it was one of the finest specimens; but the same thing was shown at Manaton, which exhibited in a marked degree a similarity to the Celtic treatment. Mr. Strange also stated that the framework of the screens was English. He fully agreed with that remark, the foreign features simply come in in the small details. He was glad to find that Miss Rowe supported his view that the Colebrook screen was French. The screen at Coledridge enclosed a chapel to the memory of Sir John Evans, a knight who fought in the French wars, and there was therefore a suggestion that he might have been in touch with French workmen. He would rather leave the question as to whether the paintings were an aid to ascertain the dates of the screen to an acknowledged master of the subject like Mr. Keyser. The Renaissance work on some of the screens was very possibly filled in; he found in one or two cases it was on a hard plaster on the face of the woodwork. In conclusion he thanked the audience for the kind reception of his paper, and for the support he had received from the various speakers in the discussion.

Mr. PHILIP NEWMAN thought their thanks were due not only to the author for his valuable paper, but also for the additional information which had been contributed to the discussion by the Chairman, Mr. Keyser, Mr. Strange, and others.

The CHAIRMAN said he would like to support one remark Mr. Day had said, namely, that all art was and must be founded on art that had gone before. Mr. Day had mentioned tradition. Tradition was a great principle. People saw something done, and said they could improve on it; that improvement was an advance, and from that they built up the great tradition in art. It came down from the Egyptians through Greece, and by one vast procession, as it were, eventually came to these islands. Nowadays, he was sorry to say, there was too much tendency, especially among the younger members of the profession, to ignore tradition and say they must have something new. That was the destruction of Art. If a young designer or artist produced something new, some people said it was wonderful, and they had never seen anything like it before; but they did not pause to consider whether it was beautiful, graceful, or dignified. Provided it was new it was sufficient for them; but he was sorry to say that the ugliest things were achieved by this "new art."

SIXTEENTH ORDINARY MEETING.

Wednesday, March 29th, 1905; R. C. MUNRO-FERGUSON, M.P., in the chair.

The following candidates were proposed for election as members of the Society:—

Arnold, W. Hacker, Messrs. H. Whitlock and Co., Holland-gate, Kensington, W.

Gibbons, William Pike, J.P., C.C., Ruiton-house, Upper Gornal, Staffordshire.

Habibullah, Khan Bahadur Md., Vellore, North Arcot District, Madras, India.

Henley, Mrs. A. L., 7, Oxford-square, W.

Jack, Stuart Maclean, 42, Victoria-road, Upper Norwood, S.E.

Jackson, Walter Geoffrey, Prestwick, near Witley, Surrey.

Macdonald, David Baird, F.C.S., 127, Evington-road, Leicester.

Ridley, Frank R., 10, Russell-street, Covent-garden, W.C.

Scholes, William, A.R.C.Sc., F.C.S., 102, Victoria street, Radcliffe, Lancs.

Taylor, Thomas, Rosendale, Newcastle-under-Lyme.

Wilkinson, Henry Ernest, 31, Priory-park-road, Kilburn, N.W.

The following candidates were ballotted for and duly elected members of the Society:—

Carley, Geo. C., 14, Dingwall-road, Croydon.
Cuff, Herbert Mackenzie, E.Ex. A. and C. Telegraph Company, Singapore.
Davies, John Samuel, 9, Clifton-road, Newport, Monmouth.
Dowson, Ernest Alfred, 45, Newhall-street, Birmingham.
Flood, W. H., 1, Northbrook-road, Ilford, Essex.
Parrott, Lieut.-Col. Thomas Samuel, Exploration-buildings, Johannesburg, Transvaal, South Africa.
Prain, Robert P. F., M.Inst.M.M., care of Messrs. Jackson Brothers, Iquique, Chili, South America.
Sabnis, Rao Bahadur Raghunath Vyankaji, Kolhapur, Bombay, India.
Sparks, Hubert Conrad, Suffolk-house, Putney-hill, S.W.
Staver, William H., Casilla 336, Guayaquil, Ecuador, South America.
Thompson, Henry Yates, J.P., F.S.A., 19, Portman-square, W.

The paper read was—

BRITISH WOODLANDS.

By the Right Hon. Sir Herbert Maxwell, Bart., M.P.

I come before you to-night rather in the spirit of a converted criminal than in the hope of telling you anything you don't know already. I hope that my presence here may be taken as evidence of the awakening conscience of land-owners to the opportunities we have missed, to the valuable source of income which we have squandered, and to the urgency for a reform in our system of forestry. I was brought up with an intense and sedulous love of trees; some of my earliest recollections are connected with the instruction given me by my father in what were, at that time, the approved principles of wood management, and I continued to act on those principles after I succeeded to the estate twenty-seven years ago. The result has been that, although I posssess a considerable extent of ground under trees, there is hardly any of it more than fifteen years old, which I should not be ashamed to show to one who understood the principles of forestry as distinct from arboriculture.

I have said thus much as preliminary, in order that too much may not be expected from me in the way of instruction. When Lord Mahon asked the Duke of Wellington whether his experience in his first campaign—that disastrous one in the Netherlands under the Duke of York—had been of any service to him, he replied, "I learnt what I ought *not* to do, and that is always something." Wellington, happily for his country, learnt his lesson while the best part of his life still lay before him. I have learnt mine at a period when Horace's lines have a peculiarly mournful significance—

> "With all the trees that thou hast tended,
> Thy brief concern is almost ended;
> Except the cypress—*that* may wave
> Its tribute o'er thy narrow grave."

Well, now, I have tackled a subject rather unwieldy to be dealt with in an hour's discourse, and I will try to confine myself to a few of the most salient points. I will divide it into two branches—First, what I conceive the State might do, with prudence and profit, to develop the national resources; Second, what private owners might do to develop the resources of their estates.

Since I entered Parliament 25 years ago two inquiries have been directed into this subject; the first, a Select Committee of the House of Commons, which sat 1885-6-7; the second, a departmental committee, which reported in 1902. No action was taken on the report of the first: of the result of the second we have more hopes, because we have now, what we had not in 1885-7, a Government department—the Board of Agriculture and Fisheries—to which has been committed the duty of promoting instruction in forestry. Among the many points upon which both these committees were in thorough agreement were these facts—(1) that "the world is rapidly approaching a shortage, if not an actual dearth, in its supply of coniferous timber, which constitutes between 80 and 90 per cent. of the total British timber imports;" (2) that there is a vast area, estimated in millions of acres, capable of growing timber of the finest quality; (3) that the climate of the British Isles is favourable to economic forestry conducted on a proper scale (not in grudging patches, clumps, and strips); and (4) that it requires only the exercise of timely forethought and a moderate annual expenditure to anticipate the time when scarcity of foreign timber shall have greatly enhanced the price, and to replace with British-grown timber much of those enormous imports upon which we depend at present.

These four points having been emphatically affirmed by the two committees, I need say nothing more upon them to-night; but there is a fifth point on which I venture to go a little further than the departmental committee, "We do not feel justified," says the report, "in urging the Government to embark forthwith upon any general scheme of State forest under present circumstances." Well, I have the teme-

rity, which the committee lacked, to urge strongly the wisdom of embarking upon a scheme of State forestry, and if I am blamed for that temerity, I make the same excuse for my scheme as served a certain young person who had added an unforeseen unit to the population—"Please, sir, it's only a very little one!". I only ask for the investment—the investment, mind, not the gift—of £10,000 a year, for the purchase and planting of suitable land.

No branch of agriculture, not even wheat

OAK HIGH WOOD, NEW FOREST.

FIG. 2.

SELF-SOWN OAK, ABOUT 30-40 YEARS OLD (UNDERPLANTED WITH BEECH), AT THORNBURY, GLOUCESTERSHIRE.

growing, has suffered such a slump in the last 25 years as hill sheep-farming. There are hundreds of thousands of acres in Scotland, once valuable sheep pasture, now rented at not more than two shillings an acre. From some of it, a good additional return, say a shilling an acre, is obtained for the grouse on it, but a great deal of it is unsuitable for grouse, but very suitable for growing timber. Such land is constantly being offered for sale. Twenty-five years purchase would secure 1,000 such acres for £2,500. If the ground is level, planting 3 feet by 3 feet will take 4,840,000 trees; the cost at £6 an acre, equals £6,000 for the 1,000 acres. On sloping or steep ground fewer trees will be required and the cost will be proportionately less. I make no provision for houses or fences, assuming that the farm is bought all standing, but £500 must be allowed for repairs and preliminary draining, making a total initial outlay of £9,000 on the 1,000 acres. The interest on the balance of £1,000 ought to pay the annual tool bill, and the annual wage bill may be reckoned at—

	£	s.
Head forester	120	0
Foreman	52	0
Eight woodmen at 18s. a week	374	8
Miscellaneous	103	12
	£650	0

Shall we be able to meet this charge, draw interest on the capital sunk, and hold our capital in hand at the end of 100 years? I think so, even allowing that for the first fifteen years not a farthing of revenue can be drawn from the plantation. By that time the £10,000 sunk will have increased at 3 per cent. compound interest to about £15,000. To secure 3 per cent. upon that sum and to defray the annual expenses of £650, we must show a net annual profit of £1,100 from the 1,000 acres. The returns ought to commence fifteen years after planting, beginning with pit props, for which there is an insatiable demand in this country, chiefly supplied from Norway and Sweden; proceeding to medium sized trees removed in thinning until the period of commercial maturity, which, in the case of Scotch pine and larch, should be reached in 80 or 90 years, when the regular falls will begin. Mr. Nisbet estimates the average annual yield of coniferous timber, Scotch and larch, at 75 cubic feet per acre. Assuming this to be a moderate estimate, and assuming that the price of such timber will not exceed 6d. a foot (an improbably low estimate) your 1,000 acres will be yielding a gross annual income of £1,875, that is, a revenue of 37s. 6d. an acre from land which, as sheep pasture, yielded a rent of 2s. an acre, or £100 from the 1,000 acres. The balance-sheet will show thus:—

Expenditure.		*Receipts.*	
Interest at 3 per cent. on £15,000	£450	Sale of 75 cubic feet per acre at 6d. on 1,000 acres	£1,875
Annual expenses	650		
Balance profit..	750		
	£1,875		£1,875

Supposing that for the next fifty years the State were to invest £10,000 a year in plantations, it would have made a progressive investment of half a million sterling—the cost of four days campaign against the Boers—yielding about 11 per cent. interest, and instead of a rural population of one shepherd to 100 acres of pasture, there would be one woodman to every 1,000 acres, or a total of 500 woodmen on the State forest of 50,000 acres, instead of 50 shepherds. No trifling consideration this in these days of rural depopulation.

There appeared lately in one of the evening papers a letter from a noble earl in reference to Mr. Keir Hardie's proposal for State forestry. His lordship declared that it was futile to think of profitable forestry in the United Kingdom for two reasons—first, because of the furious storms which sweep these islands at irregular intervals; second, because the timber produced in our woods is far inferior in quality to that grown on the Continent.

As to the first objection, I deny emphatically that we are more exposed to storm than, say, Norway or Sweden, whence we draw such large supplies of coniferous timber. It is true that we suffer far more from wind damage than is the case in continental forests, but that is the result partly of our custom of planting in narrow belts and isolated small masses, and partly of the mischievous system of overthinning which came into vogue in the nineteenth century. Trees that have been encouraged to grow heads out of all due proportion to their height will succumb to a storm that may be lifted harmlessly over a solid block of well-grown forest. A thousand *contiguous* acres of woodland will suffer far less from gales than 1,000 acres scattered over an estate of 10,000 acres.

Next, as to the alleged inferiority of British timber to continental. Surely that is a strange allegation against a country that used to supply timber for the noblest fleets that ever

put to sea. I may say in passing that the demand for ship timber had something to do with initiating our vicious system of over-thinning. Shipwrights did not want straight boles, they wanted bent timber; and you will actually find in old treatises on forestry instructions about tying down the limbs of oaks to produce the desired contortion. The result has been that we have conceived and aimed at a false ideal. Our notion of what an oak ought to be is framed upon such a magnificent deformity as the "Major" oak in Sherwood Forest.

That we can grow fine straight oak if we choose may be seen in this example from the New Forest, a domain which, unhappily, the State is not permitted to treat on right principles. Here again is a wood of self-sown oak at Thornbury, in Gloucestershire, 30 to 40 years old, which promises to develop into splendid clean timber. But to obtain examples of the highest development of oak timber, we must go to France. Here are a couple of photographs showing the last stage—the final fall—of a forest of sessile-flowered oaks in a French forest.

Now that we want straight, clean timber, there is no country in the world better able to produce it than our own. Ah but, says the timber merchant, your firs are grown too fast. British deal cannot compare with Scandinavian, which is grown much slower. True, but here again the evil comes from over-thinning. Grow your trees in close forest, and no matter what height they attain or how soon they attain it, the annual rings will be close together, and the timber will be slow grown. It is a mere question of forest management. Trees in open order will produce branches and coarse timber, with wide annual rings; trees grown in close canopy will yield clean planks with narrow annual rings. Here are some examples from a wood of Mr. Elwes's, at Colesborne, in Gloucestershire. Most of these trees measure 125 feet in height, and compare favorably in cleanness of bole with the following examples from Savoy—silver fir with a few spruce, and silver fir, with a larch or two.

It is idle to say that timber cannot be grown at a handsome profit in Great Britain, but it is equally idle to attempt to grow it at a profit unless sound principles of commercial forestry are adopted.

I now come to the other branch of my subject—the condition of woodland on private estates in this country. In dealing with that, I must be understood to generalise. I could name certain estates on which the principles of sound forestry are in full practice, and of which the proceeds of the woods contribute a considerable part of the revenue. But taking one estate with another, I shall not be accused of exaggeration if I describe the woods as run upon amateur lines, more or less modified by local custom. It is not the custom to expect a land agent to have had any training in economic forestry; still less likely is it that the owner himself shall have had such training. It would be natural, then, that neither the agent nor his employer should attempt to interfere with the management of the woods. But what landowner is there so poor in spirit that he does not aspire to direct in person the operations in his woods? He has a forester or woodman, no doubt, with an efficient staff under him, but that forester is very seldom remunerated on a scale calculated to secure sound technical knowledge. On some estates he combines the duties of forester with that of head gardener; on others he receives a salary equal to that of a head gamekeeper. He is at best but a foreman woodman, and even if he pursues sound routine operations these are constantly liable to be interrupted or diverted at the caprice of his employer. It would be strange, indeed, if the result of such a want of system proved anything but disastrous. Imagine any man investing liberal capital in a large farm, without any technical knowledge of farming, or the rotation of crops, and yet dictating to his farm bailiff how and where those crops were to be grown. The result would be apparent in a very few seasons, and, so far as that farm was concerned, the balance-sheet would spell bankruptcy. Even in that case, the amateur farmer would have the example of sound agriculture as practised by his neighbour, and he would have the sense to pick up some knowledge as he went along. But where is the amateur forester to turn for guidance in this country? Perhaps there is not within his county a single example of close canopy and clean timber. And further, whereas the effect of bad farming is manifest in two or three seasons, mistakes in forestry do not become apparent for two or three generations.

I stood not long ago beside the owner of one of the noblest parks in England. He had brought me to see an oak wood, originally pure forest, about 50 acres in extent, which was causing him much concern. They were splendid trees, about 180 or 200 years old, averaging 100 feet in height with 40, 50, 60 feet of glorious clean boles. I don't know

the like of this wood, as it must have been, if it be not the forest of Cour Chevernay on the Loire opposite Blois. Twenty years ago there cannot have been less than 9,000 or 10,000 cubic feet per acre, which, taken at only 1s. a foot, represents a value on the 50 acres of some £25,000, or £500 an acre. Who could have blamed the owner had he treated this woodland as a crop? Well, all his neighbours would have blamed him bitterly, so deeply rooted has become our habit of looking upon woodland merely as an extra—a luxury—a playground. And yet I maintain that it was folly not to turn this timber to account. For

FIG. 3.

LARCH, BEECH, AND SPRUCE AT COLESBORNE, GLOUCESTERSHIRE.

look you what has happened. My friend had all the amateur love of trees which is so characteristic of English country gentlemen. About twenty years ago, thinking to improve the landscape, he had glades cut in this noble grove, and thinned out the whole of it severely. His forester, if he knew his business, may have warned him what must happen if pure oak high wood is suddenly converted into trees in open order. If he did so, his advice was disregarded; the owner knew what he wanted, but the result has been far different. Nearly every tree has become stagheaded and thrown out an eruption of growth all along the

FIG. 4.

LARCH, BEECH, AND SPRUCE AT COLESBORNE, GLOUCESTERSHIRE.

stems and branches. The grove has been ruined.

My friend did me the honour to ask my opinion. If I had given it, he would have called me a beggarly Scot, so I held my peace, even from good words. But I had no doubt what a wise forester's advice would be—fell all the remaining trees and replant. As near as I could judge, there seemed to be an average of thirty oaks left on every acre. These cannot be worth less than £7 10s. apiece standing, or an aggregate of £11,300 on the 50 acres. I have purpose'y put this calculation very low, for I was shown where one of these oaks had been felled recently, and the timber sold for £20. But I know what will happen. My friend loves his trees; he will never harden his heart to part with them; they will go from bad to worse, and the greater part of this money will be sacrificed. The future of these noble trees will be like that of the mournful ruins in Cadzow Forest, Lanarkshire.

Now one must take things as one finds them, even if one may entertain a hope that better understanding may prevail some day. The British landowner has a perfect right to manage his woods in the way best calculated to secure the objects he has in view. These objects, I think, are generally as follows :—

1st. Landscape effect, especially park scenery.

2nd. Game cover.

3rd. Shelter.

4th. Timber for estate purposes.

To insist upon the uniform application of strict continental sytem to all classes of land in this country is very far from what I advocate. In the first place, I don't think close canopy is as essential on a great part of our area as it is on dry soils and climate. The climate and soil of our islands, part of them, at least, is far more propitious to tree growth than those of a great deal of the forest area of Europe. But what I do advocate is the application of strict system, modified to suit our peculiar circumstances.

Now let us take these four objects which I have mentioned as uppermost in the average landowner's purpose, and see how far they are to be reconciled with a sound system of forestry.

1. *Landscape effect, especially park scenery.* He must be callous indeed, be he landowner or simple wayfarer, who is indifferent to the charm of English park scenery, which consists of prairie with groves and scattered trees. But it is an effect which can only be obtained as the result of age. The finest park scenery is a gradual evolution from close forest, and never can be attained by planting single trees apart upon a plain. By that means, you obtain nothing but huge cabbages with an ugly horizontal browzing line, or picturesque monstrosities such as the great beech at Kilkerran, Ayrshire, which girths 19 ft. 6 in. at 5 ft. high, or malformed specimens like this ash. Now compare with such results some park effects that have been evolved out of high forest.

Trees are social creatures; for the development of their true character they require the discipline of close company to rear stately stems and preserve symmetrical heads. I must not linger over long upon this fascinating subject, but if anyone doubts my contention that good forestry is not only reconcileable with the finest park scenery, but is actually essential to its production, let him visit Ashridge-park, within 30 miles of this room, and reflect upon the process which reared the famous beeches there.

It is out of a well-grown woodland only that you can carve a beautiful park. For the last 60 or 70 years most of us have been doing our best to render growing woods incapable of producing fine park scenery. We have been taught to thin mercilessly—to allow no tree to interfere with another, thereby preventing the development of clean stems, and encouraging instead a wild profusion of branches, as if the object had been to produce an orchard.

Well, but it is argued, a regular forest, grown on Continental principles, is painfully monotonous. You will lose all the variety and life of an English park if you insist upon close canopy. My answer is that of all rural industries forestry, in its ordinary operations, is productive of the most picturesque scenes.

There is another and more pressing aspect of park management. British landowners are far less affluent they were thirty, fifty, and one hundred years ago. It is a question with many of them whether they can maintain their parks at all. Is it not sheer blindness to refuse to develop what may be rendered not only a source of regular income but a reserve to be drawn upon in times of special pressure, such as the payment of death duties. Why, so far from destroying English park scenery, the application of science and system to wood management may be the very means of saving many a park from the hammer or the speculative builder.

Before it can be hoped that landowners will

take that course, they must apply themselves vigorously to acquire the principles of the craft, unlearn a great deal that they have been taught, and harden their hearts to deal with their woods in general as a crop.

2. *Game Cover*.—This is perhaps the point at which British landowners and foresters are most directly at issue, and I admit that it is not easy to reconcile the idea of an English game cover with economic forestry, seeing that underwood has ceased to have any commercial value. At the same time it is a fact that our present system of battue came from Germany, where forests are managed on the strictest principles of commerce. Close high wood is disliked by game, chiefly because of the scarcity of food there; but cover shooting is such an artificial affair now that pheasants may be made to haunt whatever ground is best adapted for their artistic destruction. It is merely a question of where their food is provided. As for cover, there is no cover better than young wood up to 15 or 20 years, and in a woodland, managed on economic principles, there will always be a due proportion of young wood, into which birds may be driven for the rise.

But there is one form of game absolutely incompatible, not only with profitable, but with decent forestry. Will any landowner, honestly and boldly, calculate what ground game, especially rabbits, cost him per acre of plantation. Every yard of ground that is planted must be wire netted, and this cannot be done at less than 6d. a yard. Where the woodland is worked in proper annual rotation, ten acres, say, filled every year, and ten acres replanted, the cost of wire netting is at a minimum, for a square of ten acres may be fenced for between £20 and £30—say an additional cost of 50s. an acre. A pretty heavy inroad upon capital expenditure; but you must multiply this indefinitely if you wish to deal with blocks of less than ten acres—if you wish, for instance,

FIG. 5.

DENNY ENCLOSURE, NEW FOREST, SHOWING NATURAL REGENERATION INSIDE FENCE.

to plant up blanks in woodland from half an acre to two or three acres in extent. And even this is not all. Where the detestable rabbit abounds, ground cleared of timber cannot be restored by natural regeneration. In such a case, there must be placed to the debit of the rabbit account, not only 50s. an acre, the cost of wire netting, but £6 an acre, the cost of replanting which would be unnecessary on ground suitable for natural regeneration. In other words, the presence of rabbits means an initial tax upon young forest of £8 10s. an acre, which may be equal to half the fee of the land. If British forestry is ever to regain the place to which our soil, climate and requirements entitle it, it must be relieved from the intolerable scourge of rabbits. The place for the rabbit, and the only place, is the warren. In those scenes I showed on the screen from Ashridge-park, you may have noticed how bare was the ground, not only under, but around the beech trees. To show what that ground is capable of doing in the way of natural regeneration, look at this part of it which has been protected from rabbits and deer for the last 15 or 20 years.

3. *Shelter.*—Shelter from sea blasts or from the prevailing wind is a most legitimate object in forming a plantation. I have only a few words to say about it. Do not grudge a few acres in laying out belts. Even a narrow strip affords warmth and shelter so long as it is young, but there are few things more cheerless than the same strip when the trees are approaching maturity, and the wind blows draughtily through it. The most successful sea shelter which I have seen is on Lord Leicester's estate at Holkham, where miles of sand dunes have been planted with four different species of conifer, Scots pine, pinaster, Austrian and Corsican; and the Corsican has beaten all the others in a very remarkable manner. It even reproduces itself, although there is much ground game about.

4. *Timber for Estate Purposes.*—A most important object this, and one that is usually accomplished, but at what cost! I do not hesitate to say that on many estates if the rent of the ground, annual rates, cost of planting and wage bill be reckoned, much money would be saved if not a foot of home wood were used, and foreign supplies bought from the timber merchant. And yet you say that timber ought to be grown for the market at a profit! Certainly it ought, but not on the present system, not unless timber is treated as a crop with a regular fall and grown of good quality. It is the cut-and-come-again method that is ruinous both in cost and in quality. The annual fall ought to supply both estate purposes and the timber market. Yet I have heard within the last few months landowners complaining that they cannot get an offer even for fine timber. No, because they have not secured a proper business connection. To do that two things are necessary, as any greengrocer will tell you, regularity of supply and uniformity of quality. It is estimated that there are 3,000,000 acres of woodland of sorts in Great Britain and Ireland. In Belgium there are only 1,750,000 acres yielding a return of £4,000,000 a year. At that rate British woodlands ought to yield £70,000,000 a year. At what figure would the most liberal estimate fix the return? Yet British timber properly grown would be no whit inferior to Belgian.

The fact is there is no regular trade in home timber. Merchants cannot rely upon a steady home supply so they have recourse to countries where they can be sure of getting exactly the quantity and quality they require. Mr. Nisbet has put the case concisely.

"Available markets cannot be utilised to the best advantage if the quantity of wood offered one year is large, the next small, a third year wanting altogether, and so on irregularly. 'First a hunger, then a burst,' is bad in this as in all other cases." Add to this, that woodland subject to inordinate thinning—to arboriculture instead of forestry—produce timber of such inferior quality as to lead architects to stipulate for foreign timber in all their work.

Now I think I have said enough to explain the general character of what is on my mind in this matter. To go closer into details would outrun reasonable limits of time. I am convinced that by adopting sounder principles and continuity of treatment, both the State and private owners of land might indefinitely enrich future generations, and indemnify themselves meanwhile, wholly or in part, for the outlay and lock-up of capital by clearing the ground of a great deal of ill-grown wood which occupies it just now.

One circumstance is highly favourable to reform. There is plenty of sound instruction in sylviculture to be had. Five and twenty years ago British landowners could only turn to such vicious and misleading instructors as Brown and Michie. Now there is abundance of good literature, and such writers as Schlich, Nisbet, and Forbes are at hand to pilot enquirers into the true course.

DISCUSSION.

The SECRETARY read the following letter from Dr. Schlich:—

It is a great disappointment to me that I am unable to hear Sir Herbert Maxwell read his important paper on "British Woodlands," this evening, but as you have been good enough to send me an advanced copy, you will, I trust, allow me to offer a few remarks on it. Until now most British landowners have hesitated to admit that economic sylviculture can be applied to their woodlands, maintaining that the latter are a thing apart, and now Sir Herbert Maxwell comes forward to denounce publicly his former opinions, and to urge the application of rational sylviculture, and above all systematic and sustained treatment, in the case not only of our ordinary woodlands, but even in that of parks and other ornamental woods. By doing this, Sir Herbert Maxwell has rendered a greater service to the development of rational forestry in this country than he is probably himself aware. But he has done even more than that, inasmuch as he calls upon the Government to devote the exceedingly modest sum of £10,000 a year to the acquisition and afforestation of waste lands, thus creating object-lessons which cannot fail to have the most beneficial effect upon the further extension of our woodlands. He tells us that hundreds of thousands of acres of mountain land fit for planting can be acquired at the rate of £2 10s. an acre, representing 25 years purchase of the present rent derived from sheep grazing, and he calculates that a return of considerably more than 5 per cent. on the invested capital can be secured. Let us hope that those in power will read what Sir Herbert Maxwell says and act accordingly! Great efforts are now being made in Britain, to provide theoretical instruction in forestry, at quite a number of educational establishments. This pleases many people who take an interest in the matter, but it is only part of the business. All this theoretical instruction will, as it were, be of comparatively small value unless we provide at the same time the means of practical instruction. For this purpose we require systematically-managed woodlands, which are found few and far between in these islands. The Commissioners of Woods have of late years made a gallant effort to manage the Crown forests on rational lines and according to well-arranged plans; but what we require over and above this is that the State (or, in some cases, corporations) should acquire areas of mountain and heath lands in various parts of the country, plant them up, and manage them rationally, so that they may serve as examples to the surrounding private proprietors and to the student of forestry. Even if, as Sir Herbert Maxwell suggests, only £10,000 a year were appropriated for the purpose, some substantial good could be done in England, Wales, and Scotland. As to Ireland, the splendid opportunity which the administration of the latest Irish Land Act offers of acquiring and planting surplus areas in the case of estates which are broken up for sale to the tenants, should certainly not be missed. I hear sad accounts from Ireland as to the great destruction of the remaining woodlands by the new proprietors, and it seems to me to be the direct duty of the State to make good, at any rate, the mischief which the Land Act is working in this respect. The woodlands belonging to the State, or the Crown, whether already existing, or to be planted, should serve another very important object, namely, the collection of correct statistics, showing the yield, the receipts and expenses connected with woodlands, managed on economic lines. At the present time, there are hardly any areas in this country which could serve for the above purpose As long as we have no tables giving the probable increment and yield of our woodlands, we are groping in the dark as to the financial results of the forest industry. To sum up, I must once more thank Sir Herbert Maxwell for the great service which he has rendered to-day to a cause in the interests of which I have struggled against adverse conditions during the last twenty years.

The CHAIRMAN thought that those who had given attention to sylviculture would be the first to admit that the opinions expressed by the author were, as might have been expected, perfectly orthodox. He did not think one could have had a more admirable precept as to the opportunities and duties of private landowners and the State, whose duty was a very considerable one, than that given in the paper. The author had referred to the question of instruction in sylviculture. There were no doubt better books ready to hand in the present day than their fathers had, but at the same time the study of sylviculture was very largely a matter of object-lessons. English people were very empirical in their habits, and foresters were especially so. Without viewing the woods, the museums, the collections, and all the different object-lessons which were so perfectly established in other civilised States, he was not very hopeful of any large departure in the private or public management of woodlands. The author had referred to the shortcomings of the Report of the Departmental Committee. He admitted that the recommendations of the Report were not adequate to the requirements of the country, but he thought the recommendations went as far as they were likely to get any Government to go, and as far as they were justified in asking any Government to go, because one was not justified in undertaking any great creation of sylviculture in this country without having men properly trained to undertake it. Apart from a few Indian Forest officers and others whom one could count almost upon the fingers of one hand, there were none who were competent of expressing an opinion as to how sylviculture should be conducted in Britain. Indeed, without the object-lessons, he doubted whether the best of the experts could

say what ought to be done. Some of the best foresters in Germany and France had very truly pointed out that there was probably no country in the world where some of the most valuable American coniferæ could be better grown than in parts of Britain, but they were not yet grown upon sylvicultural principles. English people had barely begun to plant them properly, and it must be some time before it was possible to judge how far those anticipations would be fulfilled. He believed the first requirement which had to be met, was the adequate provision, by experimental areas and forest schools, for the training of men competent to manage woodlands. The author's proposal of setting aside £10,000 a year was, he thought, a very moderate one. It was undoubtedly necessary, by some grant of that kind, to make provision for giving sylviculture, either by the State or by the individual owner, a fair chance. The author had divided modern forestry into three parts,—ornamental forestry, economic sylviculture for profit, and objects such as the amelioration of climate, the prevention of erosion, or the storage of water, which could be attained by plantations under certain conditions. He believed England had no rivals in the world in regard to ornamental afforesting, such as pinetums, parks, and pleasure grounds, but sylviculture was practically unknown except in very limited areas; and the ornamental forests themselves were limited, because, yielding no profit, the areas under timber were necessarily limited by the resources of the owner. England could not do better than maintain the advantage she possessed in ornamental plantations, and could not too soon make provision for enabling landowners to have profitable sylviculture, to store water, to prevent erosion, and obtain the other advantages which were incidental to proper sylvicultural treatment of the land. England imported nearly thirty million pounds worth of timber a year, twenty-five of which could be profitably grown at home; and it was about time some system was adopted, which had a fair chance of success, of giving foresters adequate training to enable them to deal intelligently with the work that lay before them.

Sir DIETRICH BRANDIS, K.C.I.E., said the great truth that trees in order to yield valuable timber must grow in thick masses where they drew each other up to the greatest height an individual tree could attain, and where, at the same time, their close contact prevented the formation of branches, which was the chief thing to teach those who managed woodlands in this country, had been admirably stated by the author. Another point which had been equally well set forth was that certain trees required a mixture with other trees in order to thrive. If the oak trees in the Forest of Dean had been grown in company either with beech or silver fir, they would have presented quite a different appearance from their present miserable state. In 1865, on his first furlough home from India, with the enthusiasm of a young man, he visited a great many of the woodlands in England and Scotland, including some of the finest coppice woods of ash and sweet chesnut which he had ever seen in his life. The owner told him that he had used the best wheat land, and raised very strong seedlings, managed the land under a rotation of seven years, and produced hop-poles which were in large demand in those days, the land thus yielding him £5 an acre net. It was very difficult not only in England but in other countries to obtain the financial results of the forest management of private estates, and that was one of the chief reasons why States and private individuals did not take the question up. The communal forests in Germany were the staple of the wealth of the country, and the Crown forests of this country might be made extremely valuable as object-lessons of rational forestry if they were properly managed. The plan which the author had foreshadowed would do an immense deal towards making people familiar with the idea that the planting up of waste lands was profitable. The timber merchants in Saxony, Bavaria, and other parts of Germany were able to make their plans in advance because they knew every year that each forest range was expected to yield a certain quantity of timber of a certain kind, while in England there was no regular yield which enabled the timber merchant to frame his plans, and consequently he found it more convenient to make arrangements for buying the timber at the port where it arrived from abroad. It was interesting in connection with rabbits, to state that in Richmond-park young oaks were now coming up under the oaks which were standing very far apart. This would have been impossible when millions of rabbits were allowed there.

Mr. H. J. ELWES said that no doubt the principles which the author had so well laid down were very sound, but there was another point of view which he did not think he had sufficiently touched upon, namely, the feeling amongst almost all landowners who were able to live upon their estates that not only from an ornamental but a family point of view, a man who tried to manage his trees properly was looked upon as a wretch who was doing the worst he possibly could for his estate. A great many landowners did not realise the enormous sums they lost annually in interest through allowing timber to stand long after it was mature; but at the same time, if they could afford to do so, it seemed to him that not only the landowners but their relations and the country generally derived from the old English system of treating trees an amount of pleasure that could hardly be over-rated. People did not realise the enormous indebtedness they were under to the owners of those trees for allowing them to stand long after they ought to have been cut down, and the feeling was so strong that he did not believe any amount of teaching would alter it. He thought English sylviculturists were under a debt to German foresters for

having emphasised in a more pointed way than had been done by English writers the essential fact that without some nurse, of which beech was by far the best, fine big timber could not be grown on poor land. He was not one of those who admitted that waste land could be planted with profit. In a great many districts half of the expenditure thus involved would be a dead loss. Local knowledge and experience in such matters were of even more importance than teaching. There was no mistake so great as to imagine that a person after having learned the principles of forestry, could apply them in any part of England without local knowledge and observation, and experienced foresters had made extraordinary mistakes by giving advice in districts where they did not know the whole of the conditions. If a man had a desire to plant his waste land, he firmly believed that in many cases it would be a better investment to plant it from an ornamental and sporting point of view than from a timber point of view; because he had seen gigantic failures not only in State forests, but in private woods through planting trees on land where they would not grow except to a scrubby imperfect state. In looking through the evidence given before the Commission on Agriculture in 1886, in which long lists of accounts in connection with woodlands were given, he did not find one single argument which would justify a man in saying that planting waste land was really a good investment at the present time; and although he had himself for many years past been planting very largely, he had come to the conclusion that it was very much in the nature of a gambling transaction. Nevertheless, woods and plantations were a source of continual pleasure, which grew with age, and therefore planting was a thing to be encouraged by every possible means. But before advising the State or private landowners to embark very largely in what must be, to a great extent, a rather uncertain future, one ought to emphasise the importance first of all of getting some reasonable reduction in the taxation on growing timber; secondly, of getting some reasonable protection to English investors for the benefit of the country much more than themselves—that they should not have the whole of their profits wiped out by unlimited foreign competition; and, thirdly, by giving such education in forestry as would enable landowners to obtain a forester who was not too fine a gentleman to work with his own hands, and, at the same time, had something more than the mere local knowledge which the average country woodman had.

Professor W. R. FISHER thought the point ought to be mentioned in connection with the management of the Crown forests, that they had never had a fair chance, because, instead of all ages of the trees being represented in them, they were nearly all planted at the same time. The result was, that it was impossible to get a steady revenue from them, as a large sum of money was spent, perhaps, eighty years ago, and the woods were still too young to be felled. The book-keeping was also of a extremely miscellaneous character. Instead of the woods being kept entirely separate from other parts of the accounts, they were mixed up with the game and buildings, and cleaning gravel paths, which made it impossible to show what the woods really did produce. He thought it would be of very great benefit if the Crown forests were put in the hands of one man instead of two. At present there were two Commissioners of Woods and Forests, neither of whom had complete charge of the woods. He believed there were forty square miles of oak forests in the Crown land, and there was not the slightest reason why those woods should not be as good as those in Normandy. As the Crown woodlands were probably the only lands in the country where fine oak was likely to be grown, he thought the Government should take the matter in hand by putting the woods under one authority and having a separate system of accounts, although a statement of the expenditure and revenue was no measure whatever of the excellent work that was being done by Mr. Stafford Howard in the Crown woodlands at the present moment.

Mr. ALEXANDER HOWARD quoted figures which showed the decrease in the size of the timber which had been sent to this country from the Baltic in the last 25 years, and which also went to prove that the sources of supply had entirely changed. It consequently appeared to him that the author's suggestion that there was a great future before home-grown timber was likely to be correct. He thoroughly agreed with the author that there must be a steady and organised system of supply, otherwise it would be quite impossible to make reckonings or to get timber merchants interested in the subject. Another source of difficulty was the taxation of the country, it having been estimated by a friend of his that English people paid £1,000 in rates in England for every £100 that was paid in other countries. The railway rates and other expenses of delivery in this country were also absolutely impossible. Timber could be brought 2,000 miles from the interior of another continent, across an enormous ocean and brought into England for less than English timber could be brought from a town 100 miles from London to London itself. Until railway rates were brought within the compass of the price for which timber could be charged, it was impossible for English landowners to compete with foreigners. The quality of the timber was also most important. More enthusiasm must be displayed by English landowners before British timber would be able to compete with the much cleaner and better grown qualities which were imported from abroad.

On the motion of the CHAIRMAN, a very hearty vote of thanks was accorded to Sir Herbert Maxwell for his interesting paper.

Sir HERBERT MAXWELL, in reply to Mr. Elwes's remark in regard to the inferior quality of some English land, said that however far certain portions of the surface of Great Britain had departed from the forest condition, there was very little doubt that practically the whole of the British Isles were once under forest except the extreme tops of the hills; and in order to restore that forest it was necessary to restore the forest conditions - a very difficult operation. He hoped he had not been understood to throw any reflection upon the administration of His Majesty's Office of Woods. Most people were aware of the great difficulties under which that office laboured, including the perpetual interference of Parliament with the proper administration of such a magnificent estate as the 64,000 acres of the New Forest. He had every sympathy with the administration, and had merely mentioned the balance-sheet in support of his contention that it was in vain under present conditions for any private landowner to look to the State for an example in sound forestry. He had mentioned in the paper the inadequate remuneration of foresters in general. Foresters worked for a wage which did not justify their employer expecting them to display more than mere ordinary knowledge of routine. A landowner with a moderate extent of woodlands could very seldom afford to pay his forester more than the current rate of wages, especially if the loss upon his woodlands was as serious as it usually was. Would it not be possible for landowners in the same county or the same neighbourhood to co-operate and employ one competent man to act as head forester on half a dozen different estates? He thought that suggestion was worthy of consideration, because it was obvious that in order to have proper woodlands it was necessary to have a man of very superior capacity.

COTTON MILLS IN CHINA.

The China Mission of the Blackburn Chamber of Commerce, which visited Shanghai when cotton mills under foreign management were in their infancy, gave it as their opinion that while the new mills could not be considered as directly competing with the productions of the United Kingdom, the surrounding circumstances and conditions were so favourable to the expanson of trade that Lancashire must eventually suffer serious indirect loss. But it cannot be said that as yet cotton mills in China have done much to fulfil this expectation. The spinning of cotton into yarn, and the weaving of yarn into cloth, are industries which have existed in China for a thousand years, but it was not until 1895, when the Treaty of Shimonosaki gave freedom to foreigners to engage in all kinds of manufacturing industries in the open ports of China, and permitted them to import machinery for that purpose, that mills for treating raw cotton by means of steam-driven machinery began to be erected. No less than eleven mills, Chinese and foreign, were then taken in hand, but since then expansion has been unexpectedly slow. In his report just issued (Cd. 2237) Mr. J. W. Jamieson, the British Commercial *Attaché* in China, gives a list of seventeen mills in China and Hong Kong spinning yarn, or weaving cloth by means of team-driven machinery, and none of them seem to be doing well. Four of them represent half a million of European capital sunk. It was assumed that with the aid of cheap labour, skilled management, and abundant supplies of good cotton, a handsome profit would be earned, but one of these companies has had to write down its capital 50 per cent., and dividends are still wanting.

The main feature which has operated against the Chinese mills has been their failure to obtain supplies of raw cotton at reasonable prices and in good condition. It was assumed at the outset that cotton would never go beyond 11·50 taels per picul, as for years its price has remained stationary at 11 taels. But there are rings and combinations in China as elsewhere, and the Chinese middlemen have gradually forced up prices until now cotton has to be bought at 90 per cent. over the figure on which the original calculations were based. The fall in the price of silver has, of course, materially contributed to this rise, there being a difference of 24 per cent. between the figures of 1896 and 1903. The mills have to contend, too, with the practice of adulterating cotton with water. It has been attempted to stamp out this evil with the aid of official support, but just as Chinese officialdom in the past neglected to protect vital commercial interests centering in tea and silk, so now it is unlikely that it will take any efficient steps to protect the cotton industry. Much might be done by extending areas of cultivation, improving the quality of the fibre, giving care to the selection of seeds and the use of fertilisers, and freeing the industry from the incidence of vexatious imports and petty interference, but Chinese officials are not likely to change their time-honoured attitude of regarding industrial development simply as an additional means of extracting revenue. Chinese labour is said to be becoming more efficient year by year, and it is certainly cheap. The working day lasts 13½ hours, night shifts working 10 hours extra. Many mills in Shanghai pay by "piece-work," and the average amount earned is about 6d. a day; but cheap labour is only one of the conditions of success in the cotton manufacturing industry as in others, and a good deal will have to be changed before the mills of Shanghai give a fair return upon the capital invested in them.

RED SEA PEARLS.

The Red Sea pearl fisheries at Lohia is an industry about which very little appears to be be known. The name Lohia applies to a small group of islands at the lower end of the Red Sea, and pearl fishing has been carried on there for a number of years. The divers

are all Arabs, but the men who finance the industry are generally natives of India, and for this reason it is hard to get an idea of the exact output in number of pearls, or their value, for any particular year, as a good number of pearls found at Lohia go direct to Bombay, and are not reported at Aden at all. The trade returns for 1903 show that there were exported from Aden pearls to the value of £15,400, but this, it is said, is by no means the total output of the Lohia pearl fisheries for that year. There are several merchants at Aden who deal in these pearls. Each pearl or collection of pearls is sold according to the particular perfection of the pearl or collection, and there can be no price given for pearls indiscriminately. Several years ago there was a considerable trade with the United States in mother-of-pearl shells from the pearl fisheries, but the entire output now goes to Europe. Pearls are the most popular of all the precious stones among the inhabitants of India and Arabia, and it is very seldom that a native woman of any social position is seen without pearl ornaments of some kind either in rings for the nose, ears, or fingers, and some even wear pearl rings on their toes. Owing to the fact that pearls are so popular as an ornament with these people, and to their almost universal use in and about Aden, the local demand almost entirely absorbs the output of the pearl fisheries in that part of the world, and very sew pearls secured in those districts find their way to European or American markets. In the Persian Gulf there are extensive pearl fisheries, the entire output going to Bombay.

GENERAL NOTES.

Wireless Telegraphy in the Andamans.—Sir Richard Temple, in his paper "Round about the Andamans and Nicobars," read before the Indian Section of the Society in December, 1899, strongly urged the installation of wireless telegraphy at Port Blair, in order to place the Andaman Islands in direct communication with India. In a recent number of *Nature* the fulfilment of Sir Richard's desire is announced. The experiments, according to the *Pioneer Mail*, give most satisfactory results. A recent message transmitted from Port Blair reached Calcutta in nineteen minutes, though it had come over the land-lines after being received at Diamond Island.

Agricultural Education and Forestry Exhibition, 1905.—A forestry department will be organised in connection with the forthcoming show of the Royal Agricultural Society of England, to be held at Park Royal from the 27th to 30th June next. The exhibition will follow generally upon the lines of that of last year, and the co-operation of owners of forests and woodlands, their foresters, and others interested, are invited to assist by sending suitable exhibits to illustrate the various branches of British forestry. Copies of an entry form, with detailed conditions, can be obtained on application to the Secretary, Royal Agricultural Society of England, 13, Hanover-square, W.

German Trade in Morocco.—In view of the visit of the German Emperor to Tangier, and what is being said in Germany about the commercial interests of Germany in Morocco, it may be interesting to note the figures of German trade in Morocco as given in the latest official returns. Cheap freights on German lines, and cheap handling at the German ports of discharge, are gradually improving the German position, but Germany is still fourth on the list, both as to exports and imports. In 1903, Great Britain had 34½ per cent. of the export trade of Tangier, Germany only 2¼; Great Britain 47 per cent. of the import trade, Germany only 4½. The value of the export trade to the United Kingdom was £132,706; to France, £49,968; to Germany, £8,000. Of the import trade the figures stood respectively for the three countries at £206,246, £120,098, and £37,345. So with Laraich. The export trade with the United Kingdom was valued at £28,667, with France at £13,926, with Germany at only £2,597. It was the same with the imports. From the United Kingdom they were valued at £388,713; from France at £257,068; from Germany at only £22,234. With Tetuan, Germany seems to have ceased doing business. In shipping, the German position is better, the German tonnage entering Tangier being exceeded only by the British and Spanish; at Laraich it is exceeded only by the British and French. Assuming some improvement in German trade with Morocco since these returns were made up, they suffice to show that German trade with Morocco is not of great importance.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

April 5.—"Ancient Architecture of the Great Zimbabwe." By Richard N. Hall.

April 12.—"The Industrial Resources of the State of Matto Grosso, Brazil." By George Torrance Milne, F.R.G.S. Colonel George Earl Church will preside.

Indian Section.

Thursday afternoons, at 4.30 o'clock:—

April 6.—"The Prospects of the Shan States." By Sir J. George Scott, K.C.I.E. ("Shway Yoe"), Superintendent and Political Officer, Southern Shan States. The Most Hon. the Marquis of Bath, will preside.

Colonial Section.

Tuesday afternoons at 4.30 o'clock:—

May 23.—"The Cape to Cairo Railway." By Sir Charles H. T. Metcalfe, Bart., M.Inst.C.E.

APPLIED ART SECTION.

Tuesdays, at 4.30 or 8 o'clock:—

MAY 2, 4.30 p.m.—"The Monumental Treatment of Bronze." By J. STARKIE GARDNER. SIR GEORGE BIRDWOOD, K.C.I.E., C.S I., will preside. This meeting has unavoidably been postponed from April 11, as previously announced.

MAY 16, 4.30 p.m.—"Popular Jewelry." By MONSIEUR RENE LALIQUE (Paris). ARTHUR LASENBY LIBERTY, J.P., will preside.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

HERBERT LAWS WEBB, "Telephony." Four Lectures.

LECTURE IV.—APRIL 3.—*Development and Tariffs.*—Supremacy of telephonic communication—Essential features of modern telephone service—Organisation of telephone plant and business—Evolution of telephone rates—Scientific telephone tariff—Effect of area on cost—Varying demands of consumers—Graded classes of service—Telephone development in different countries—Long distance service and rates.

ALAN S. COLE, C.B., "Some Aspects of Ancient and Modern Embroidery." Two Lectures. May 1, 8.

HENRY WILLOCK RAVENSHAW, Assoc. M.Inst.C.E., Mem.Fed.Inst.Min.Eng., "The Uses of Electricity in Mines." Two Lectures. May 15, 22.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, APRIL 3... SOCIETY OF ARTS, John-street, Adelphi, W C., 8 p.m. (Cantor Lecture.) Mr. Herbert Laws Webb, "Telephony." (Lecture IV.)

Farmers' Club, Whitehall-court, S.W., 4 p.m. Rev H. H. Slater, "Wild Birds."

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Engineers, in the Theatre of the United Service Institution, Whitehall, S.W., 7½ p.m. Mr. W. Pollard Digby, "Statistics of British and American Rolling Stock."

Chemical Industry (London Section), Burlington-house, W., 8 p.m. 1. Messrs. C. Napier Hake and R. J. Lewis, "The Formation of Sulphuric Esters in the Nitration of Cellulose and thei influence on stability." 2. Mr. H. W. Brownsdon, "The proof of Percussion Caps."

British Architects, 9, Conduit-street, W., 8 p.m. Prof. Beresford Pite and Mr. J. W. Simpson' "The Planning of Cities and Public Places."

Camera Club, Charing-cross-road, W.C , 8½ p.m.

Victoria Institute, 8, Adelphi-terrace, W.C., 4½ p.m. Dr. J. M. Peebles, "Essay on Immortality."

TUESDAY, APRIL 4...Royal Institution, Albemarle-street, W., 5 p.m. Mr. Perceval Landon, "Tibet." (Lecture I.)

Central Chamber of Agriculture (at the HOUSE OF THE SOCIETY OF ARTS), 11 a.m.

Alpine Club, 23, Savile-row, W., 8½ p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on paper by Mr. C. S. R. Palmer. "Coolgardie Water Supply."

Pathological, 20, Hanover-square, W., 8½ p.m

Faraday Society, 92, Victoria-street, S.W., 8 p m, 1. Mr. A. H. Hiorns, "Alloys of Copper and Antimony and Copper and Bismuth" (illustrated). 2. Mr. E. Kilburn Scott, "Refractory Materials for Furnace Linings" (Discussion). 3. Messrs. S. Hutton and W. H. Patterson, 'Electrically Heated Carbon Tube Furnaces" (Part I.)

WEDNESDAY, APRIL 5...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Richard N. Hall, "Ancient Architecture of the Great Zimbabwe."

Geological, Burlington-house, W., 8 p.m.

Royal Archæological Institution, 20, Hanover-square, W., 4 p.m. Paper on "Somerset Church Towers: their characteristics and classification."

Obstetrical, 20, Hanover-square, W., 8 p.m.

THURSDAY, APRIL 6. .SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p m. (Indian Section.) Sir J. George Scott, K.C.I.E. ("Shway Yoe"), "The Prospects of the Shan States."

Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Prof. R. J. Harvey Gibson, "Intraaxillary Scales of Aquatic Monocdyledons." 2. Mrs. Veley, "A Further Communication on the Study of *Pelomyxa palustris.*"

Chemical, Burlington-house, W., 8 p.m. Papers will be read by Mr. McIntosh, Mr. R. N. V. Sidgwick, Mr. A. Slator, Mr. C. E. Fawsitt, Messrs. A. E. Dixon and J. Hawthorne, Mr. J. Y. Buchanan, Mr. S. Ruhemann, Mr. M. O. Forster and Miss H. M. Judd, Mr. H. A. D. Jowett, Mr. J. T. Nance, Messrs. H. Jackson and D. N. Laurie, Mr. F. S. Kipping, and Messrs. F. S. Kipping and A. E. Hunter.

United Service Institution, Whitehall, S.W., 3 p.m. Mr. Douglas Owen, "Maritime Warfare: Modern Conditiens and the Ancient 'Prize Laws.'"

Royal Institution, Albemarle-street, W., 5 p.m. Prof. R. Meldola, "Synthetic Chemistry" (Experimental). (Lecture I.)

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on (1) "The Report on the International Congress at St. Louis," by Mr. W. Duddell. 2. The Papers on "Systems of Electric Units," by Prof. Ascoli, Prof. G. Giorgi, Professors H. S. Carhart and G. W. Patterson, and Dr. F. A. Wolff.

Camera Club, Charing-cross-road, W.C., 8½ p.m.

FRIDAY, APRIL 7...Royal Institution, Albemarle-street, W., 9 p.m. Mr. Alfred Moreley, "American Industry."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) 1. Mr. R. G. Clark, "Cofferdams for Dock Use." 2. Mr. J. R. Fox, "Bath Corporation Waterworks Extension."

Architectural Association, 18, Tufton-street, S.W., 7½ p.m. Lecture by Mr. H. Phillips Fletcher.

Geologists' Association, University College, W.C., 8 p.m.

Junior Institution of Engineers, Westminster Palace Hotel, S.W., 8 p.m. Mr. George H. Hughes, "Practical Notes on Water Works Construction."

Philological, University College, W.C., 8 p.m.

Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m.

SATURDAY, APRIL 8...Royal Institution, Albemarle-street, W., 3 p.m. Lord Rayleigh, "Some Controverted Questions Optics." (Lecture II.)

Journal of the Society of Arts.

No. 2,733. VOL. LIII.

FRIDAY, APRIL 7, 1905.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, APRIL 12, 8 p.m. (Ordinary Meeting.) GEORGE TORRANCE MILNE, "The Industrial Resources of the State of Matto Grosso, Brazil."

The meeting of the Applied Art Section, previously announced for Tuesday, April 11th, has been postponed to May 2nd, when Mr. J. STARKIE GARDNER will read a paper on "The Monumental Treatment of Bronze."

CANTOR LECTURES.

Mr. H. L. WEBB delivered on Monday evening, 3rd inst., the fourth and last lecture of his Course on "Telephony."

A vote of thanks to the lecturer for his valuable course of lectures was passed, on the motion of the Chairman.

The lectures will be published in the *Journal* during the summer recess.

INDIAN SECTION.

Thursday afternoon, April 6th; THE MOST HON. THE MARQUIS OF BATH in the chair.

The paper read was "The Prospects of the Shan States," by SIR GEORGE SCOTT, K.C.I.E.

The paper and report of the discussion will be published in a future number of the *Journal*.

COVERS FOR JOURNAL.

For the convenience of members wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1s. 6d. each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

Thursday afternoon, March 16th; SIR GEORGE BIRDWOOD, K.C.I.E., C.S.I., in the chair.

The CHAIRMAN, in opening the meeting, said it would add to the pleasure of those present if he left it to Mr. Hodson to introduce himself to his audience by the delivery of his paper. He had had the privilege of reading it beforehand, and he could confidently say that they would soon find that Mr. Hodson was complete master of his subject. And he was more than that. There were many passages in his paper that would probe them to the quick, all expressed with the literary reticence that proves a man the master also of himself. Born of London and bred of London,—he was a Bluecoat Boy, and is now Registrar of the East London Technical College [Peoples' Palace],—Mr. Hodson's paper is, in a word, racy of the super-subtle sensibility and insight which distinguishes all Londoners worthy of their grave and enviable citizenship. He would only add that he had received a letter from Dr. George Grierson, the eminent philologist, and Director of the Linguistic Survey of India, expressing his deep regret at not being able to attend Mr. Hodson's lecture as he had earnestly hoped to do.

The paper read was—

MANIPUR AND ITS TRIBES.

By T. C. HODSON.

The State of Manipur contains within the area of eight thousand square miles a remarkable congeries of tribes, all of which belong to the family of peoples to which the name Tibeto-Burman has been given. The heart of the little State is the rich and smiling valley, which holds two-thirds of the population and all the civilisation of the country. This is the broad land of the Meitheis, or to use the better known title, the Manipuris. The

population of the hills is a little over one lakh, spread over an area of seven thousand square miles, and falls into two main divisions, Nagas and Kukis.

Surrounded by mighty ranges of mountains, the valley of Manipur has yet attracted the attentions of conquering races, first the Shans, who in the beginning of the fourteenth century poured down into Assam from the confines of Yunnan, and then of the Burmese whose ravages, committed in the early years of the nineteenth century, wrought the utter ruin, military and industrial, of their ancient enemies. The wave of Hindu revivalism which marks the commencement of the eighteenth century extended to Manipur, where it secured the official adoption of Hinduism as the religion of the Rulers of the country.

During the period of British administration the Manipuri settlements in British India have received many recruits, some voluntary, many more or less against their wishes. In places like Nadia, Mathura, Brindaban, Hazaribagh, Dacca, Silchar, there are Manipuri residents and I am sorry to say, that in Cachar and Sylhet they do not possess the best of reputations. In Burma there are small colonies of Manipuris which owe their origin to the Burmese invasions, notably that of 1819, when over 30,000 people, artificers, craftsmen, and cavalrymen of the Kase Horse, were carried away into captivity.

Manipuris.

They belong to the Tibeto-Burman group of the Indo-Chinese race and have the well-known features of that division of the world's inhabitants. Beards and moustaches are rare, so rare that the fortunate possessor of any sort of hirsute decoration receives a special nickname. Of their origin nothing is known beyond legend, which is in their case peculiarly unreliable. Among all the hill tribes are current legends which give them and the Manipuris a common descent. Although I may seem to be anticipating somewhat, yet I think it satisfactorily settled that the tribes of the hills of the province of Assam are all members of one family. I hold this opinion to be based not only on the evidence of the recent linguistic researches, but on an undeniable identity of social structure and early religious system, and on the acknowledgment in the ancient chronicles of Manipur of the universality among them in former days of customs and practices which they have had to abandon since they adopted the formality of Hinduism and which to this day flourish among the hill people.

Dress.

I have referred to the ancient chronicles of Manipur. They are documents of great interest and afford us glimpses into more than the drum and trumpet history of the times. Here and there are mentions of the introduction of some elaborate sumptuary law, of some measure of internal organisation or reform, even of the details of the domestic life of the people. One result of the introduction of sumptuary laws seems to be great monotony, and the costume of the ordinary villager is certainly neither elaborate nor very picturesque. But every holiday affords an excuse for the display of a little finery, and those who are engaged in any sport or pastime naturally find it necessary to have a costume specially set aside for that particular sport. Thus we have the handsome boating costume worn by the steersmen of the boats which annually compete, or the peculiar costume appropriate for the wrestling matches, the most notable feature of it being the spiral headdress, which resembles that worn by the Raja on his coronation, or the horn into which the Marring Naga twists his hair. The men do not have a monopoly of fine feathers, and if the ordinary attire of the women is simple, it is also very dainty, for the stripes of the long petticoat which reaches from the arms down to the ankles are always tastefully matched. Indeed, the Manipuris are very particular to see that the Mohammedan women or Naga women do not wear colours reserved for them and fasten the garment under the left breast, while the latter have to wear it on the right. They have excellent taste in employing flowers as personal ornaments, and their jewellery is all of gold, filigree designs or simple beads being preferred. They and the women of the hill tribes add to the length of their tresses tails of false hair, which are bought in the great bazaar of Imphal. Before marriage custom demands that the girls should have their hair combed over the forehead with two locks at the side, while the dignity of the estate of matrimony is signalised by tying the hair in a knot at the back and combing it away from the forehead. The women in Manipur manage all the retail trade, and the gathering and breaking up of the great bazaar is a sight well worth seeing. The women stream in from all directions carrying their baskets on their heads and sit in rows in appointed places. The most difficult cases which I have had to try

were those arising out of bazaar quarrels. Every girl learns to dance, and the modest and handsome costume they wear sets off their slender figures admirably.

Houses, &c.

A Manipuri village is a long straggling collection of houses, each as far as possible with a separate frontage on the river. Imphal, however, the capital, is less fortunate in the matter of water supply, as the two rivers which pass through it do not suffice for the needs of the population, which is over 30,000. There are some pucca buildings in Imphal, but none, not even excepting the fort and kangla or coronation hall, are of any great antiquity. The Raja used to possess a ceremonial residence, made (not as has been stated in the Naga manner, but) in the style usual before the introduction of Hinduism, and this was called the "sang kai pun-si-ba" or the long-lived hut and granary. The houses are all thatched, though of recent years there has been a boom in galvanised iron sheets for roofing. The temples (public and private) are all of the trabeated style, and some of the teak beams used in the construction of the "natch ghar" are of great length and thickness. The Manipuris are fond of cheap lamps, and developed an annoying habit of stealing the oil lamps used for the illumination of the broad streets of Imphal. To thwart this we introduced acetylene lamps of a simple pattern, but the first night one was stolen. Retribution was swift, for the gentleman who stole it, opened it incautiously, and the gas which had been generated, caught fire and burnt his house down.

Industries, &c.

Of their domestic life little need be said. In the capital there are always attractions, and the daily gathering at the bazaar gives to life that relief without which it would be intolerably dull. In the villages there is a constant round of hard work, for the women take their part in the cultivation and look after the cattle, and spin the cotton and weave the cloths for the use of their lords and masters and for the family. In the valley, with its numerous lakes and jheels, fishing is a valuable industry. The women throw square nets with great skill, and the weirs and fish-traps are ingenious. A very curious method of fishing is practised by the Loi fishers who reside on the borders of the Logtak lake. They drive long bamboo stakes round the floating islands and moor them to the bed of the lake. They then surround the islands with nets and gradually lift the stakes and make fine catches. Many, if not most, of the industries of the country are in the hands of the Loi villagers who represent the original inhabitants of the country. They are ironsmelters, silk weavers, fishermen, potters, refiners of salt, limeburners, and manufacturers of sel, the small bell-metal coin of the country. The Manipuris are excellent cloth weavers and carpenters, and some of the gold and silver work is of fine quality. I have seen an ivory mat, on which the Raja used to sit in durbar, which is composed of fine strands of ivory, plaited into a strong texture, with threads of gold wire here and there through it. Caste prejudices seem to prevent them from turning their undoubted ingenuity to competition with the Lois. This is the reason why the schemes for the development of sericulture in Manipur have hitherto failed. The staple industry is agriculture, the chief crop being rice, which is grown in the fashion common in Eastern Bengal. So fertile is the soil, that in a bumper year the harvest is so plentiful that the price of rice falls to a mere song. In course of time the surplus will be exported to the tea gardens of Assam, along the cart road *via* Kohima. The Mohammedans, who have a "Kazi" of their own, and enjoy a fair tolerance, cultivate opium, which, I think, they sell in Burma, but the amount they produce is not large.

Games.

The Manipuris are fond of games, at which they are expert. Every boy learns to play hockey before he has attained to the dignity of clothes, and then those who can afford a pony learn the polo game, which I venture to regard as the gift of Manipur to us. The breed of ponies has sadly deteriorated of late years, but the skill of the Manipuris is unabated. The rules of the game require no more than seven a side, and a goal is scored whenever the ball crosses the back line. They are particularly expert at strokes on the near side, and I attribute their proficiency at a stroke which is full of difficulties to most European players, to the fact that, in order to protect their legs from blows at hockey, they always keep their sticks across guarding the leg, thus developing the muscles of the forearm much more than would be the case if they used the off side stroke to the same extent. The pastime of rambai hunba or dart-throwing is dying out, but it is a relic of the days when the Kase Horse were the most formidable arm of the Burmese

forces. The dart is a peacock feather with an iron point of some weight. Down the middle of this is a rod with a looped thong by which it is grasped. They whirl it in the air and at the psychological moment let it go. The missile travels 80 to a 100 yards with fair accuracy, and can be very easily discharged in retreat. Of the wrestling not much can be said except that the appropriate dress is very quaint. The foot races are also very keenly contested. But the palm for general interest must be awarded to the boat races. The Pannahs (or four revenue divisions of the country) each send in a crew, and by old custom the steersman of the defeated boat becomes the slave of the steersman of the winning boat, a custom which interfered with my plans for the promotion of sport among the military police, for the native officers of the battalion thought that it would be necessary for them to pay the usual fine of fifty rupees on each occasion of a race between the companies. The games take place during the Durga pujahs, and the Naga subjects of the State come down to Imphal in numbers to perform their characteristic war and other dances, a special day being set apart for them. There are sword players, and the event which draws the greatest crowd is the party of mimics whose performance is not always very decent. The great indoor game is kang, played with the round seed of the creeper, and it is identical with the game of konyon described by Captain Lewin. I shall later on have a word to say of the ballads of the country, but their recitation is a constant source of pleasure to the village folk, who listen to the token of love lorn couples, and the adventures of Ching Thang Khomba in his flights from the Burmese invaders with delight and interest. The way in which these ballads are recited by men ignorant of writing is to me an interesting proof of the manner in which the Homeric poetry was preserved in Greece before the introduction of writing. The language of the ballads differs about as much from modern Manipuri as the language of the Iliad from the Greek of Plato.

Divisions.

The Meitheis are divided into seven tribes, each of which has a chief, who is known as the "king" (Ningthou) of the tribe. The Raja is the chief of the Ningthouja or Royal clan. These clans are exogamous, though there are also one or two exceptions involving special disabilities on the marriages of members of certain subdivisions of the clans. There are reasons for holding that there were formerly ten clans. Two have disappeared, and one has been amalgamated with one of the present seven. The Brahmins are of foreign descent, and comprise fifty-one yumnaks. They come from various parts of India, such as Guzerat, Krishnagar, Allahabad, Santipur, Khanpur, Mathura, Assam, Orissa, Radha Kund, and Rai Bareli. Their ancestors are said to have come to Manipur, some at as early a date as the middle of the fifteenth century. The Lois, of whom there are not many separate villages left, are reputed to be the descendants of the early inhabitants of the valley, who were dispossessed by the Meitheis. The consolidation of the Meithei hegemony did not take place till the beginning of the fourteenth century, while the separateness of the Moirangs, still one of the most numerous and best localised clans, was preserved till our own days. The Mohammedans are said to be the descendants of captives taken in the raids which the Manipuris made in the heyday of their power on Cachar.

Internal Organisation.

Every Meithei belongs, in theory at least, to three social groups, the kei-rup or tiger club, formed to provide means for destroying the tigers and leopards which infested the valley; the sing-lup or wood club, which provides the wood for the cremation of its members and acts as a benefit society in helping its members; and, finally, the lal-lup or war club or militia. During the period of foreign aggression, when the Manipuris made war on Cachar and Burma and enjoyed a very independent position, the lal-lup was used for its proper purpose, but in the piping times of peace it was found expedient by the rulers of the country to employ the organisation on works of public utility, a policy with which little fault can be found. However, the people were soon put to work for the benefit of the Raja, and the system became one of organised oppression, which stifled the industry of the country. The internal administration of Manipur exhibits traces of Shan influence, and is remarkably complete. Each village possesses a number of officers each responsible for some duty connected with the Government of the locality, and though there is a tendency to assert that these offices are hereditary, I am confident that they went by favour in earlier days. But, corrupt as the methods of the Rajas may seem to us, their nominees have

been found to be very capable men. The relative precedence of all these functionaries has been carefully worked out, and when we introduced a chaukidari or village police, we had some difficulty in finding out the right position these humble officers were to receive at village festivals. The native courts were three in number, excluding the special court which took cognisance of offences committed by Brahmins. The Paja dealt with matrimonial suits and the Chirap with ordinary civil and criminal work, while military cases came before the Topgard. We have added a series of courts of first instance which deal with minor cases, while civil and criminal and appellate authority has been conferred on a new Chirap. The Paja has been abolished, its jurisdiction being merged in that of the Panchayets, while the political agent and his assistant have extensive powers of exercising control over the proceedings of the native courts from which they are courts of appeal. But in remote villages the people still have recourse to the simpler methods of ordeal and oath, though not to the same extent as is the case among the hill people. The bulk of the crime comes from the capital. There is very little crime against the person. Cattle theft is common, and there is, or ought to be, in the jail at the present time a man who had the reputation of being able to carry a calf through the bazaar without being detected. He modestly disclaimed this power. The jail I knew was not a prison, for no self-respecting prisoner need have stayed there a moment longer than he liked, as the walls could be climbed at any point; but I knew of only one jail-breaker whose exploits gained for him the nickname of Flyaway. I have heard Colonel Maxwell grimly assert that in times of famine he had to put the guard inside the jail to keep the people from breaking in. The village headmen acted as police in former times, but we have now established a civil and a military police force, which keeps us in close touch with the village officers whose authority has been maintained.

Marriage Customs.

The tribes composing the Meithei are, as has been said, exogamous, and the ceremony of marriage consists of the formal exchange of presents and cohabitation. Morality is lax and divorce is easy. In fact, the position of women in regard to marriage is that of slavery, and the price of adultery is that of a full slave in former times, viz., 50 rupees. Polygamy is practised especially by the members of the Royal family, the Raja being allowed four principal wives, and any number not exceeding 108 of wives of less dignity. In polygamous households custom regulates the attentions to be paid to the several wives in order of their seniority.

Inheritance.

The system of inheritance is, in general, devolution of the property to the youngest son, because the elders have, or are supposed to have, received provision during their fathers lifetime. Women have only a right to maintenance.

Tenure of Land.

All land is, in theory, the property of the Raja, but this theory has been disturbed by the rules introduced by us during the administration of the State, which provide for annual leases which are renewable unless in very special circumstances. Revenue used to be paid in kind, and the demand which was formally about one per cent. of the produce of the field, was raised by the time the tax was collected, to about twelve times the right amount. In order to secure payment of the indemnity and tribute, a money payment has been required, and the sudden change has undoubtedly worked some hardship, because there was a scarcity of coined money, and the only people who could command supplies of coined money were the foreign merchants in the bazaar, who have made handsome profits out of the situation. They keep the rates of exchange between grain and coin low or high, as it suits them, making a double profit on each transaction. I have known rice so low that it did not pay to employ labour on husking it. At the present time there is a grave need for determining the village rights which have grown up, over waste lands and grazing lands. I have known speculative investors who took out leases for waste lands and then charged the villages so much per head of cattle grazed thereon. One advantage of the annual pottah system was that it enabled us to deal equitably with such cases. A survey and settlement would be good for the people, though it would meet with strenuous opposition from the Manipuri authorities, who hope that the accession of the Raja will be the signal for the return of the old order of things with themselves on top.

Religion, &c.

I am sorry that I cannot emulate the easy brevity of Father Sangermano, who declares that the "people of Cassay worship the basil and other herbs after the manner of the ancient Egyptians." We have in Manipur an excellent example of the superposition of a stratum of Hinduism over the bedrock of an animistic religion. Formally, the religion of the State or the dominant tribe in the State is Hinduism which was brought into the country at an early date. The records of the Brahmin families warrants the belief that some of their ancestors reached Manipur at as distant a date as the middle of the fifteenth century, while the official adoption of Hinduism took place at the beginning of the eighteenth century. The recent census gave the Lois communities an opportunity of improving their social position as they were asked to state their religion, and promptly gave themselves the name of Hindus —much to the disgust of the orthodox. The addition of converts is still going on, for not only do whole villages drop the peculiar customs which mark them out as members of a pre-Hindu system, but individuals are constantly becoming "Hindus." Nevertheless the old religion flourishes, even prospers, side by side with Hinduism. The tribal head is the tribal priest, and annually performs certain rites of worship of the deified ancestor of the tribe, who, by a curious process of amalgamation, is popularly identified with some Deity of natural forces. Every householder is entitled to worship the "imang lai" or household deity on such occasions as births, marriages, and deaths, although he may be at the same time inviting the village Brahmin to come in and assist. By a natural induction the priest is also the doctor, for it is characteristic of animistic religions that all untoward or mysterious events are the manifestation of supernatural or spiritual power, and while prevention is recognised as better than cure, still a cure can only be effected by expelling the evil spirit which is causing the sickness, and therefore recourse is had to the "maibas" or spirit specialists. The "maiba" of the Manipur of to-day possesses some knowledge of herbs and drugs and uses massage freely in his treatment of ailments, but his association with divine mysteries is undoubted. They also believe in omens, dreams, and witchcraft. The most malevolent class of evil spirits are the "hing-cha-bis" or female ghosts, who eat live people. If a woman dies in child-birth, the calamity is attributed to a "hing-cha-bi," and the poor infant whose birth has been the occasion of such sorrow, is by some regarded as the "hing-cha-bi"—a belief which explains the custom found among many hill tribes of burying such children, alive or dead it mattered not, in the same grave as its dead mother.

Tabus.

Every Meithei tribe is associated with some object, in one case a reed, in another a buffalo, in a third a fish, which is not to be touched by the members of that tribe. The direst penalties, so terrible that they are beyond the reach of human imagination, await the impious wretch who wittingly or by accident breaks this prohibition, which is only one of many which have for their object the preservation of the clan from impurity. Special circumstances may cause temporary or limited tabu: thus when a man falls from a tree and is killed, the piba or head of the clan declares that tree to be tabu to the clan for ever. The purificatory ceremonies which precede the rites of the native worship in Manipur, whether the occasion be one of regular occurrence, such as the annual loosing of the scapegoat at the foot of the sacred hill Khabru, or are of an extraordinary and unusual nature such as the ceremonies for procuring rainfall, find their closest parallel in the remarkable tabus which invest the personality of the heads of the clans of a Naga village. The word "namungba" exactly corresponds to the Naga words "neina," "genna." Deeply seated is the belief in omens, and the annual loosing of the scapegoat is intended to secure good luck for the people during the coming year. Now Khabru is a very sacred hill, and the grassy plain at its foot is Kaithenmanbi or the gathering place of the ghosts. Again Khabru is the Deity peculiar to the Luang clan, and when there is snow to be seen on the summit of this, the highest mountain in Manipur, the popular and poetical phrase is that the God has spread his cloth, "Lai-phi tare."

Omens, &c.

Not the least important part of the coronation of the Raja was the determination by the assembled soothsayers, astrologers, and wiseacres of all sorts of the luck of the coming reign, which they declared was indicated firstly, by the length of time the Raja was able to sit on a pipe in an inner chamber, beneath which dwelt a fiery dragon, and then by careful observation of the stones on which the royal feet trod, in their

passage from the Kangla or coronation hall to the fortified enclosure of the Palace. On special occasions the Raja, the head of the State and therefore the chief priest, was able by the following ceremony to divest himself of his sins and to transfer them to some unhappy criminal who gained his liberty by receiving them. A scaffolding was erected, and on the top the Raja bathed himself while the receiver of the royal guilt sat below and received the sins and the splashings of the water. The Raja completed the transference of his sins by handing over his old clothes to the man below, who wore them and then went free. It was said that as long as the nong-sha or the animals of the Sun God, stone erections in front of the Kangla, stood safe and sound, so long would the good luck of the country and its independence continue. They survived the Burmese wars only to be destroyed in 1891 for reasons of high policy. Every year the luck of the State as well as the issue of the year was determined by the appointment of a name-giver Chahitaba. The Maibas nominate a man whose horoscope is in favourable relations with the general signs. He then worships the Raja addressing him as the incarnation of Pakangba, the divine ancestor of the royal clan, and undertakes to bear all the misfortunes of the country and the sins of the Raja till the end of the year, when custom demands that all Manipuris should wear new clothes and throw away all their old cooking pots. At the end of a prosperous year the namegiver is rewarded, and I once heard a deputation urge on the Political Agent in all seriousness the proposal that he should fine or imprison the chahitaba or name-giver of the year whose unrighteousness was clearly demonstrated by the epidemic of cholera which had decimated the State.

And the Brahmin flourishes in this atmosphere. I do not doubt that the elaborate system of tabu rules which has left such remarkable customs behind it, enabled the early missionaries of Hinduism to argue that only a very little was needed to make the people of Manipur very good Hindus. The Maiba is left in peace and the celebrations of the nature worship never interfere with the worship of the Hindu Deities. The system of caste is based on tabu rules, and we shall see in the hills of Manipur an embryonic caste system maintained by the declaration that the particular industry which is associated with it is tabu to members of other communities, who are so far susceptible to regard for such a prohibition that they disregard their own interests and forbid their people to practise the art of cloth weaving.

Ballads.

Superstitions abound, for to the extravagance and fancies of animism are added the signs, wonders, omens, and portents in which the Hindu places full and implicit belief. The ballad mongers of the country recite the woes of Dhanan jai, the saint and mystic, alternately with the tale of Numit kappa, or the man who shot the sun. The virtues of asceticism and charity to Brahmins are the theme of the one, while the other is probably a genuine native production, and for that reason of greater interest. In it they tell how in early days there were two suns, the one of which rose as his brother set. The slaves murmured at this addition to their burden, and one, bolder than the rest, fashioned unto himself a bow and arrow, wherewith he practised until his aim became perfect. Then he lay in wait, and, carefully aiming, struck the Sun God from his horse as he was about to begin his career through the heavens. The Sun God, wounded, fled in terror, and his brother with him. For ten long days the Sun Gods lay hidden, averting their faces from the sons of men who had done this outrage upon them. For ten long days the land lay in darkness, and no man worked, and the crops perished, and the cattle died, and the plight of the land was sorry indeed. Then the king took counsel of his wise men, and made prayers to the gods, who helped them not. Then the ten kings of the country and the ten gods of the country turned to the wise goddess who knew the interpretation of dreams, and besought her to plead with the Sun God, but he would not relent for her entreaties. Then they went to the Princess Panthoibi, for she had knowledge of many mysteries, and she showed them the magical ceremonies which would induce the wounded deity to take pity on the land. These things they did as she showed them, and at last the Sun God relented and came back, but his brother, the wounded deity, never returned to the abode of wicked men.

Hill Tribes.

The hill tribes are divided into two main groups, Nagas and Kukis. In general, it may be said that the Nagas live in permanent villages with no definite village chief in secular matters, while the Kukis are disposed to move their villages periodically, and own

obedience to a chief. There are, however, subdivisions which form links between these groups although they are linguistically distinct. There are Kuki villages which we know have occupied their present sites for several centuries, there are Naga villages which keep to the village site while practising a rotation of cultivation, and if the authority of the headman of a Naga khel is almost entirely sacerdotal, extending only to secular affairs by stress of personal ability, the exclusion of a Kuki Raja from sacerdotal authority is limited by a custom which demands his presence on occasions when his people are specially tabu, occasions which equally involve a Naga clan in tabu, a fact which goes far to prove, or as the cautious Oxford don put it, to render it extremely probable that there was once a time when the head of a tribe or clan, Naga and Kuki, was invested with authority in sacred as well as in secular matters, and that their divergent development is due to accidents of history which we may guess at but with which we are very imperfectly acquainted. While I adhere to the general classification I preserve a profound belief in the ultimate homogeneity of these people in spite of the differences of coiffure, dress, speech, houses, and methods of agriculture.

We have in Manipur the following Naga tribes:—Mao, Maram, Tangkhul, Marring, Kabui, and others such as the Quoirengs, Khoiraos and Liyangs. The Mao and Maram tribes inhabit the hills bordering on the Naga Hills District on the extreme north of the State, while the Tangkhuls, a large and enterprising tribe, occupy the hills to the east and north-east of the valley. The Kabuis hold the hills on the west and north-west of the valley, and the Marrings are found in the hills south-east of the valley. The Quoirengs, Khoiraos, and Liyangs are found in the hills north and north-west of the valley. The Kukis are found in small settlements dispersed all over the State and comprise the old Kukis in the south and a number of dependent tribes such as the Waipès, Dvites, &c., all of whom are settled in the south of the State.

Classification.

The labours of the Linguistic Survey of India enable us to classify these tribes according to their linguistic affinities. The Mao, the Maram, the Tangkhul, and the Marring Nagas are placed by Dr. Grierson in a sub-group to which he gives the name Naga Kuki, indicating thereby that their languages approximate to both standards, the Mao and the Maram dialects being more allied, as their geographical propinquity would lead one to expect, to the true Naga languages, while the Tangkhul and Marring dialects present features of considerable similarity to the Kuki Chin languages. It is, therefore, possible to consider them as links between the two groups, the true Nagas on the north and the Kukis and Chins on the south. The languages spoken by the Kabuis and the Khoiraos belong to another sub-group, the Naga Bodo, and are thus to be regarded as a link between the Naga languages and the Bodo dialects such as Mech, Garo and Bodo. Dr. Grierson also points out that there are many points which indicate a connection with the Kuki languages in both the Kabui and the Khoirao dialects. It is natural that Kuki influence should be predominant in Manipur as the Meithei language is a member, the most important member, linguistically as well as politically, of the Kuki Chin group of languages, and it is certain that as the rule of Manipur was extended over these tribes the language of Manipur, the *lingua franca* of a large part of this area, followed it. The Manipuris never learnt the languages of their subjects but imposed upon them the necessity of learning Meithei. It occurs to me that it would be a matter of great philological interest if some scholar on the spot were to collect the songs sung by the Nagas and Kukis on their high days and holidays as these are in a language which is so archaic as to be unintelligible at the present day to the members of the tribe. The same is true in Manipur, but I have some specimens of the ballads of Manipur in the early dialect, with a version in the modern language, which show the lines on which the development of the language has taken place.

Origin.

Among all the tribes in the Manipur State is current a legend which connects them with the Kukis and the Manipuris. The legend is constant in declaring that the Kukis are descended from the eldest of three brothers; that they are the children of the second, while the Manipuris are the progeny of the youngest. Some support this story by pointing to the fact that the Manipuris have the best share in the valley, while the Kukis are kept to the barren hills, where only by jhuming can they subsist. Others find it buttressed by a tale that one day the three brothers were playing in the village, and started a jumping competition. The

eldest, the ancestor of the Kukis, cleared the jump; the father of all the Nagas just failed to get over it, and got his hands and feet muddy; while the Manipuri fell right into the mire; and so from that day to this the Kukis do not wash at all, the Nagas wash only their feet and hands, and the Manipuris bathe regularly.

There are other legends, especially among the Tangkhuls, which declare them to have sprung from the valley which they left because the heat and the mosquitoes made life unendurable. In another case they say their ancestor came from a village Maikel, which is by another tradition the place of the origin of the ancestor of all the hill folk. The Dvités, who are living in a state of servitude to Kukis, say that once upon a time two eggs were found in a paddy basket belonging to Aisan, King of the Thados. One was cooked, but from the other, which hatched out in the warmth of the sun, there sprang a beautiful lad, who became the ancestor of the tribe.

Appearance, &c.

In appearance all these tribes are distinctly non-Aryan, though I have seen men, especially among the Tangkhuls, who have a well-cut profile. One seldom sees a Naga or Kuki with hair on his face. It is easy to distinguish them by their different styles of dress, and by the peculiar manner in which they cut their hair, for one of the points which distinguishes a Naga from a Kuki is that the Naga cuts his hair, while the Kuki does not cut it, but ties it up behind. The Tangkhul fashion is to cut the hair closely at the sides, leaving a broad band in the middle, which is parted and tied in a tail at the back. The Mao and Maram Nagas either cut it at the sides—but not to the same height as the Tangkhuls—or they allow it to grow in thick masses of curls, which, unlike the Manipuris, they think an embellishment to beauty. The Kabuis adopt the Mao fashion, which resembles that of the true Angamis, their immediate neighbours on the north. The Marrings do not cut their hair, and, while the Kuki coils his hair at the back, the Marring twists his into a curious spiral horn in front, through which he thrusts a steel bodkin, which is put to a number of various uses, almost as many as a lady's hairpin. They say that this bodkin is a relic of the time when they knew how to read and write, and the steel bodkin was the implement in vogue; but the dogs greedily ate up the skins while the men were bathing, and from that day to this the useful art of writing has been lost to them. But it is interesting to note how the fashions are even now susceptible to modification, for I have met Tangkhuls who wore their hair dressed in the Marring fashion, and others who would pass as Kukis by tying their hair back when long enough. Throughout the hills we find that the girls have their hair either cut short and only allowed to grow just before marriage, or, if worn long before marriage, then combed back and knotted at the back, like the Manipuri unmarried girls. Here, again, it is reasonably certain that if one meets a girl with her hair cut short, she comes from a Naga village, while the Kuki maidens keep their hair long. The Tangkhul and the Marring Nagas have no certain and general fashion, as in some villages the girls have the hair cut, in others long and uncut.

But the cloths worn by the several tribes afford as good a means as any other of distinguishing them, because they adhere most strictly to the colours which custom has prescribed as peculiar to their tribe. Thus the Tangkhuls wear blankets of red and blue stripes, the Maos and Marams keep to cloths of a pattern similar to those worn by the Angamis, white in the centre with red and blue stripes round the edge. The Kabuis wear a plainer cloth, the centre being blue with white and red edges. The women also have their distinctive colours. Those of the Tangkhuls, especially in the great weaving villages, are handsome and varied, and the colours they use are blue, white and red. Among the Liyangs I noticed women wearing petticoats with yellow or kharki coloured bands with black stripes about two inches wide in between. The Maos and the Marams are kilt wearers, and in some cases the men of Liyang and Khoirao villages wear either the kilt or the waistcloth with the fringed pendant ends which is worn both by the Kabui and the Tangkul. On the gala days when a dance is to be performed the men assume an unusual amount of finery. Nothing is more remarkable or picturesque than the peculiar attire of a Mao or Maram warrior. His head-piece is a wicker helmet with a brass or bell metal plate in front and a chin strap of wood covered with red berries and green beetles wings and round ear pieces decorated the same style, while from the lower edge of helmet hang tresses of hair, in older times the signs of successful raids. A great warrior may wear a decoration of goats' hair dyed red and yellow and black, which betokens valour in the field, and he girds on a tail, a piece of

wood projecting about three feet with tails of goats' hair dyed red and black hanging from it. But this also serves a useful purpose as there is a receptacle in it for panjis or sharpened bamboo spikes with which to impede the onset of an enemy. His leggings are of finely plaited cane work in red and yellow bands. Instead of a helmet some wear a strange head dress like a pair of horns in light cane and ornamented with red and yellow bands. The hair is tied up at the back in a tight knot fastened down by a coil of cotton wool which is also used to decorate the lobes of the ears. The weapons are an oval shield of wicker work covered with the skin of a bear or with black cloth having a red band down the middle, a spear about nine feet long, which for show purposes is ornamented with red and black goats' hair and the universal dao. Some of them have guns which are produced on such occasions as village festivals. The Maos and Marams wear the ivory ring over the arm and a shell round the neck, while the Tangkhuls prefer a brass necklace with hairtails and brass rings. But there are special cloths for the chiefs, and the fate of the rash man who would dare to wear a chieftain's robe is not capable of precise definition, as there is no case of the sort on record. These cloths are generally ornamented with fringed ends and a handsome border of yellow, red, white, and green pointed decoration. The more expensive cloths have the sign manual of the weaver woven in the hem generally as a lozenge-shaped ornamentation in coloured threads. Kukis wear a dhoti and a pagri, and their women wear petticoats of a dark blue ground with woven patterns of light blue.

ORNAMENTS.

I have incidentally referred to some of the ornaments worn by the men. They and the women wear necklaces of polished cornelian beads by which great store is set. Among one tribe, the Tangkhuls, and then only in the most distant and least wealthy villages, is tattooing practised. They told me that it was done to enable them to identify their wives in the world hereafter, and that it was introduced among them by the Chom Ningthou, a mysterious personage who seems to be connected with the Shan States beyond.

AGRICULTURE.

The Nagas practice both the irrigation system of agriculture and the method which is known in these hills as jhuming. The water channels are of great length, and the ingenuity with which these savage engineers overcome obstacles is always a marvel to me. I have seen water brought four miles and the source would be only a few hundred feet above the fields. The rules regulating the distribution and enjoyment of the water are very complicated, but have as their end the fair and equable supply to all the fields in turn. The jhum system*, which is practised by Kukis, even when, as is the case with the old Kuki villages, they have permanent village sites, is wasteful in the extreme, and is only practised where the slope of the hills and the nature of the soil make permanent fields impossible. The Mao Nagas surround their villages with rows of polled trees, and their cultivation is in general the finest in the hills. The staple is rice, but they grow winter crops. The Kabuis practise a regular rotation, but annually go through a solemn ceremony of taking the omens to determine the direction in which the cultivation for the next year is to be. Their villages are permanent though they change the area of their cultivation from year to year and subsist, almost entirely, by jhuming.

HOUSES, &c.

The houses of the Naga tribes approximate to one type. They are built with sloping ridges, high in front and low at the back. In general the houses are thatched with grass, but the Tangkhuls use pine planks. The floor of the house is the earth well trodden down, and the furniture is not extensive, a few baskets, a dhan pounder or two, and the hewn logs on which the rice is pounded. The villages are irregular, and in former times were surrounded by a stockade, but the policy of Manipur has been throughout one of steady disarmament. Built on the top of ridges of branches of the main ranges, they are well elevated, and though water is at some distance, they occupy formidable military positions. In every village are small platforms on which the village gossips sit and smoke their pipes. The interior of a Naga house is only one degree less filthy than the lane outside. The most conspicuous house in any village is as a rule the bachelors' club, wherein they sleep and live in strict discipline. Great social merit accrues to the public-spirited individual who gives up his house to the bachelors.

Kuki houses are generally raised from the

* "Journal Society of Arts," Vol. xliii. (1895), page 178.

ground with an open verandah in floor. Each house is surrounded by a stockade, and a fence protects the whole village, the centre of which is the chief's house. As a rule the Kukis build their villages in secluded spots in the jungle, and have in a few instances established their abode alongside a Naga village, much to the disgust of their neighbours.

INDUSTRIES.

Nearly all the Naga and Kuki tribes make their own cloths at home, but in the case of the Tangkhuls, six villages, all in close proximity to one another, specialise in the manufacture of cloths and are rapidly forming a caste of cloth weavers, for they do their utmost to prevent their girls marrying into other villages, and I know a woman who married a man of a foreign village, and when she attempted to weave cloths in her new home, the villagers stopped her saying that it was not allowed to them to make cloths, and that misfortune would come to them if she introduced this new industry. The Tanghuls present us with other cases of specialised and localised industries, viz., salt making and pottery. They do not use the wheel, but mould the pots round a bamboo cylinder and curve it into the required shape by hand, adding geometrical patterns at a later stage. This industry is only practised in the neighbourhood of outcrops of suitable clay. The salt wells are found in the extreme north-east of the State, and are generally in close proximity to the beds of rivers. The brine is evaporated in shallow iron korais, which are hired from the State for a small annual sum.

HUNTING.

The Nagas are fond of hunting in large parties, and have elaborate rules as to the disposition and sharing of the quarry, and any neglect of these rules leads to serious trouble. Some Naga tribes use a poison to stupefy the fish, while the Tangkhuls drive the fish into the shallows or use seine nets. Kukis, however, hunt singly and track their game. They have the art of making a crude sort of gunpowder, and their traps, pitfalls, and snares are most ingenious.

SPORTS.

The sports of the Nagas and Kukis are simple, consisting of weight-throwing, weight-lifting, jumping and dancing, and in all the villages one may see an eager group watching the progress of a game of draughts between two champions. They also play the game of kang with the seed of a creeper, and they have an elaborate game very similar to the game of fox and geese. I have seen small boys with whip tops. The girls sometimes join in a game of kang, but marriage brings them so many cares and duties, that they have little time for games, having to fill their spare time by smoking their pipes as hard as they can to get the juice for their husbands who sip this nauseous liquor when on a journey, and consider it extremely palatable and sustaining. In a Kuki village I saw some small boys walking on a pair of stilts. The Naga dances are interesting, but the Kukis have in general the reputation of being the better musicians. The Tangkhul Nagas are expert buglers, and the Kukis have a musical instrument, consisting of a gourd into which are inserted first a pipe through which the wind is blown, and then seven pipes each fitted with a vibrating reed, for the production of the tones.

ORGANISATION.

It is not easy to define a tribe with reference to Nagas, as they themselves do not recognise any tribal unity; they have no tribal head, and apparently no tribal deity. So far as my enquiries go, they tend to show that linguistic unity is recognised by the Nagas as one of the constituents of a tribe, and that each tribe has a tribal tabu. I obtain the first element from their marriage laws, which forbid the marriage of people of different tribes, and I find that in practice this means people with different dialects. The second element is much more obscure, but in two cases, the Marams and the Tangkhuls, there is a general tabu object—in the former the pig, and in the latter the goat—which may not be eaten by any members of the tribe. The Maram story about the manner in which the pig came to be forbidden to them shows clearly enough that it is a true totem, and that they hold themselves to be considered to be the descendants of a porcine ancestor. The Tangkhuls say that goats are very human and like children, and that any man who eats goats' flesh will go mad and die, and they do not keep goats in consequence. The common unit recognised by the Nagas is the village, which is a collection of clans each feigning descent from a common ancestor, and living in close propinquity, with common food prohibitions, and worshipping all together at the same time. These elements—community of descent, commensality, propinquity, and a

common family worship, are strongly marked, and affect the whole of their social and religious life. Marriage is strictly forbidden between members of the same clan, and as strictly forbidden outside the tribe. All rules of inheritance are based on the principle of male agnatic succession, and default of male heirs is hardly possible, because it cannot occur unless the whole clan is extinct. Women on marriage cease to be members of the clan in which they have been brought up, and, while they have a right to a share of the moveable property of the family, they cannot under any circumstances take land away from the tribe. Land is held in severalty, and may be disposed of by sale or gift, but not to an outsider. The Tangkhuls have a curious custom of inheritance which renders it necessary for the father of the family to move out when his son marries, and the same rule applies to the succession to village offices. In order to defeat our revenue law, by which the villages are taxed according to the number of houses in the village, this custom is being abandoned, and smaller huts in immediate contiguity to the former house are constructed. The Kabuis have a custom—which is not peculiar to them, as it is also found among the Kukis in their neighbourhood—of paying the "price of the bones" of a wife to her parents or nearest male relative on her death. The fixed rate is one cow. In certain circumstances the payment is remitted, viz., when a woman dies in childbirth, or is killed by an enemy or by some wild beast, or dies of cholera, or when she dies away from her husband's house.

Marriage Rules.

Among Kukis and Nagas marriage is a matter of price, and while some tribes allow the *Times* system of a deposit, others insist on full payment before the bride is brought to her husband. There are many marriages of inclination, as may be expected in a state of society where the women are not secluded, and where custom permits a considerable degree of licence before marriage, while insisting on the strictest fidelity after marriage. There are certain points about the marriage price which need some consideration. The price varies very considerably, and its variations are due to many causes, as for instance among the Maos and Marams, fierce fighting folk, whose numbers have been thinned by internecine feuds, the price of a bride is low because men are scarce, and it is strictly fixed by custom. Among the Tangkhuls a woman from the northern tribes used to fetch a higher price than a southern woman because the men of the north were more ready and more able to avenge illtreatment than the men of the south, an example of the way in which exogamism tends to put an end to feuds. The Kukis, a people with a strict monarchical system, pay more for their brides if they are the daughters of Rajas than for the mere commoner. Then among the Anals, a small village of Kuki origin, we have the system of payment by service, the son-in-law actually serving as a servant in the house of his father-in-law for three years. Is payment by service earlier than payment by exchange or cash, and is the curious custom of mandu (or payment for the wife's bones) in any way connected with the price of the bride? Divorce is not easy and is expensive. Polygamy is allowed but is rare.

Oaths and Ordeals.

The village authorities deal with many village disputes, and the employment of the oath or the ordeal is general. Some of the oaths are very quaint. The Kabuis take a handful of rice, some ashes, and some salt and dust. They mix the rice with the ashes and declare that they will find all their rice spoilt as this rice is if they lie. Then they mix the salt with the dust, and say, "May our salt turn to dust if we lie." There are oaths on the spear or dao, or on the tiger's tooth. The Mao Nagas are very particular in employing different oaths in the different kinds of quarrel. In a case about land the oath is to be taken on the earth, while if the dispute is about a wood or jungle, the oath on the axe may be employed. When the case is between two villages or two clans of one village, then the oath on the body of a cat is used. Similarly among the Tangkhuls one can get an increasing range of liability by making the persons swear on the village instead of the clan, and a common ordeal among them is to give the verdict against the village which first loses a life, be it of a child in arms. The water ordeal is use in the following manner. Each village produces a champion who grasps a stone at the bottom of a pool, and at the word, dives below and holds on as long as possible, and the verdict is given to the village whose representative holds himself down longest. After all, these are crude ways of appealing to providence to decide a matter which is incapable of solution by human ingenuity.

Religion.

The religion of the hill tribes is animistic, but they all have a definite scheme of deities presided over by a chief, the Creator who is now inaccessible to the prayers of man. Below the regular ranks of the deities are the spirits, some of whom are the ghosts of human beings, especially of those whose manner of death indicates divine displeasure, and to propitiate them is the business of the wise men who are called in to diagnose the cause of sicknesses, *i.e.*, to say what spirit is causing the poor fellow to be ill, and the sacrifice which will appease or drive the evil visitor out. There are two sets of beliefs about earthquakes. The one current among the Tangkhuls and the Kabuis is to the effect that earthquakes are caused by a deity who resides underneath the earth, and who is disturbed by the fear that all men have perished, and when he shakes the earth, they all cry out, "We are alive." The other belief is that the earth and the sky are the female and the male principle respectively, and that earthquakes are due to their embrace.

Genna.

The foundation of their worship is the system of "genna," which in many respects corresponds to the tabu system of the Polynesian peoples. I have found it convenient to deal with it by a somewhat careful analysis into "gennas" affecting first the whole community, then to deal with those which only concern classes of individuals or sections of the community, and then those which involve individuals. In the next place, there are "gennas" which are of regular occurrence, and some which are occasioned by events of an unusual nature. Finally, there is the mechanism by which the "gennas" obtain validity.

The "gennas" which affect the whole community are the public festivals for the crops, which vary in number from some twelve to three, and are occasioned by the stages of the cultivating season; and the annual festival at which the spirits of those who have died within the year are laid to rest by the participation of the whole village in funeral rites. It is a common feature of these village "gennas" that at their commencement the gates of the village are closed against all comers until the end of the ceremony. Now, if there is any unusual or extraordinary occurrence, such as the death of a woman in childbirth, the destruction of the village by fire, the advent of an epidemic sickness, or an earthquake, or an eclipse, the whole village is "genna" for that day. At some of the crop "gennas," especially those which celebrate the beginning of the cultivating season, the men and women eat and cook apart. During the whole of the time that the crops are in the ground or are unharvested, the practice of any trade or industry and the playing of all games is strictly forbidden. The Kabuis have a "genna" at which they wash the tired implements of their rude agriculture in a running stream, after which they hang them up till the next year.

There is another class of "gennas" to which I must draw your attention because of the peculiar ethnological interest which attaches to it. The prohibition against certain articles of food is described as a "genna," and in the same manner the rule which forbids a Naga to practise any trade or industry from the day of the "genna" which celebrates the beginning of the cultivating season to the day when they have the harvest-home festival is also a "genna." Now, these "gennas" are of general validity, and affect all the members of the community. The reason for "gennas" restricting the trades and industries may be the desire to give all the available energy of the village to the task of looking after the crops, while the effect of the "genna" rule, which disallows all fishing, hunting, playing, and sports, cutting of grass and timber, is to enforce a close season which is necessary.

The "gennas" which touch only classes of the village or clans are less numerous. Among the Tangkhuls, the clan is "genna" for the death of one of its members; while in certain villages I have found a "genna" necessitated by the death of a cat. The prohibitions with regard to dietary matters are complicated by much local variation, but girls who are unmarried, and women who are about to become mothers, are restricted in their range of diet.

An individual may make himself "genna" in many ways. For instance, a man who aspires to notoriety may decide that the state of his finances will allow him to erect a stone monument, and for the time he is surrounded by "gennas" of the same nature as those which protect the "khullakpa" from ceremonial impurity. Afterwards he gains certain prized privileges, such as permission to wear a chief's cloth, but he has to submit to restrictions which some of them find annoying.

Among all tribes a case of death brings a "genna" on the inmates of the house where it happens, and even if the death be that of an

animal, the "genna" is necessary. If a child is born in a house, the inmates are "genna" for at least one day, while the parents are "genna" for a period which may extend to four weeks. Some, not all, tribes, exact a "genna" for a birth of an animal in in the house.

The individual who is most protected by "gennas" is the "khullakpa," or the head of the village. He is the recognised intermediary between the greater powers and the people of his village. He officiates on all public occasions of worship, and it is necessary that he should be completely free from all ceremonial impurity, which would vitiate the rite entirely. If an epidemic sickness visits the village, he declares a "genna" and manages it. If rain has not fallen, he undertakes to propitiate the offended powers, and the whole village is "genna." He may not eat many things which are allowed to the common herd, and before all "gennas" commence he must not eat anything that has been cooked in an old pot. The Maos, alone of all the Naga tribes in Manipur, have a high priest who may not eat anything in a strange village, and it is a curious fact that there seems to have been a movement of dissent among the Maos some centuries ago according to their traditions, and now the headman of one group is anathema to the members of the separatist party.

A word or two about the sanctions of these "gennas." The first, and perhaps the most important thing, is that they are absolutely vague. No one knows the exact results of an infringement of any of the rules. It seems to me certain that within the mystery there are degrees of unimaginable penalties, for the rule against the intermarriage of members of the same clan is absolute, while there are other rules the breach of which can be condoned, or the results of a breach of the rule can be prevented by timely sacrifices. In no case is it within human knowledge to say how the spirits will deal with any case of disobedience, and, so far as one can judge, there is no difference between the sort of penalty that accrues from a disregard of the rule forbidding a woman to eat dog, and the result of a more flagrant act of defiance. The penalty may affect the guilty individual only, but it is quite as likely that a whole community will be punished for the sin of one, and guilty intent is no element in sin according to these ideas.

"Genna" is, therefore, not only a religious system, but it is the foundation of law among these people, and it provides the mechanism of their legal system as well. The separation of morality from religion, of law from religion, cannot take place in a state of society governed by such ideas as these, and when a Naga trusts his case to the arbitrament of an ordeal, he believes that High Heaven will punish the offender as surely and as mysteriously as in his belief it punishes those who break these rules.

Name-giving.

Before the end of the period of seclusion which follows the birth of a child in a house, a name has to be given to the new arrival. It is not necessary that this name should be that by which the child is to be known throughout his life, for the actual name may be chosen at a later date. The reason why a name must be given without delay is that the possession of a name is a protection against evil influences, which are especially active against young children and mothers at the time of childbirth. But the name has also an influence over the owner of it all through life, and care must be taken to see that the name is not unlucky. Therefore, they have recourse to omens taken from the dreams of the parents; to omens given by the condition of the fowls killed as an offering to the household deity at the child's birth; or in some cases they make the child the arbiter of its own fate by proposing names to it, and rejecting those at which it cries. One tribe has evolved a curious custom of giving names in accordance with a regular scheme determined by priority of birth, but there is some evidence for the belief that this system only conceals a private name which is strictly tabu, and if made public the only way of expiating the sin is to give a village feast and to assume another private name. As a result of this custom, the employment of nicknames is necessary to eke out the rather limited supply of authorised names.

Head Hunting.

One of the customs by which the hill people have earned an evil reputation is that of head hunting, and the raids in which they indulged were the reasons for the numerous expeditions which were sent against them, and which culminated in the occupation of the hills. I have been able to trace this custom to several causes. There is, firstly, the desire to provide a departed chief with a retinue of slaves in the future world, which accounted for the Kuki raids on the tea gardens of Cachar. Then

there is the very common belief that a human sacrifice brings fertility to the fields, and to this belief I attribute many cases of isolated murder. Village feuds account for many of the troubles, and, as it is a point of honour to keep up a feud as long as a head is owing from the hostile village, the difficulty of settling such feuds is great. Nowadays, when a village comes under British protection, one of the first steps taken by the officers in the hill districts is to persuade them to surrender all the heads in their possession, and in return to receive the heads taken from them. Finally, an episode which happened to me indicates another source of mischief. I once met in the hills a poor trembling wretch, who implored my help against the headman of a neighbouring village who was building himself a new house, and, to give it strength and stability, had cut a lock of this fellow's hair off, and buried it under the main post of the house. In the old days, I was told, the man's head would have been cut off and put there. Civilisation had so far produced a modification of the former custom, that only the hair had been cut off; but that was nearly as good, because they believed that the man's spirit would never rest until he had got the missing lock of hair back, and to get it would have to go underneath the house and be imprisoned there. I had the lock of hair duly disinterred, and it was burnt with proper ceremony.

Funeral Customs.

A word as to the funeral customs in vogue among the Nagas and Kukis. Both practice burial, and place in the graves the weapons and implements used by the deceased when in life. The graves of those who meet with sudden, violent, or mysterious deaths, are invariably dug by special classes of persons, with special protective ceremonies. The Kukis dispose of the bodies of their head men or chiefs in a remarkable manner. The corpse is placed inside a hollow log, which is then sealed down with mud. A pipe is inserted in order that the products of decomposition may be removed, and at the end of three months the covering is taken off and the bones dried and kept in the house. All erect monuments in commemoration of the dead, and while among the Nagas the direct intention of the monument is in some measure forgotten, many of the stone monuments in the vicinity of the Naga villages owe their existence to the desire for preserving the memory of the departed. The Kukis make an enclosure, inside which they place small stones in rows. The Tangkhuls erect stumps of trees inside the village, and stones outside; while the Koirengs —a tribe of Kuki affinity—erect cairns of a beehive shape. The largest stone monuments are those erected by the Mao and Maram Nagas. They are for the most part upright monoliths, about 12 feet high, a foot thick, and about 8 feet broad. Their weight must, therefore, be considerable. In the neighbourhood of the once large village of Maram is an avenue of stones, near which is a flat stone supported on three other stones. Every year before going out hunting the Nagas try their luck by kicking stones on it, and the man who first succeeds in lodging a stone on the top is regarded as likely to kill an animal. But the most remarkable collection of stones is that which exists in the neighbourhood of the tiny village of Uilong, two marches away from Maram. I have been told that I was the first British officer to visit this spot, and, from the absence of any description of the stones in earlier official records, I am inclined to believe this to be the fact. As I climbed up the hill, I observed by the side of the path a row of stones following the winding path about 18 inches in height. I then came to some stone steps which led to the ring of stones. There are 32 stones, arranged in a circle containing 14, with a single row of 18. These stones are of an average height of 10 feet, and are about 4 feet apart. The first stone is due east, and the people of the village dance inside the circle on "genna" days. There are many superstitions connected with these stones, and the whole village is "genna" during their erection, but since the diminution in their numbers the practice of erecting stones has fallen into desuetude. However, we are able to restore some of the customs from other villages where the stones are still erected. Tradition says that the Uilong stones were placed in position some 300 years ago. The descendants of the men who erected the stones in the first instance are believed to continue in prosperity so long as the stones stand, and in this belief may be found the reason why some of the Nagas offered very strong objections to the conduct of some Public Works subordinates, who used some of the fallen stones in the immediate proximity of the cart road as road material.

I have endeavoured to give as brief, and yet as complete an account as I could of the salient features of the beliefs and customs of the tribes inhabiting the State of Manipur. I

fear I have far exceeded the limits of space allowed by the rules, but I suffer from an *embarras de richesse.* I have touched on many matters, and if in one or two cases I have referred to what may be called politics, my excuse—and I hope it will be accepted—must be that I was always fond of touring amongst these people, and I soon learnt how necessary it was to deal with them direct, and to ascertain from their own lips their history and traditions. I used to take a magic lantern with me when on tour, and gave shows in every village, and I am now glad of this opportunity of redeeming a promise which I made to them, that I would tell my friends in England what I knew about my friends, the Nagas and Kukis of Manipur.

DISCUSSION.

The CHAIRMAN, in opening the discussion, said he could not stand in the way of others who, because of their personal and official knowledge of Assam, he hoped would address the meeting; but before taking the liberty of calling upon them to speak, he would wish to make two observations. One was to congratulate the Indian Section on the growing strength of the representation of India in the ever increasingly useful work of the Society of Arts. Each succeeding year the standard of the papers in the Indian Section rises higher and higher in literary quality, in practical utility, and public importance; and what was still more remarkable was the way in which Indian subjects were now being dealt with also in the other meetings of the Society of Arts. Only the previous night he had taken the chair, at the Ordinary Meeting, at the reading of a paper of rare interest and ability, on the architecture of Futehpur-Sikri, delivered by Mr. E. H. Hankin, and to-night it was his equal good fortune to preside at Mr. Hodson's lecture, one of the highest scientific value ever submitted to the Indian Section, and like Mr. Hankin's paper, delivered with a spontaneity, a dash, and an effectiveness that had held his audience, as did Mr. Hankin his, enthralled from start to finish. This was highly creditable to the Indian public services; and not less, he ventured to say, to the Society of Arts. It was also a matter of congratulation, in the highest interests of the public, that an institution which was doing such good work as the East London Technical College, should possess among its officials, a gentleman of Mr. Hodson's accomplishments, energy, and Indian experience. He hoped that these observations of his would be noted in India, for he was satisfied that nothing would be of greater practical advantage to the rising generation of the people of India interested in the acquisition of technical knowledge than that they should seek in yearly enlarged numbers to enrol themselves as members of the Society of Arts. The other observation he would desire to make was less altruistic and more egoistical. What had held him absolutely spell-bound, until, by what seemed the sudden close of the paper, he was awakened as from a dream, was the decorative patterns, embroidered and woven, on the clothing,—all true manufactures, and not machinations,—made and worn by the men and women of Manipur. This "Happy Valley" seemed to be not merely a reserve of historical antiquity, but of prehistorical humanity. He had heard with frequent pangs of resentful regret how already many of the primitive social habits of the Manipuris were being modified by our more direct rule over them: and he would only hope that it might be exercised for the future in such a manner as at least to conserve the archaic artistry—for this was not primitive—of their vernacular industries, particularly of their textile manufactures. The borderings of their robes and scarves, recalled those of ancient Egypt, and Babylonia, and Assyria. But one is always in terror—in ghostly apprehensions—of the exuberant and unabashed Vandalism of the imperial race which broke up into road rollers one of the rarest columns among the architectural relics of the Mo(n)gul period in India; which wantonly blew up the Jodhbai Palace at Futehpur-Sikri; which destroyed the paintings of the Ajanta Caves, by neglecting to keep the wind and rain, and "the moles (lizards) and the bats" out of the caves after breaking through the high heaped vegetable mould, the soft protecting hand of Nature, that for centuries had concealed, and protected, the entrances to them; which, again, through neglect of the copies taken of them by Major Robert Gill, 1824-52, left them to perish at the Crystal Palace in the disastrous fire of 1866; which removed the choicest remains of the Amravati Tope from the banks of the river Kistna to London, and and left them there to corrode in the open yard of Fife House for nearly 20 years, until he [the Chairman] got them transferred to the reverent custody of the British Museum; which recently cut down the avenue of sad cypress trees leading up to the mausoleum ["Taj Mahal"] of Shah Jehan at Agra; and which has now submerged Philæ [see the *Illustrated London News* of last Saturday, 18th March],—in the supersubstantial beauty of its moonlit loveliness of so spiritualising a witchery, one knew not whether it be of heaven or earth. Let us at least conserve Manipur as the Manipuris themselves have made it. In our Indian administration we should never forget that after all his wanderings in search of possibly better conditions of life, Rasselas at last returned gladly and gratefully to his own "happy valley" of Ambara.

Mr. H. LUTTMAN-JOHNSON said the reader of the paper had demonstrated a fact which he (the speaker)

learned a good many years ago, namely, that Manipur was one of the most interesting places on earth. When he first visited Manipur thirty years ago he thought he had never seen anything to compare with it in human interest. It was a crucible in which was to be seen man being stirred up as it were and coming out made. A well-known writer had written a book called "Mankind in the Making." He would advise that gentleman if he wished to see man in the making to go to Manipur. There were to be seen all sorts and conditions of men in their different stages, from the very primitive up to the more or less civilised Manipur. Dr. Grierson, a great philologist, had said that there were 147 different languages in India; he (Mr. Luttman-Johnson) thought there were a great many more himself; but in the hills round Manipur very nearly as many would be found. They were not separate languages from the philologist's point of view, but it would be found one village did not understand the language of the people in the next village. This meant that there must be an enormous number of languages, the development of which it was possible for a philologist to watch. He had taken a special interest in the paper, partly because he had been in Manipur and had served in the north-eastern frontier of India, and partly because the author, when he first went to India, was one of his assistants. Mr. Hodson always had an inquiring turn of mind, and it was very creditable to the Indian Civil Service that so many of its younger members not only devoted themselves to their duties as assistant magistrates and so on, but went out of their way to acquire an accurate knowledge of the districts in which they were stationed. He thought the paper showed that the author had devoted a large amount of time and taken an enormous amount of trouble in acquiring a very accurate knowledge of the languages, the customs and habits of the people among whom he was placed, and in that respect had done credit to the service to which he belonged. His own acquaintance with the people of Manipur was limited to occasional visits, but he knew the Manipurs of our own districts well. When the Burmese invaded Assam, about 1825, they drove out the original Manipuris, who flocked down into the neighbouring districts of Sylhet and Cachar, where they had remained to the present day. The present Manipuris of Sylhet and Cachar stated that the people in the valley of Manipur who had mixed with the hill tribes were not the original Manipuris, and that they themselves were the original race. He was sorry that the author said that the Manipuris in Sylhet and Cachar bore an evil reputation. He (Mr. Luttman-Johnson) saw a good deal of those Manipuris; they were to a certain extent turbulent, but the extraordinary thing was that from the point of view of civilisation they would be picked out from among the Mussulmans and Hindus of that district as the most civilised-looking; and, even when one got to know them, it was astonishing how advanced they were compared to the other people. For instance, the Chairman had mentioned their weaving and clothing. There was nothing among the natives of those districts at all to compare to the art of the Manipuris in weaving and ornamenting their clothes; it was absolutely unique. They were also fairly well-to-do. If the people in those districts were asked how it was the Manipuris were so prosperous, they replied it was because the women worked. Among Mussulmans the women were kept in the background. They did a good deal of work in planting rice, but were not encouraged to work in the same way as the Manipuri women were. For example, they did not go into the bazaar and sell things as Manipuri women did. The latter had acquired a position of freedom and independence which was uncommon in India.

Sir CHARLES CECIL STEVENS, K.C.S.I., said although he had no experience of Manipur, he had had a little experience of comparatively backward tribes on the western side of Bengal, in Chota Nagpur. He noticed several matters which the author had mentioned in which he detected an obvious, though possibly only a superficial, similarity. One thing that was common to some of the tribes of Chota Nagpur was the institution of a bachelors' hall, although the style of architecture was not the same. Another practice which they used to follow was that of jhuming, or burning the trees off the land. When the trees were burned, rice or a poor sort of Indian corn was sown, and also a sort of cucumber, something of the shape of a cocoanut with the husk on, and very nearly as large. The practice of jhuming was discouraged by his predecessor in the Commissionership, Mr. Hewitt, and he did his best to follow that example, because they felt that a time would soon come when the timber would be far too valuable to be dealt with in that way—and so it had proved. The Kol races in Chota Nagpur put up monumental stones, though he could not recall any instances of the systematic arrangement which the author had described. He recollected one such stone in the district of Singhbhum, in the south of Chota Nagpur, which was just upon twelve feet high, but of irregular shape. He also thought he detected in the physiognomy of many of the people a likeness to the physiognomy of some of the Chota Nagpur people. Another point of resemblance seemed to be the comparatively fragile nature of their houses. In Chota Nagpur that was observable the further away one got from head-quarters and from the purely British tracts; it was most marked in those houses which were on the borders of other native States, because property was not so secure there. The rulers were not very tender with their people, and a man who was being troubled by the ruler of his own State could slip away to a neighbouring State if he disliked his surroundings. But in their own districts there was more stability and houses were better.

Sir GEORGE WATT, K.C.I.E. (who presided over the latter part of the proceedings), stated that he went to Manipur in 1882, and remained there for nine or ten months, so that he had a certain knowledge of the country before the time the author went there. Only two or three Europeans had previously visited Manipur. Sir James Johnson was then the Resident, and he went up to join him, partly with the object of acting as medical officer to an expedition which was about to set out to demarcate the frontier, but mainly to explore Manipur as a botanist. He would like to mention one or two facts which he thought might be of interest. Manipur was an exceedingly beautiful little State. From his own knowledge of India he thought perhaps it was the most beautiful part of the whole of the Empire. He had been in Kashmir, in every province of India, and in every hill station, but he knew of no place that was half so beautiful. Not only was it beautiful artistically, owing to the magnificent hills with which it was surrounded, and its lakes and valleys, but it was exceedingly rich in its animals and vegetables. Probably no part of India had such a varied and beautiful flora. On going into Manipur the first thing that struck the traveller was the enormous number of trees with which he was not familiar in other parts of India. Speaking from memory, he believed there were probably twenty species of oak; and there were a great many other trees which were equally beautiful, interesting, and novel. For instance, Manipur was the home of the tea plant. To his mind there was no manner of doubt that the tea plant went from Manipur to China, Manipur being its original home. There were practically forests of tea trees, many of them of considerable height, and with leaves that would astonish anyone who knew what a cultivated tea plant was like. The leaves of the Manipur tea plant were often a foot or more in length. It was a most superb tree when in flower, and was one of the most beautiful trees of nature. Another interesting fact about Manipur was that it was the home of the silk-worm. He believed it highly probable that the real mulberry silk insect originated in Manipur, and from there went into China. There were many other instances of the kind that might be mentioned, showing the extraordinary influence Manipur had exerted on India and China. Manipur had been the half-way house between India and China far beyond historic times. There was one very remarkable feature about the country, namely, that the whole of the vegetation was depressed two or three thousand feet; but the cause of this no one had been able to explain. Taking, for example, plants that were well-known, certain species of rhododendrons that grew in Sikkim at about 14,000 or 15,000 feet, were met with on the north-eastern hills of Manipur abundantly at 7,000 to 9 000 feet. On the border between Manipur and the Naga Hills there were also four or five species of rhododendrons all behaving in the same remarkable way, showing that there was something in the climate of Manipur that was exceedingly peculiar. The whole of the typical plants of Sikkim were in Manipur, but at an altitude considerably below what they were in Sikkim. Then in the valley of Manipur, the peach, pear, and apple trees were cultivated, which would be quite an impossibility in any other part of India at the same altitude. There were also remarkable peculiarities about the animals, so that what the author had mentioned with regard to the extraordinary diversity of the people was only paralleled by the extraordinary diversity of the plants and animals. Every little valley in Manipur had a race of people of its own, a language more or less of its own, and, what was more remarkable still, a flora of its own. For instance, fourteen or fifteen miles away from the town of Manipur, not only was the vegetation entirely different but the rainfall was three or four times as great. Manipur was a land of surprises in every direction, and when he went there he revelled in it because it was so exceedingly interesting. The author had slightly disparaged the women of Manipur. He (Sir G. Watt) was inclined to think that many of them were very pretty. The young girls who sat by the roadside struck him as not at all bad-looking; and when he asked them one or two points on which he wished to be instructed their intelligence and happy natures fairly astonished him. They did their embroidery work without any pattern sketched on the border; they were apparently working without anything to guide them, and yet making those magnificent borders at the bottoms of their skirts which had been shown on the screen. In conclusion, he proposed a very hearty vote of thanks to Mr. Hodson for the exceedingly interesting and beautiful paper which he had given.

The resolution was carried unanimously.

Mr. HODSON, in reply to Mr. Luttman-Johnson's remarks that he had slightly disparaged the Manipuri residents in Cachar and Sylhet, said that if a robbery of any importance ever occurred in those places it was always stated that a Manipuri had done it. In reply to Sir Charles Stevens, he would point out that there were several types of houses. The Naga house was a very strong solid structure, which lasted for a good number of years, whereas the Kuk house was light and fragile, simply because they moved their villages every three years. When he was carrying out the census he had to go through the hills, and he found whole villages on the move. It took the natives about two days to build up a village of fifty houses, so that naturally enough they did not go in for building anything very solid. They also moved their villages for political reasons similar to those Sir Charles Stevens had mentioned. When a chief was powerful and popular, people would move to his village, and so long as that chief lived his village would grow and increase. Directly the chief died the village broke up, and the people went

through the whole process again. Sir George Watt did not mention in his interesting remarks about the fauna of Manipur that there were one or two rare species of birds and deer which were only found in that part of the world. For instance, the deer with the brown antler curving downwards and backwards was extremely rare. The evolutionary theory was that those deer, which were only found on the edges of the swamp, had grown curved antlers in order that they might be able to lift up the top of the swamp so as to browse underneath. There were at least two species of pheasants which were only found in the hills at one particular spot; one species was found in one valley and one in another, and were never known to cross over. That was an inexplicable fact.

Sir GEORGE WATT writes:—When I was called upon suddenly to take part in the discussion on Mr. Hodson's most interesting paper on Manipur, I forgot to mention one half the facts that might have been brought out by me. For example, with certain of the tribes, a plant is regularly cultivated to this day as a source of food that I think Manipur may safely be assumed to have been at least one of the centres of original cultivation. I allude to "Job's tears" (*Coix Lacryma-Jobi*). This is known to the Nagas as "ka-si," but far away in the Central Provinces it is "kesei," so also "kesai" in Guzerat, "kesai" in Berar," "kyeit," "kulese," and "kalinse" in Burma. These similarities one would think can hardly have been accidental, but rather denote knowledge in food-stuff that originated from a circumscribed locality from which also came its name. Now it is a curious coincidence (if that be all) that one of the earliest names for Manipur is "Ka-se," a word that in Burma was pronounced "Ka-the," and which became the Cassay of Dalrymple and other early European writers.

Whether this be a safe deduction or not, there is perhaps no aspect of ethnology that may in the future afford revelations of greater value than the study of the crops grown and plants eaten by aboriginal tribes. I give the example of *Coix* as suggestive only; but it is just possible that the distribution of that grain was conterminous with the invasion and conquest of India by the Mongolians, who crossed the North-East frontier and possibly passed through the little State of Manipur and carried the *Coix* into Assam, Bengal, the Central Provinces, and Burma. It is extensively cultivated to this day by people who are strongly Mongolian.

SEVENTEENTH ORDINARY MEETING.

Wednesday, April 5th, 1905; EDWARD WILLIAM BRABROOK, C.B, F.S.A., in the chair.

The following candidates were proposed for election as members of the Society:—

Ababrelton, Robert à, P.O. Box 322, Pietermaritzburg, Natal, South Africa.

Kinch, Walter S., Burtholme, Worthington, near Wigan.

Lucchesi, Andrea C., 2, Camden Studios, Camden-street, N.W.

The following candidates were ballotted for and duly elected members of the Society:—

Flack, Albert, 264, Borough High-street, S.E.

Pierera, A. A., Alexandra Institute, Hyderabad, Deccan, India.

The paper read was—

ANCIENT ARCHITECTURE AT GREAT ZIMBABWE (RHODESIA).

By RICHARD N. HALL, F.R.G.S.,

Part author of "The Ancient Ruins of Rhodesia," and author of "Great Zimbabwe."

I wish to direct attention to what is admitted to be the greatest archæological wonder of the Southern Hemisphere—the ancient temples of the Great Zimbabwe.

This group of prehistoric buildings lies in South-East Africa at over two hundred miles from the shore of the Indian Ocean at Sofala. Its name is derived from *Makuru Zimbabigi*, or "The Great Buildings of Stones," the title applied to these ruins by the native race of Makalanga, or "People of the Sun," who inhabit Mashonaland and the country of the Great Zimbabwe.

Zimbabwe was known to the very early mediæval Arab traders on the Mozambique coasts, who gave descriptions of these ruins to the Portuguese, and in 1552, De Barros made the first recorded mention of their existence.

From mediæval times until 1868 the existence of these buildings appears to have become completely lost sight of. In that year Adam Renders, an elephant hunter, rediscovered the Great Zimbabwe, but so scanty and so highly coloured were the descriptions of these buildings then given that the scientific world looked askance at their discovery.

It was not until 1871, when Dr. Karl Mauch examined these ruins, that their discovery was treated seriously by the archæologists of Europe. It was then ascertained that their discovery by Adam Renders was but a rediscovery of these ruins, and that the archives of the Vatican and of Lisbon contained earlier information concerning them.

In 1891 Mr. Theodore Bent examined the ruins and embodied his report in "The Ruined Cities of Mashonaland." His account is ex-

ceedingly valuable and reliable, but, unfortunately, he only saw the ruins in their buried condition. Later, other writers, including Dr. Schlichter, a German archæologist, and Sir John Willoughby, added further to our knowledge of this group of ruins.

In 1902 I explored the Great Zimbabwe on behalf of the Government of Rhodesia. This work extended over two years, and the report to the Government on my explorations and discoveries is now embodied in "Great Zimbabwe," a volume forming a natural sequence to "The Ancient Ruins of Rhodesia," of which I shared the authorship with the late Mr. Neal.

Since my return to England last autumn I have had opportunities of discussing before leading scientific bodies at home several phases of the Zimbabwe problem, such as the origin of the ruins, the evidences of ancient civilisation and arts, the mediæval and modern records concerning them, and the progress made within recent years in researches regarding these ancient monuments.

Ancient Architecture.

But among the many aspects from which the great Zimbabwe problem may be considered there was one which I had not as yet submitted for discussion, and this was the all-important subject of the architecture and construction of these buildings as represented by the temples at Zimbabwe.

In the consideration of their style of architecture and methods of construction will, in most probability, be found a reliable key to the final solution of the enigma these marvellous structures present to the archæologists. But first it was necessary to bear in mind that the whole of Southern Rhodesia lying between the Zambesi and Limpopo rivers yields abundant evidence that in some prehistoric times the country was occupied by a dense population of colonists, thought to be Semites of South Arabia, who were engaged in a gold-mining industry of almost inconceivable extent, and which represented an occupation extending over very many centuries of time.

Ancient gold mines exist in all the auriferous districts of Southern Rhodesia, covering an area of 600 miles from east to west and 500 miles from north to south. Associated with these ancient gold mines are buildings undoubtedly erected for the main purpose of defence, obviously suggesting by their architectural features and massive construction that these prehistoric colonists occupied by force in a hostile country. Certain of these buildings are now believed to have been erected to serve the further purposes of religious worship and solar and astral observation. Some of these structures evidently were capital centres of gold-mining districts, others protected extensive gold workings, while others are found in chains protecting certain well-defined routes throughout the country and also leading towards the coast.

The Great Zimbabwe, by its evident importance and great extent, was undoubtedly the ancient metropolitan centre for the whole of the country. There are at least five hundred distinct ruins of buildings throughout Southern Rhodesia, and of these descriptions at least two hundred are to hand. These buildings are of all ages and periods extending from prehistoric times down to within the last few centuries. These various classes of ruins present different types of architecture, and yield relics belonging to different periods of antiquity, and generally occupy distinct areas of country. But it is with the most ancient type of buildings, as represented by the Great Zimbabwe, that archæologists are most concerned.

Possible Age of Zimbabwe.

There appears to be unanimity in opinion among many leading scientific men of Britain, Germany, and France, that the age of the Elliptical Temple at Great Zimbabwe, and of the associated ruins of a similar style of architecture and construction, dates back to some period between 1600 and 1100 B.C. This opinion is based on several grounds, some of which may briefly be stated:

1. The striking parallelisms existing between the architecture and plan of the Great Zimbabwe and those at least of two ancient temples in South Arabia, as to the remote antiquity of which latter there is no doubt.

2. The orientation of the three Zimbabwe temples and of some score of other ruins in Rhodesia determined independently by British and German scientists, all point to the probable age of many of the buildings being from 1600 to 1100 B.C.

3. The discovery at Zimbabwe of the zodiacal signs showing the sun in Taurus, which astronomers assert represents a period which could not date later than 1600 B.C.

4. The undoubted practice at Zimbabwe of nature worship of an exceedingly old cult believed to synchronise with that period.

5. The absence from Zimbabwe of all sign-writing, the earliest inscriptions found in any Phœnician temple being not older than 700 B.C.

6. The evidences at Zimbabwe of ancient civilisation and arts whose only parallel in many respects, especially in their associations, is to be found in the ancient kingdoms of south Arabia.

7. The evidences of ancient gold-mining operations, distinct from those of mediæval Arabs and Portuguese, of an inconceivably vast extent, showing a total output of gold in prehistoric times of at least £75,000,000 sterling, which mining operations geologists and mining experts show were conducted at a most remote period well synchronising with the estimated ages of the oldest of the Zimbabwe buildings.

8. The presence throughout Southern Rhodesia, and especially on the ancient mines and ruins area, of trees and plants which are not indigenous to South East Africa, and which still bear their fruit in the early spring. But additional internal evidences from the ruins and mines in Rhodesia could be advanced, also external evidences obtained by scientific research in the Near East, the Mozambique coasts and Madagascar, from ethnological and anthropological examinations, and also from Arab traditions.

With these evidences should also be taken into account the inability of scientific men, and especially of geologists, to point to any country or combination of countries other than Rhodesia, which could have yielded the enormous wealth of gold, which according to ancient Roman and Grecian historians, and the Scriptures, and modern research, was so plentiful in all the ancient empires of the Near East.

Rhodesia, it is now admitted, contains the most extensive ancient gold mines known to the world.

Having suggested in mere outline the probable ages of the Zimbabwes, I will now deal with their appearance, plan, architecture, and construction.

Appearance of Ruins.

Immediately on viewing the great Zimbabwe for the first time every visitor, even the most casual, is greatly impressed by the extraordinary massive proportions of its grandly sweeping walls. Undoubtedly the Elliptical Temple is a most awe-inspiring structure. Its appearance powerfully suggests the Near East.

The European student of architecture, to entertain any adequate idea of the oldest type of forts and temple-forts in Rhodesia, must first dismiss from his mind all conceptions of the distinctive features of Grecian, Roman, and Egyptian styles of architecture.

I was assured by professors and students of Egyptian archæology that the plan, architecture, and construction of Zimbabwe finds absolutely no parallel or similarity with the plan, architecture, and construction of any known Egyptian building. This is obvious to any one visiting Zimbabwe.

In Rhodesia the ancient architecture provides no sculptured columns and ornate capitals, no arches, and no basilica, but conical towers and monoliths enclosed within stupendous walls laid on an elliptical plan—all unroofed from the very date of their construction and all open to the light of heaven.

So far as archæological researches lead the ancient buildings in South Arabia—of Yemen, the ancient empire of Saba, alone present any parallel with those of Zimbabwe, and in several of their most important features of architecture an identity is believed to have been established.

Plan.

The plan on which the oldest of the Zimbabwe buildings throughout Southern Rhodesia are laid is always elliptical. Walls are built on curves, and the ends of walls, sides of entrances and buttresses are rounded. The angular form of building is absent, and is only found in the case of structures of obviously much later periods.

Main Walls.

The walls are very substantially built with bases averaging from 7 feet to 16 feet in width, and are beautifully and most skilfully constructed not only on the exterior faces but in the internal portions. Levelling instruments must have been used at Zimbabwe.

Each wall has a lean-back or batter-back on either face. Thus the main east wall of the Elliptical Temple is 16 feet wide at its base, but at a height of 30 feet its summit is 8 feet in width.

The average batter-back of high walls of the oldest type is one in ten to one in eight, though one in six is often met with in lower walls.

Building Materials.

The building material employed at Zimbabwe is local granite in blocks, with faces averaging nine by seven inches. Many of the

blocks have been rudely squared by the use of diorite hammers, some having been cut with metal tools.

Building Material.—How Obtained.

One might ask how the ancients obtained the enormous quantity of building material. Was it by quarrying in the local hills? I am of opinion that no quarrying, in the ordinary sense in which the word is employed, was carried on by the ancients. All the evidences are strongly to the contrary. Caves occupied by the ancients could have been considerably enlarged and their accommodation greatly increased by simple quarrying operations, but the caves remain in their natural state. Rock protuberances in the floors of some of the ruins have not been removed, but permitted to remain, even to the extent of inconveniencing the occupiers. The hills in the Zimbabwe district show no signs of any quarrying operations on the part of the ancients.

The hills and cliffs which abound round the Zimbabwe valleys are granite. These are mainly whaleback in shape, and layers of granite in some stage of decomposition cover the faces of these hills, and whaleback cliffs with gigantic scales, the layers being about six to nine inches in thickness. At the bases of these hills and cliffs are hundreds of tons of scale rocks or slabs, broken fairly square by their fall from great heights. These are flat top and bottom, and only require slight trimming, if any, on their sides to make them fit closely together, and so form the ordinary block of granite as seen in the walls. These gigantic scales from the faces of the cliffs are always falling, especially after long rains; the roar and crash of these falling masses of slabs can at times be heard from our camp in several directions. No doubt the ancients finding so conveniently situated these extensive masses of fallen scales of rock, almost suiting their purpose without much labour except for their transport for two or three miles only, used these blocks in building, trimming their sides when necessary. Possibly they assisted to loosen these slabs from their original position on the cliffs in order to increase the supply of materials.

The granite used in the walls is all local, but lithologists state that the ruins on Zimbabwe Hill (350 feet), are mainly built with a local granite which does not correspond to the class of granite yielded by the formation constituting the hill itself. We may be assured that the great majority of these blocks in the extensive "Hill Ruins" was carried up to the summit from a distance of two or three miles. This implies an employment of slave labour of great proportions, but the ruins elsewhere as well as the ancient gold mines all point unmistakeably to the same conclusion. At least over 100 tons of slate used in the buildings have been carried from a distance of ten or twelve miles, the nearest point of the slate formation to Zimbabwe being about ten miles.

The soapstone extensively found at Zimbabwe must have been imported from a distance of twelve or twenty miles, that being the nearest soapstone formation to Zimbabwe. The huge granite monoliths are believed to have been carried by slaves from the Lumbo district some two miles distant. Each of these would have required an immense number of slaves even to lift it from the ground.

Dry Masonry.

No cement or mortar has been used in the construction of the walls, all these being of dry masonry. The ancients extensively employed a fine granite cement for floorings, steps, and dadoes. In their more important dado work, the dadoes have had an outer layer of whitish soapstone clay brought to a high polish.

Passages.

One extraordinary feature at Great Zimbabwe is the extent and number of passages, amounting, so far as they have been discovered, to a length of over 5,000 feet, of which over 2,000 feet in length were discovered during the recent explorations. The heights of the side walls are from five feet to thirty feet, while some are sunk below the level of the ground. All are very narrow, some being only shoulders' wide.

Each temple has an important passage; these are conjectured to have been the approach of the priests to the inner shrines or sacred enclosures. The lowest floors of these passages yielded great quantities of religious emblems and articles of gold.

At Zimbabwe the ancient architects laid down a splendid system of drainage, which must have been contemplated before the outer main walls were erected. The buildings were open and never roofed, but by this system the flooding of the temple during sub-tropical rains was prevented.

[Mr. Hall then proceeded to describe with the aid of lantern views the conical towers, platforms, mono-

liths, carved stone birds, and mural decorations found at Zimbabwe, and the various periods and styles of construction and successive occupations of these ruins.]

DISCUSSION.

The CHAIRMAN, in proposing a vote of thanks to the reader of the paper, said he had admirably described the altogether unique remains which had been excavated with so much skill and patience. It was a very curious circumstance that the period referred to of something between 3,000 and 4,000 years ago was a time at which, in many parts of the world, a great deal of knowledge and attention seemed to have been given to astronomy, and proficiency in art and mechanical appliances, and that there were, dating more or less back to that period, in many parts of the world, monolithic and other remains of great magnitude, which caused the envy of modern people in their endeavour to imagine how they were brought together. Among those remains there were few more startling than those which the author had described. The beauty of the curvilinear form, the ease with which simple devices for adornment had been adopted, and the taste of the whole of the features of the remains were exceedingly striking. The labour which must have been necessary to collect together such massive structures as the solid buttresses and conical towers was enormous. The subject had been described in the most lucid manner by the man to whom great credit was due for having done the work, and it had been illustrated with a splendid collection of lantern slides, in which the scale of the immense structures was shown by workmen engaged in the operations being included in the photographs. The great buildings in the Acropolis were even more startling than those in the Elliptical Temple, because of the immense difficulty which must have been experienced in building them up to their great height. The paper had also encouraged the feeling, which was now so common in regard to most things, that the old was better; that whenever really good work was found, in which every stone was laid with absolute precision, and in which the curves were beautifully arranged, it was the older work, and that the clumsy and loose work was the more modern. It seemed at first sight to contradict the expectations of some people that things were improving as time went on, but it undoubtedly was the case with regard to any kind of art which had been brought to great perfection in ancient times, that when subsequent alterations were found they were very inferior.

Mr. RICARDE-SEAVER said that although he had not been to Zimbabwe he knew a good deal about it, the first he heard of the interesting ruins there being from his old friend, the late Mr. Cecil Rhodes, who showed him some of the wonderful birds which were discovered there. In his subsequent trip to Egypt, the late Mr. Rhodes endeavoured to find similar birds, but was not successful in his search. Mr. Rhodes spent a good deal of time and money in connection with the remains at Zimbabwe, but during his lifetime very little of real value or interest was found. Although Mr. Bent and Mr. Swan had done very good work at Zimbabwe, he thought the author, and Mr. Franklin White, were to be thanked for elucidating many of the problems which appeared at the time of Mr. Bent's visit to be entirely obscure. He had no doubt that if the author returned to Zimbabwe, and if there was further exploration work to be done, he would on a future occasion place some more interesting data and information before the members.

The CHAIRMAN said he believed those who went to the meeting of the British Association in South Africa later in the year would have the opportunity, if they cared to avail themselves of it, of visiting the ruins at Zimbabwe, and of being conducted over them by Mr. Hall, and this would certainly be not the least of the attractions of that memorable visit.

The resolution of thanks having been carried unanimously,

Mr. HALL, in reply, thanked the members for the vote and also for the sympathetic attention they had given to his paper. He would have liked to have made the subject more popular, but as he anticipated a discussion he restricted the description of the ruins. Nobody had attempted to answer the question as to who the ancient architects were. There was no doubt, both from the ruins themselves and from the mines, that the architecture was not evolved in the country, but introduced in its best forms. The mines also showed that mining on a large scale with shafts was introduced direct into the country and not evolved. There were also evidences that the country had routes, some leading direct to and near the coast. One route, about 200 miles in length, was defended at every four, six, eight, or ten miles by forts, especially in ravines and gorges, and at river drifts. He thought that showed that the people were colonists, the fortifications proving that the people were occupying a country where force and defence were necessary. The knowledge of solar and astral matters pertained to all the Semitic nations of the Near East. Babylon gave the world the signs of the Zodiac. Those old Semitic nations of Mesopotamia, Chaldæa, Phœnicia, Canaan, Arabia, and Babylon, had a profound knowledge of astronomy, and it was doubtful whether we now possesssed the knowledge that those ancients once had. In the temple it was conjectured that some principles of mensuration and geometry were employed. The old Semitic nations had given to the world not only the signs of the

Zodiac, but the foundations for Mercator's sailing tables, its knowledge of astronomy, and even the terms used in the navy, such as admiral, dinghy, prow, and a score of others; and it was a country so highly civilised that it gave the basis of the Phœnician language, which was the mother of all European systems. He did not think there was any doubt that the old nation of the Sabæans were, according to the Scriptures, ancient Grecian and Roman historians, and modern research writers, the gold purveyors of the then-known world. Ezekiel said, "The merchants of Saba were thy merchants; they occupied all thy markets with gold;" and the Psalmist said, "The Kings of Saba shall offer gifts, and unto him shall be given of the gold of Saba." That indicated that, in the Hebrew mind at any rate, the old Sabæans represented the highest ideal of wealth in gold. They had not yet explained what had become of the gold in the country, unless they attributed its extraction to the old Sabæans, who were known to have had colonies throughout the whole length of East Africa, and who had a monopoly of trade in the Indian Ocean. He would have liked to have heard some discussion on that point, on which he was merely a learner.

Mr. R. Phené Spiers writes:—Whilst willing to bear testimony to the admirable construction of the walls as shown in Mr. Hall's magnificent slides, I am unable to admit that the title of architecture can be correctly applied (as we understand the term) to the buildings of the great Zimbabwe. The question of stone walls in circular or elliptical forms, with raking sides and rounded angles is not architecture, in fact, the Zimbabwe construction never seems to have gone beyond its first elementary creative stage. Mr. Hall referred, however, to three decorative patterns, which he said are among the earliest ever adopted, these being the *herring-bone* pattern, the *dentelle*, and the *chevron*. The first, however, is not a pattern at all: it is only a method of laying masonry or brickwork. When the material is of thin dimensions, as is the case with tiles or slates, it is found easier to lay it in sloping courses, but *in order to make it sound construction, these tiles, slates, or thin courses of stone must be embedded in mortar*, and as the builders of Zimbabwe never used mortar, it is evident they never built herring-bone masonry. There was only one instance in which it had been found on the upper part of a wall, and from its appearance in the photograph, this was probably a late addition, and could not be called a pattern any more than the ordinary cresting of an English wall. *Dentelle* is the French for lace, and as evidently that is not meant, the word is probably a corruption of the word *dentil*, which is a well-known architectural term applied to the imitation in stone of the ends of squared timbers which project in front of an architrave or beam to carry a roof. But the projections shown in the slides are those employed when blocks of stone are placed edgewise on the top of a wall carrying slabs of stone straight in advance of the wall beneath. This is a type of finish to a wall which was largely employed by the Sassanians, and when, as in one of their later works at Rabboth Ammon, they employed this same indentation round an arch, it bore the closest resemblance to what is known to us as the dog-tooth ornament, which is so largely found in Norman work. The "dog-tooth course" would be, therefore, a better term to employ. But on the western temple platform in the acropolis a photograph was shown of a series of vertical indented shafts, incorrectly termed columns, built in coursed masonry. These appeared to be about 20 feet high, but, if I understand correctly Mr. Hall's description, they measure only 3 feet 6 inches high. They may have been enclosed with a border, and constituted a panel decoration only. The chevrons of the exterior face of the south-east wall are an admirable termination of the same, and it would have been difficult to conceive a more happy design than this, which gives dignity and scale to what is certainly a magnificent wall. Whilst differing from Mr. Hall as to the title of architecture which he claims for the Zimbabwe constructions, and to a certain extent to the nomenclature applied to the patterns, I beg to bear testimony to the great interest of the researches which he has undertaken. They give architectural value to those made some years ago by Mr. Bent, though Mr. Bent's work settled many problems respecting which there was some doubt.

MOTOR VEHICLES.

The motor car would have been a familiar object generations ago but for the sustained opposition of local authorities and those whose interests related to horse haulage. Invented towards the close of the eighteenth century, and pronounced perfectly practicable by a Parliamentary Committee of 1832, in 1834 a motor car attained a speed of 34 miles an hour, and ran long distances at an average of 24 miles an hour. For the first forty years of last century the contest between rail and road locomotives was strenuous and the result doubtful, but after 1840 there was a temporary cessation in the manufacture of road cars. It was not until 1857 that practical men took them up again, believing that they could be worked with great advantage to the community. Then Parliament intervened.

In 1859 a Bill was introduced imposing heavy tolls upon motor carriages. It was referred to a Select Committee and fell through, but in 1861 an Act was passed which, among other restrictions, prohibited motor carriages being propelled at a greater speed than ten miles an hour in the country and five miles an hour in towns. But inventors were not dis-

couraged, and by 1865 many improvements had been made in the machines. Then Parliament dealt a crushing blow, prescribing in an Act of that year that each locomotive should be conducted by three persons, that the maximum speed should be four miles in the country and two in towns, and that it should be forbidden even to blow off steam. Power was also given to the local authority—usually hostile—to fix the hours during which the machine might be used. In 1878 the same authority was enabled to make by-laws and to charge a fee not exceeding £10 for a license to use motor carriages. These Acts were created to deal with heavy traction, but in 1881 the Court of Queen's Bench placed every type of self-propelled vehicle under the limitations indicated.

Hitherto motor carriages had been propelled by steam alone, but now gas engines were invented and petroleum engines proposed. Thereupon Parliament set itself to make it difficult to try these new powers, and did so by widening the Acts which hitherto had only applied to steam engines. Thus, in the Act of 1878 a locomotive was defined as "a locomotive propelled by steam, or by other than animal power." Nor were the county authorities more disposed than Parliament to welcome the motor car. In 26 counties the full license fee of £10 was demanded. In only six was the fee as low as £6. If a person travelled in a motor car from London to Newcastle he had to take out nine several licenses, and they cost him £85. It took him a week at least over the journey, not because his machine would not go quicker, but because the by-laws regulating the traffic were seldom alike in any two counties. It was necessary for him to get nine sets of these by-laws since he had to cross nine counties, and his groom had to walk in front of him the whole way with a red flag.

The inevitable result followed. From 1878 onwards for many years inventors were confined to the manufacture of heavy locomotives. In 1881 Sir Thomas Parkyn caused a steam tricycle to be constructed, but he was immediately prosecuted although his machine emitted no steam, and made so little noise that the policeman who gave evidence respecting it was doubtful how it was driven. The magistrates were bound to enforce the law, and the sentence was ratified on appeal. Parliament, local authorities, courts of law, all seemed combined to throttle one of the most useful inventions of the age, with the result that this country was left behind in mechanical traction by France, Germany, and the United States, whose agencies were handicapped by no such restrictions.

It was not until 1896 that Parliament was persuaded to take a more friendly view of motor cars. The chief prohibitory clauses of the Acts named above were then repealed and the Locomotives on Highways Act of that year first gave motorists the right to drive motors on the public roads. This Act was considerably modified and amended in the motor interest by the Motor Car Act of 1903, which came into force at the beginning of 1904. This Act prescribes the speed at which motors may be driven, prohibiting a greater speed than 20 miles in the country, or more than 10 within any limits or place referred to in the regulations made by the Local Government Board. The provisions of the Act are too well known to need recapitulation here, but it may be said that motorists have no longer reasonable ground of complaint against the Legislature.

The change in the attitude of Parliament towards the motor-car was quickly followed by an immense development of the motor industry, which shows no signs of slackening. France still leads the way but England is no longer discreditably behind continental nations, and, indeed, a British motor car now holds the world's record for speed, and what is of equal consequence, reliability. In all directions the motor is revolutionising practice. The Prime Minister has given it as his opinion that it will solve the housing problem by carrying the workman into the country at a cost within his means. But that time is not yet. It can hardly be said that prices are on the down grade. The average value of the car now manufactured is lower than it was two or three years ago, but this is due to the introduction of a lighter vehicle. The exhibitors have plenty of motors ranging in price from £500 to £1,500, bulky and luxuriously appointed machines averaging from 20 to 35 horse-power each. But the Trade is also putting on the market patterns which can be sold at much lower figures. It is quite possible to get a machine for £100, but rather curiously there is no demand for it; the lowest priced machine for which there is any sale costing £125. Petrol, steam, and electricity are the power agents in use, but electricity is practically confined to town vehicles, the public seem to distrust steam, and for the present petrol is almost universally used.

There is certain to be a large increase in the number of motor cars and machines in use in the near future. To give a single indication as to cabs, the London Express Motor Service, Limited, has just ordered from the Herald Manufacturing Company of Manchester 100 hansom cabs, and many hansom cabmen are attending classes on automobile management and driving. The omnibus question is a much larger and more contentious one. It is claimed for the motor omnibus that it is more convenient for the public and likely to be more profitable to shareholders than the electrical tramway. It is a very complicated question which cannot be gone into now, but it is safe to say that motor omnibuses have come to stay, that for many suburban districts, for sparse populations, and for narrow streets they are better than trams, that in the City, where trams are impossible, they will be a boon, and that many of the smaller provincial towns will regret that they are tied to tramways. It may be noticed in this connection that last month the Wolverhampton Tramways Committee decided not to lay down a tramway to Renn Fields but to serve the locality by means of motor omnibuses.

Motor cars are beginning to be used very largely for agricultural purposes. If a farm is to pay in these days there must be efficiency and economy in its management, and motors have now been brought within the reach of the man farming on a moderate scale, whilst in cases where half-a-dozen small farms are near enough to each other informal syndicates have been formed for the purpose of purchasing a motor machine for all round work, to be used by all in turn, and they are proving a magnificent investment. The motor can do pretty well everything on a farm, except pick fruit and clip hedges. Nearly everything in the way of cultivation and harvesting can be done by it at a saving of from 30 to 50 per cent. And so with railways. Already the motor is of great advantage to them as feeders. The North Eastern Railway Company was the pioneer in this direction. In 1903 it introduced motor cars on two lines included in its system, the first between the Hartlepool and the West Hartlepool Stations, which at once became a success. In October of the same year a motor car service was inaugurated by the Great Western Railway Company between Chalford and Stonehouse, a distance of a little over six miles, which was covered at hourly intervals, with six intermediate stops, in 23 minutes, the fare being a penny a mile. This was followed by the London, Brighton and South Coast Railway Company running a service between Brighton and Newhaven across the sea front of the South Downs, a picturesque and breezy drive of nine miles; and now in all directions we see the railway companies feeding, or preparing to feed, their systems by motor carriage. As for cartage the horse is hopelessly distanced. A leading manufacturer gives the following illustration. One wagon on building contractors' work carts brick, cement, general joinery, &c., making four journeys per day, a distance of $3\frac{1}{2}$ miles, with an average load of $5\frac{1}{4}$ tons, returning $3\frac{1}{2}$ miles light each journey, for two weeks $5\frac{1}{2}$ days each, and two weeks 5 days each, two half days per fortnight taken for cleaning, &c., a total of 21 days, giving a ton mileage of $1{,}533\frac{1}{2}$, and 294 light miles, the total cost, including interest on £550 at 5 per cent. for one month working out at £23 9s. 4d., or 3·6d. per ton mile $\times$ $3\frac{1}{2}$ miles, $=$ 12·6d. per ton per journey, against the lowest cartage rates by horses available for the same work of 2s. 3d. per ton, thus giving a balance of 1s. 2d. per ton in favour of the motor wagon.

During the last two or three years there has been a striking increase in the number of motors used for municipal purposes. Hindered at the outset by the police, who made trouble as to the height and width of the vehicles, and then by the Local Government Board asking that locomotives on the highway weighing over two tons should not exceed a speed of five miles—it has since been increased to eight—motors are now being used for dust collecting, street cleaning, and watering, and in other ways, and are rapidly ousting the Corporation horse. "The three hundred weight hammers of the horse," says Mr. Higgins, the Borough Surveyor of Chelsea, "wore out the roads at least twice as quickly as the vehicle he drew, required an army of scavengers in turn to wait on him, and was largely responsible for the house-fly pest." When kept constantly at work with the minimum of time occupied in collecting and loading, the motor is not only cheaper than horse service, it causes much less wear and tear of roads than horses.

The Post Office authorities are not generally credited with any great partiality for innovation, but they have done all in their power to encourage inventors to produce a motor suitable for the carriage of mails. For three or four years past they have used motor vans as letter carriers, and their motor service is being rapidly extended. Reliability is the first condition of everything connected with Post Office work, and there is a big fortune for the firm that first turns out a motor van that fully meets the stringent conditions of the Department. The canal companies are among the slowest to adopt the motor as a substitute for canal-barge propulsion, and consequently, except in a few cases where steam tugs are employed, the barges on the canals of Great Britain are still horse-drawn, but they are not likely to remain so. In Belgium, France, and other countries where up-to-date ideas, if they are good, are more quickly adopted, the canal owners better appreciate the motor. Thus, on the Nivernais canal, which extends for over 100 miles, between the Loire and the Yonne, in France, there is a motor barge "length" of $2\frac{1}{2}$ miles on which a Florat motor successfully and easily drags heavy trains of barges at a much greater speed than a horse would travel, and with heavier loads.

THE DECAY OF THE CHICORY INDUSTRY.

Efforts are being made by Yorkshire growers to induce the Chancellor of the Exchequer to readjust the methods of charging the Excise and Customs duties upon chicory. Fifty years ago the production of chicory, for mixing with coffee, was a rural industry of some importance in certain districts of Yorkshire and other counties of England, but during the past thirty years the home-grown supply of this article has, with occasional fluctuations, gradually diminished until it has become a negligible quantity in the produce markets of this country. At one time chicory was grown and dried on farms not only in Yorkshire, but also, on a smaller scale, in Nottinghamshire, Lincolnshire, and Cambridgeshire, and the industry is said to have yielded large profits, and to have given employment to a considerable number of men, women, and children. The development of this rural industry prior to 1853 was, however, favoured by fiscal conditions, inasmuch as imported raw or kiln-dried chicory was subjected to a Customs

duty of 20s. per cwt., and there was no Excise duty on the home-grown article. In 1853, Mr. Gladstone reduced the duty on foreign chicory to 4s. per cwt., and entirely abolished it in 1854, from which date until February, 1860, imported raw or kiln-dried chicory was allowed to come in free.

The withdrawal of the duty on foreign chicory was a blow to the growers in this country, and they had hardly adjusted themselves to the new conditions of competition when the industry was again disorganised by the imposition of an Excise duty, the actual amount of which was less disturbing than the regulations connected with its collection at the country kilns. This duty was first imposed in 1860 when home-grown chicory was charged at the rate of 3s. per cwt. Next year it was raised to 8s. 6d., and in 1862 to 11s. The Customs duty in 1860 was 6s. per cwt., and in 1861 and 1862 it was 12s. In 1864 the Excise duty was fixed at 24s. 3d. per cwt. on home-grown chicory, and at the same time a Customs duty of 26s. 6d. per cwt. was placed on the imported article. In 1872, when the coffee duty was reduced by 50 per cent. the rates on home-grown and imported raw or kiln-dried chicory were fixed at 12s. 1d. and 13s. 3d. respectively, and have since remained at these levels.

The imposition of an Excise duty checked the sowing of chicory, and after the readjustment of the duties in 1872 the home production steadily declined. The farmers' kilns were eventually dismantled and devoted to other purposes, and the drying of the roots became a monopoly in the hands of the merchants, to whom the few farmers who still continue to grow chicory have for some years sold their roots in a raw state. The largest quantity brought to charge before the change in the duties in 1872 was 20,611 cwts. in 1866-7. At that period the area under the crop in Great Britain was approximately 600 acres, of which 400 and 500 acres were situated in the neighbourhood of York. The crop was abandoned in Northamptonshire in 1871.

The use of chicory in this country seems to have steadily diminished. Thus in the year of largest production, 1866-67, while the quantity of home-grown chicory on which duty was paid was, as has been stated, 20,611 cwts., the foreign chicory entered for consumption, raw or kiln dried, was 83,941 cwts., making a total of 104,552 cwts. But although in 1903 the home production had fallen to 1,674 cwts., the foreign importation was only 76,926 cwts., reducing the total to 78,600 cwts., and this in face of an immense increase in population. In 1895 the area devoted to the crop in Belgium was 929,976 acres; it has since declined to 16,843 acres.

It is complained by the growers of chicory that there are certain differences in the methods of collecting the Excise and Customs duties on chicory that operate to the disadvantage of the home industry. The Excise duty is collected on the kiln-dried chicory, and charged on its weight as removed from warehouse for roasting. The Customs duty is collected on the landing weight of the imported chicory. The British grower has to dry and store his roots under Excise regulations, whereas his Belgian competitor is free from any restrictions of this kind. In compensation for this disadvantage there is a difference of 1s. 2d. per cwt. between the rates of Excise and Customs duties in favour of the home-grown product. But the compensation is said to be insufficient for various reasons. (1). Difference in assessing the Excise and Customs duties. In Yorkshire it is the custom to dry the chicory on the kilns for 24 hours, at the expiration of which it is weighed off and removed into warehouse under the supervision of the Revenue officers. By this process of drying the root loses almost exactly 75 per cent. of its weight, so that a ton of cut root yields approximately 5 cwts. of dried chicory. The duty of Excise is charged, however, not on the weight of the article as removed from the kiln, but on the quantity weighed out of warehouse. In the warehouse the chicory, which frequently lies there several months, absorbs a certain amount of moisture from the atmosphere, and by assessing the duty on the weight of the article on its removal from warehouse instead of on its weight when deposited in warehouse the Excise charge on the accumulated moisture. The Customs, on the other hand, charge the duty on the landing weight of the imported chicory, even when the article is deposited in warehouse, so that the foreign article bears no excess duty from moisture accumulated in bond. (2) Most of the kiln-dried chicory exported from Belgium is subjected to a second drying immediately before shipment, which is known as "high-drying," which reduces its weight by about 20 per cent., so that each hundredweight of Belgian "white-dried" chicory, which would have paid 13s. 3d. in duty before being "high-dried," actually pays when imported in the "high-dried" state about 10s. 8d. If these figures are compared with the Excise duty of 12s. 1d. on Yorkshire "white-dried" chicory, it will be seen that by purchasing the "high-dried" imported article, the roaster in this country saves 1s. 5d. per cwt., or 28s. 4d. per ton in duty alone. In this way not only is the margin of 1s. 2d. per cwt. between the Excise and Customs duties swept away, but there is a gain of 1s. 5d. on every cwt. of imported "high-dried" chicory used in preference to the home-grown product.

It is now being urged that so long as Belgian "high-dried" chicory is allowed to pass the duty as kiln-dried at 13s. 3d. per cwt., the duty on the "white-dried" home product should be so modified as to remove the disproportionate charge it at present bears in relation to the duty imposed on the imported "high-dried" article. This system would seem to have the support of Mr. Crawford, whose exhaustive and authoritative "Report on the cultivation and drying of chicory in Great Britain" (Cd. 2,169) should be read by all interested in the subject.

CORRESPONDENCE.

BRITISH WOODLANDS.

Sir Dietrich Brandis points out that two passages in his remarks in the discussion on Sir Herbert Maxwell's paper, printed on page 540, col. 2, should stand as follows:—

Lines 10-14: "It is difficult to obtain the financial results of forest management in private estates, and this is one of the reasons why private proprietors do not take up the question."

Lines 32-36: "In connection with rabbits, the speaker desired to say that in some enclosures of Richmond-park he hoped now to see young oaks coming up from self-sown seed, which would have been impossible while millions of rabbits were there."

Dr. John Nisbet writes:—

It would have given me great pleasure to have been present at the reading of Sir Herbert Maxwell's excellent paper on "British Woodlands," on 29th March, and to have made a few remarks in support of its main proposals.

When Mr. Hutchins's paper on "National Forestry" was read during the session 1899-1900, I pointed out that any vast scheme of national planting, as therein recommended, was entirely out of the question (even in the very improbable case that funds might become available) and that technical instruction in forestry must be the first step towards improvement, and any ultimate prospect of planting for profit on an extensive scale. Partly as the result of the Forestry Committee's report in 1902, much has been done, both privately and by Government, to provide adequate instruction at different educational centres, and further results are pretty certain to be noticeable in the near future. But technical instruction alone will not solve the problem of planting waste land extensively with profit, and of helping to provide supplies of home-grown timber for future use.

If there is ever to be any great scheme of planting in the United Kingdom it must be undertaken by the State, and if it be desired to induce landowners to plant with a view to profit, then it is certainly the primary duty of the State to provide (1) a practical object-lesson as to how to plant waste land with profit, and also (2) to provide landowners with reasonable inducements to plant, partly in the way of providing easements from existing burdens falling on plantations, and partly in assisting them to obtain the necessary funds on easy terms that would not press unduly on the life-interest enjoyed in the estate by the present landowner.

To discuss any of these latter points would be quite beyond the purpose of my present remarks; but as regards the planting of waste land, I very cordially support Sir Herbert Maxwell's recommendation that the State should acquire 1,000 acres (and far more than that when they are about it) and plant it on business principles, and on a well-considered scheme. In fifteen to twenty years this could provide the much-wanted object-lesson of how to plant waste land with profit; and after the total loss of £10,000 on the recent absolute failure of the Knockboy Plantations in one of the congested districts of Ireland, the duty of the State to furnish some such object-lesson has become all the more imperative. This is far more necessary than the purchase of woodlands (as recommended by the Forestry Committee, 1902) in connection with technical instruction.

Sir Herbert's estimate of £6 an acre all round seems a very fair one; and it would even cost much less than that if the land happened to have good natural drainage and a light soil, where the cheap method of notching could be employed. No doubt about £7 an acre would in most cases completely cover all outlay for draining, fencing, clearing and preparing the ground, planting, and beating up blanks in the first two years till the plantations can be considered established. Fencing, a very expensive item in small plantations, decreases rapidly per acre when planting is done in extensive blocks. Thus, for fencing in squares at 6d. per trimming yard, the total and proportional expense varies as follows:—

Area, acres.	Total yards of fence.	Total cost of fence.	Average cost per acre.	
		£	s.	d.
1	280	7	140	0
4	560	14	70	0
16	1,120	28	35	0
64	2,240	56	17	6
256	4,480	112	8	9
1,024	8,960	224	4	4½
4,096	17,920	448	2	2¼

With regard to future forecasts of the value of the timber crops, I venture on no remarks. The timber prices of the future are likely to be far higher than they are now, or than they ever have been; but they are too uncertain to form any suitable basis for an actuarial calculation. No doubt the relative value of different kinds of timber will alter considerably. When one can for about 4d. a cubic foot impregnate comparatively low-priced woods like pine, spruce, silver fir, beech, birch, poplar, &c., with creosote, naphthaline, or saccharine substance, so as to render them far more durable than unprocessed larch or oak, then certainly, for outdoor work at least, this tends to equalise the future market value of these different classes of wood; and the economic question then becomes one in which the total bulk of the crop is of perhaps equal importance with, or even greater than, the value of the product per cubic foot. Actuarial forecasts are, therefore, things to fight shy of.

On one point I do not altogether agree with Sir Herbert Maxwell. The Continental and Scandi-

navian winds may blow as violently as—or even more violently than, so far as that is concerned—the storms that sweep over our islands; but we are exposed to violent gales from every point of the compass to a far greater extent than Continental countries.

"Our own periodical losses in the British Isles are heavy every ten or twelve years; while in Germany it is calculated that, at a low estimate, windfalls average about 1,225,000 cubic feet annually. The most destructive storms recorded there during the last fifty years took place in December, 1868 (when over 245,000,000 cubic feet were thrown), in October, 1870 (when over 390,000,000 cubic feet were thrown), in March, 1876 (over 154.000,000 cubic feet), in February, 1894 (over 105,000,000 cubic feet), and on 31st January and 1st February, 1902 (over 58,000,000 cubic feet)."

But at the same time our generally wind-swept and totally unprotected waste land will be very hard to plant with profit until a sufficiency of broad shelter belts or plantations can provide shelter for growing new plantations more extensively.

In respect of the planting of waste land and of the amount of employment woodlands afford to rural labour, the latter being a point particularly referred to by Sir Herbert Maxwell, it may prove of interest to the members of your Society to know what importance foreign Governments attach to national work of this special kind.

Cimiez, Nice, 1st April, 1905.

[Dr. Nisbet refers to some "Notes on Continental Forestry," prepared by him for the "Transactions of the Royal Scottish Arboricultural Society, 1905" for the information mentioned in the last paragraph.]

OBITUARY.

WILLIAM PAUL.—Mr. Paul, the eminent horticulturist of Waltham-cross, died on the 31st ult., in the 83rd year of his age. He was elected a member of the Society of Arts in 1880, and in April, 1889, he read a paper before the Society on "Fruit Culture for Profit in the Open Air in England." He was associated with Robert Fortune in the introduction of the tea plant into India. As a practical cultivator of flowers he was best known by the many new and improved forms of roses which he brought into existence. His work, "The Rose Garden," was first published in 1848, and the latest edition—the tenth—is an exhaustive treatise on the subject. Mr. Paul was the founder of the Royal Nurseries at Waltham-cross, which enjoy a wide reputation. Members will remember the charming exhibitions of roses which were arranged by Mr. Paul for the Society's conversazioni in the Botanic Gardens.

THE HON. SIR DAVID TENNANT, K.C.M.G.—Sir David Tennant died on 29th ult. at his residence, 39, Hyde Park-gate, aged 76. He was for 30 years a member of the Legislative Assembly, Cape Colony, and was Speaker from 1874 until 1896, when he came to London to assume the duties of Agent-General of the colony, a position which he continued to hold until 1902. He was closely identified with the educational life of Cape Colony, and was for some time chairman of the council of the South African College and a member of the University council. He was knighted in 1877, and created a K.C.M.G. in 1892. Sir David was a member of the Society of Arts since 1897. He was a Member of the Committee of the Colonial Section, and presided at one of its meetings in 1899.

WALTER MORESBY CHINNERY, J.P.—Mr. Chinnery, a well-known member of the Stock Exchange, and president of the London Athletic Club, died on the 29th ult. at his residence, Hatchford-park, Cobham. He was born in 1843, educated at Eton, and became a distinguished athlete, winning the Mile and Four Mile Amateur Championship in 1868 and 1869. He was Deputy-Lieutenant of Surrey, and had recently been elected High Sheriff. He became a member of the Society of Arts in 1904.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

APRIL 12.—"The Industrial Resources of the State of Matto Grosso, Brazil." By GEORGE TORRANCE MILNE, F.R.G.S. COLONEL GEORGE EARL CHURCH, F.R.G.S., will preside.

MAY 3.—"Recent Excavations in Rome." By MRS. BURTON-BROWN.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

MAY 11.—"The Manufactures of Greater Britain. —III. India." By HENRY JOHN TOZER, M.A.

MAY 18.—"Plague in India." By CHARLES CREIGHTON, M.D.

COLONIAL SECTION.

Tuesday afternoons at 4.30 o'clock:—

MAY 23.—"The Cape to Cairo Railway." By SIR CHARLES H. T. METCALFE, Bart., M.Inst.C.E.

APPLIED ART SECTION.

Tuesdays, at 4.30 or 8 o'clock:—

MAY 2, 4.30 p.m.—"The Monumental Treatment of Bronze." By J. STARKIE GARDNER. SIR GEORGE BIRDWOOD, K.C.I.E., C.S.I., will preside.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, APRIL 10...Civil Engineers, 25, Great George-street, S.W., 8 p.m. (James Forrest Lecture) Col. Rookes Evelyn Bell Crompton, "Unsolved Problems in Electrical Engineering."

Surveyors, 12, Great George-street, S.W., 4 p.m. Mr. H. M. Cautley, "Farm Buildings."

Geographical, University of London, Burlington-gardens, W., 8½ p.m.

Camera Club, Charing-cross-road, W.C., 8½ p.m.

Medical, 11, Chandos-street, W., 8½ p.m.

TUESDAY, APRIL 11...United Service Institution, Whitehall, S.W., 3 p.m. Col. The Right Hon. Sir J. H. A. Macdonald (Lord Kingsburgh), "The Volunteer in 1905."

Asiatic, 22, Albemarle-street, W., 3 p.m.

Royal Institution, Albemarle-street, W., 5 p.m. Mr. Percival Landon, "Tibet." (Lecture II.)

National Service League, Caxton-hall, Westminster, S.W., 5½ p.m. Lord Newton, "The National and Imperial Advantages of Universal, Naval and Military Training."

Medical and Chirurgical, 20, Hanover-square, W., 8½ p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. William Marriott, "The Maintenance and Strengthening of Early Iron Bridges."

Colonial Inst., Whitehall Rooms, Whitehall-place, S.W., 4½ p.m. Sir Frederick Pollock, "Imperial Organisation."

Horticultural, Vincent-square, Westminster, S.W., 3 p.m. Mr. T. J. Powell, "Retarded Potatoes."

WEDNESDAY, APRIL 12...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. G. T. Milne, "The Industrial Resources of the State of Matto Grosso, Brazil."

Naval Architects (at the HOUSE OF THE SOCIETY OF ARTS), John-street, Adelphi, W.C., 12 noon. 1. Address by the Chairman, The Right Hon. the Earl of Glasgow. 2 Mr. W. E. Smith, "The Design of the Antarctic Exploration Vessel *Discovery*." 3. Colonel N. Soliani, "The Armoured Cruisers *Kasuga* and *Nisshin* of the Imperial Japanese Navy." 4. Mr. Herbert Rowell, "The Russian Volunteer Fleet."

Biblical Archæology, 37, Great Russell-street, W.C., 4½ p.m.

Japan Society, 20, Hanover-square, W., 8½ p.m. Mr. Marcus B. Huish, "England's Appreciation of Japanese Art."

Royal Literary Fund, 7, Adelphi-terrace, W.C., 3 p.m.

British Archæological Association, 32, Sackville-street, W., 8 p.m.

THURSDAY, APRIL 13...United Service Institution, Whitehall, S.W., 3 p.m. Col. H. Le Roy-Lewis, "The Yeomanry in 1905."

Mining and Metallurgy, Geological Society's Rooms, Burlington-house, W., 8 p.m. 1. Mr. Gustav Köller, "The Kedabeg Copper Mines." 2. Mr. T. Kirke Rose, "Refining Gold Bullion and Cyanide Precipitates with Oxygen Gas." 3. Mr George M. Douglas, "Wood Gas for Power Purposes and Gas Generator." 4. Mr. Philip Poore, "Notes on the Prestea District—Gold Coast Colony." 5. Mr. R. O. Ahlers, "Notes on the New Dharwar Gold Field of India." 6. Mr. James Park, "The Cause of Segregation in some Igneous Magmas."

Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Royal Institution, Albemarle-street, W., 5 p.m. Prof. R. Meldola, "Synthetic Chemistry." (Lecture II.)

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. 1 Discussion on Mr. Duddell's Report on the International Electrical Congress at St. Louis. 2. Mr. F. Creedy, "The Alternating Current Series Motor."

Historical, Clifford's-inn Hall, Fleet-street, E.C., 5 p.m.

Numismatic, 22, Albemarle-street, W., 7 p.m.

Mathematical, 22, Albemarle-street, W., 5½ p.m.

FRIDAY, APRIL 14, 1905.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

PROCEEDINGS OF THE SOCIETY.

EIGHTEENTH ORDINARY MEETING.

Wednesday, April 12th, 1905; COLONEL GEORGE EARL CHURCH, F.R.G.S., in the chair.

The following candidates were proposed for election as members of the Society:—

Cole, Dr. J. W. E., Mwomboshi River, North-eastern Rhodesia, South Africa.
Hall, William Henry, Statistical Department, Sydney, New South Wales, Australia.
Hawdon, Joseph William, 16, Windsor-road, Denmark-hill, S.E.
Kiralfy, Imre, Tower-house, Cromwell-road, S.W.
Longden, Henry, 447, Oxford-street, W.
Meintjes, Laurens Schmitz, African Farms, Ltd., Maribogo Station, British Bechuanaland, South Africa.
Moore, James, 17, Donegall-place, Belfast, and The Finaghy, Balmoral, Belfast.
Newcomen, A. Gleadowe, Messrs. Cooper, Allen and Co., Cawnpore, India, and Messrs. Allen Bros. and Co., 14, Devonshire-square, E.C.
Parker, Walter Edward, A.M., 217, Haverhill-street, Lawrence, Massachusetts, U.S.A.
Tilley, James Walter, F.C.S., 95A, Southwark-street, S.E.
Weeks, Rufus Wells, "Devonbrink," Tarrytown, New York, U.S.A.

The following candidates were ballotted for and duly elected members of the Society:—

Arnold, W. Hacker, Messrs. H. Whitlock and Co., Holland-gate, Kensington, W.
Gibbons, William Pike, J.P., C.C., Ruiton-house, Upper Gornal, Staffordshire.
Habibullah, Khan Bahadur Md., Vellore, North Arcot District, Madras, India.
Henley, Mrs. A. L., 7, Oxford-square, W.
Jack, Stuart Maclean, 42, Victoria-road, Upper Norwood, S.E.
Jackson, Walter Geoffrey, Prestwick, near Witley, Surrey.
Macdonald, David Baird, F.C.S., 127, Evington-road, Leicester.
Ridley, Frank R., 10, Russell-street, Covent-garden, W.C.
Scholes, William, A.R.C.Sc., F.C.S., 102, Victoria street, Radcliffe, Lancs.
Taylor, Thomas, Rosendale, Newcastle-under-Lyme.
Wilkinson, Henry Ernest, 31, Priory-park-road, Kilburn, N.W.

The CHAIRMAN, in introducing the reader of the paper, said that the subject of the paper was the vast area of Central Brazil known as Matto Grosso, a region more than two and a half times the size of France. Although its rivers had been to a large extent explored, the interior parts of the country were still *terra incognita*. The author had lived in Matto Grosso for several years, and had paid great attention to its mineral wealth, its industrial resources, and its future possibilities.

The paper read was—

THE INDUSTRIAL RESOURCES OF THE STATE OF MATTO GROSSO, BRAZIL.

By G. T. MILNE, F.R.G.S.

The name of Matto Grosso, or "dense forest," was given in the seventeenth century by the Portuguese adventurers, known as "bandeirantes" or "sertanistas," to the country extending from the north of what is now the State of Goyaz, Brazil, to the head waters of the river Guaporé. The discoveries of gold which they had made in Minas Geraes stimulated the ambition of these pioneers to push their explorations further towards the west, and when, after being accustomed to the comparatively open country of the highlands of Saõ Paulo and Minas Geraes, they met with a wide belt of thick forest extending westwards for hundreds of miles, the change in the physical features of their surroundings doubtless suggested the name. How far the whole territory now known as Matto Grosso answers to the description may be inferred from the fact that in the southern part of the

State there are wide tracts of open country adjoining the rivers Saõ Lourenço and Paraguay, while the great central table-land is also more or less open.

In the sixteenth century the Spanish adventurers had sailed up the river Paraguay on their journey to Peru, but there can be little doubt that the general exploration of Matto Grosso was not begun until more than a century later by the Portuguese.

Situation and Area.

The State of Matto Grosso lies between 7° 30′ and 24° 10′ of south latitude, and between 50° 35′ and 65° 10′ west of the Greenwich meridian. It occupies the most central part of South America, and is bounded on the north by the States of Pará and Amazonas, on the west by the Republic of Bolivia, on the south by the Republic of Paraguay, and on the east by the Brazilian States of Goyaz, Minas Geraes, Saõ Paulo, and Paraná. It is nearly four-and-a-half times the size of Great Britain and Ireland, its area of more than 533,000 square miles entitling it to rank as second only to Amazonas, the largest of the twenty States forming the Brazilian Republic.

Physical Features.

The main physical features of this vast territory are the low-lying open grass lands of the south adjoining the river Paraguay and its tributaries, the table-land forming the central part of the State, and the forest belt already mentioned. The south may be said to form part of the vast plain extending northwards from the Pampas of Argentina through the eastern portion of Bolivia. This plain, roughly described, stretches as far west as the Andes, as far north as the great central plateau of Brazil, forming the water parting between the Amazon and the River Plate, and as far east as the elevated land masses forming the southern extension of that table-land. As showing its gradual declivity towards the River Plate, it may be mentioned that, according to the engineers engaged by the Bolivian Government in the delimitation of the frontier with Brazil in 1878, the river Paraguay is only 288 feet above sea level at Corumbá, although at this point distant more than 1,600 miles from Monte Video. During the rainy season, which lasts from November till April, the river Paraguay and its tributaries overflow their banks and flood the adjoining plain for an enormous distance. This part of the country then presents the appearance of an inland sea, and travelling, which in normal conditions can be done on horseback, has then to be done by canoe. When the rain ceases in the region drained by the Upper Paraguay, the pressure exercised by the water in the main channel is withdrawn, and the repressed waters on the plain then escape. Owing to this circumstance, the phenomenon is presented of a river rising during its lower courses when the upper levels are subsiding.

This flood plain is generally open and covered with pasture; it supports thousands of head of cattle, which during the period of flooding are driven off to higher land. The black soil appears to be admirably suited to the cultivation of rice. Isolated masses, forming hills which rise from the plain, are occasionally met with, notably near Corumbá, and further north near the banks of the river Paraguay.

The table-land I have mentioned extends across the State in a W.N.W. direction from Goyaz to the cataracts of the Rio Madeira. Its eastern portion, which is known as the Chapada, a name commonly used in Brazil to denote a table-land, also extends towards the south until it joins the hills of Paraguay, while the western portion is known as the Serra dos Parecis (from the tribe of Indians of that name), and the Cordilheira Geral or General Range. From the latter there is an extension towards the north lying to the west of the Tapajos River, known as the Cordilheira do Norte or Northern Range, but this portion of the State has been very imperfectly explored, and existing maps are more or less conjectural with regard to it.

This plateau rises in some places to a height of nearly 3,000 feet above sea level, and it has been remarked that the wide plain below looks like a sea from its edge, while the escarpment with its inlets and promontories bears a curious resemblance to a coast-line. Commenting on this resemblance, Dr. John W. Evans, who visited Matto Grosso in 1891, says, in a valuable paper on the geology of the State contributed to the quarterly journal of the Geological Society for February, 1894, that it is not necessary to have recourse to marine action for an explanation of the present configuration of the country. As seen from Cuyabá, the outline and form of the precipitous cliffs of reddish sandstone of the table-land, distinctly visible in the clear atmosphere at a distance of 40 miles, form a striking feature in the landscape, while the view from the edge towards the plain is certainly suggestive of the sea as observed from

cliffs. Towards the north the table-land is believed to sink gradually towards the Amazon Valley, but the land separating the rivers flowing north, is, as I have before indicated, only imperfectly known. The table-land may be regarded as forming the water parting between the river Amazon and the River Plate.

Towards the end of the eighteenth century, Luiz Pinto, Captain-General of Matto Grosso, attempted the canalisation of a short tract of country separating the Alegre and the Aguapehy—tributaries respectively of the rivers Guaporé and Paraguay—with the idea of opening direct communication between the Plate and the Amazon, but the project was abandoned. In the quaint language of his despatch to his royal master in Lisbon, "the equinoctial sea is united with that of the 36° parallel of southern latitude by a canal of 3,500 leagues formed by nature." His project was grand in conception, but I fear that it would prove practically impossible of execution except for navigation of the smallest craft.

The country of the plain more immediately adjoining the plateau is somewhat undulating in character. The formation is generally clay slate, with but a thin layer of vegetable soil overlaying it. The vegetation is poor, the grasses being harsh and unsuitable for pasturage, while the trees are stunted in growth. The slates, which are traversed by numerous quartz reefs, are sometimes overlaid with a cemented deposit composed of quartz pebbles and iron oxides, locally known as *canga*. It is in these formations that the early pioneers of Portugal found auriferous deposits of such extent and value as led them to found the present capital, Cuyabá, and other mining centres in the State.

On ascending the table-land somewhat different conditions obtain. Here the slates are overlaid by sandstones, and the soil is generally of a dark red colour. The undulating surface is in parts covered with thick coarse grass, which if better in quality than that of the slates is inferior to the rich pasture of the flood plain, while there are tracts (such as parts of the Serra dos Parecis) which are sandy and barren in character. The table-land is generally lightly timbered except along the water courses. Excellent coffee is raised at the village of Sant Anna da Chapada on the table-land near the Capital, and the land generally may be regarded as being more adapted to agricultural than to pastoral pursuits.

The forest from which the State takes its name is thoroughly tropical in character, and presents similar features to the great Amazon forest further north, of which indeed it may be regarded as the southern expression. There one finds the Hevea, yielding Pará rubber, vanilla, balsam of copaiba, jaborandi, Brazil nuts, several kinds of palms, and an infinite variety of trees and plants yielding valuable timber, fibres, dyes, and medicines. The climate and soil are alike totally different from those of the table-land and river plains, and the natural products are correspondingly modified. The whole State is a perfect elysium for the botanist, so rich and varied is the flora. Among other workers in this field, Mr. Spencer Moore, of the Natural History Museum, South Kensington, has rendered valuable service to botanical science by a contribution to the Transactions of the Linnean Society, December, 1895, embodying the results of his work in connection with an expedition to the country in 1891-92.

To those in search of sport, the country offers more attractions than many other parts of South America—jaguar, puma, tapir, antbear, camp and forest deer, and wild pig are all to be met with, as well as numbers of smaller animals, while winged game is varied and abundant.

CLIMATE.

The main factors determining the climatic differences of the State, are the division of the wet and dry seasons, and the differences in altitude. The rains in and about the valley of the Upper Paraguay begin about October or November, and continue until about April or May. The amount of rainfall is considerable, especially in the forest belt; but in Cuyabá, the capital, it is less. As the result of three years observations in Cuyabá, Dr. Morsback states in the "Revista do Observatorio," published at Rio in 1890, that the annual average amounted to 1,166 mm.; this is between 45 and 46 inches. Thunderstorms usually accompany the rains. During this period the heat is considerably less than in the dry season. The maximum of heat is probably attained in the month of September—*i.e.*, immediately preceding the rainy season. The mean annual temperature at Corumbá is, according to the Belgian Consul there, 29° Cent., but that of the capital is lower. According to observations published in Dr. João Severiano da Fonsecá's work, "Viagem ao redor do Brazil," the mean annual temperature at Cuyabá for 1876 was 25·71° Cent., and for 1877, 26·72°.

The forest region is hot and damp, and the

river plains are also hot, but not so enervating. When we ascend the table-land a delightful change is at once apparent. Here the climate is bracing as compared with the other districts, even at midday a fresh breeze mitigates the heat of the sun, while the nights are decidedly cool.

As regards health, malarial fever is more or less prevalent in the forest belt and in the river valley, while goitre is noticeable among the inhabitants on the plateau. The fact that yellow fever is unknown confirms what has often been stated, viz., that it is never found far removed from the sea-coast. Speaking generally, the table-land may be considered decidedly healthy and admirably suited as a place of residence for Europeans, while I always found the capital, which is 720 feet above sea-level, to be quite healthy.

Population.

The population of this vast territory probably does not exceed 90,000, not including the wild Indian tribes of the interior, as to which exact data are not available. It is composed mainly of Brazilians descended from the early Portuguese settlers, whose living representatives, however, show marked evidence of contact alike with the negroes introduced as slaves from Africa and with the aboriginal Indians. Most of the foreigners settled in the State, such as Portuguese, Italian, or German, are engaged in trading. The labouring classes are nearly all native Brazilians, a few Bolivians and Paraguayans being also met with. The educated native here, as in many other parts of Brazil, while sometimes engaged in agricultural or pastoral pursuits, or in commerce, often limits his ambition to securing a post under Government when his party is in power.

Many years ago the late Baron of Melgaço, an authority on all matters relating to Matto Grosso, calculated that the wild Indians numbered 25,000, forming eighteen separate tribes. If this estimate were at any time reliable, one may safely assume that the total number is now less, as intertribal wars tend to reduce the number, and the untamed Indian tends to disappear before the encroachment of civilisation on his domain. Some of the tribes are stated to be anthropophagous, and several are well-known to be hostile to the white man; as an instance of this, I may mention that some few years ago a personal friend of my own was killed by an Indian arrow when travelling in the forest near the old City of Matto Grosso. Some of the more peacefully-inclined tribes engage in agriculture, forming large clearings in the forest, while others live on the fish that abound in the rivers, or live by the chase. They are mostly of Tupy stock, and at no time appear to have arrived at a degree of civilisation at all comparable with that of the races ruled by the Incas in Peru or Bolivia.

Rock picture writings are found at Gahyba, on the river Paraguay. These appear to be crude representations of the heavenly bodies, serpents, a human hand and foot, and palm leaves, and they are similar in character to the rock pictures met with in other parts of Brazil. Whether they are the work of a race long since extinct, or of the ancestors of the present Indian tribes, is a question difficult to determine. It may be noted that it is somewhat doubtful whether the aborigines understood the value of gold when the early pioneers of Portugal invaded their country.

Means of Communication.

A glance at the map will show that the State is extremely well watered, but, unfortunately, many of even the largest rivers are at some part of their course so impeded by rapids as to prevent, or seriously interfere, with navigation. Especially is this the case with the rivers flowing north towards the Amazon. In compensation these very obstacles may, in some cases, be one day utilised to generate electrical power for railways linking up river stretches open to navigation. At present the sole means of water communication with the exterior is by the river Paraguay and its tributaries. Leaving Monte Video, one can sail northwards by steamer for a distance of over 2,000 miles to Cuyabá, successively navigating the waters of the Paraná, Paraguay, Saõ Lourenço, and Cuyabá, while the Paraguay itself can, during the rainy season, be navigated by vessels of light draught to within a few miles of the ancient mining centre of Diamantino.

The Brazilian Government maintains a bi-monthly service of mail steamers by the former route, the voyage from Monte Video to Corumbá occupying about ten days. From Corumbá to Cuyabá the voyage occupies about five days and is performed by light draught steamers. A few small steamers are also engaged in carrying freight. Freights from Monte Video to Corumbá average about £2 3s. 6d. per ton, while those from Corumbá to Cuyabá run to over £5 per ton. Beyond Cuyabá navigation is obstructed by rapids, but

it seems probable that by the expenditure of a little energy and capital it might be opened as far as Rosario, a small town some eighty miles further north.

RAILWAYS.

So far nothing has been accomplished in the way of railway construction within the borders of the State, although, even in the time of the Empire, various projects were laid before the authorities and concessions granted. The need for a line connecting Cuyabá with the Federal capital at Rio is apparent on strategic grounds, because, in the event of complications arising with the Argentine Republic, Brazil might find her access to Matto Grosso through the Paraná-Paraguay river system closed, as happened during the Paraguayan War, when all goods had to be brought to the capital by mule-trains from Rio. The need is further emphasised in the event of revolutions breaking out in Matto Grosso, as has occurred more than once since the fall of the Empire in 1889.

The Mogyana Company's trunk line through Saõ Paulo and Minas Geraes has reached Catalao in Goyaz, and it is intended that it should ultimately be prolonged to Cuyabá, but in the event of this extension being unduly delayed in execution it seems probable that the Federal Government may itself construct the line.

A combined railway and navigation scheme, which when executed will have an important bearing on the future of Matto Grosso, as well as Goyaz, is that dealing with the Araguaya and Tocantins rivers. A concession has been granted to a Belgian syndicate for the construction and exploitation of a railway from Alcobaça to Praia da Rainha to compass a stretch of the river Tocantins, encumbered with rapids to such an extent as to render navigation impossible. Navigation is already open by steamer between Pará and Alcobaça. The terms of the concession include both federal and State subventions for navigation, and like guarantees of interest on cost of construction of railway, while in addition the syndicate will receive free grants of land adjoining the route amounting to about 100,000 square kilometres, and preference in equal conditions in the working of all mines located in a zone of 40 kilometres on each side of the route. The district traversed by the route is said to be rich in rubber, and in the State and city of Pará Goyaz, and Matto Grosso would find a ready market for the surplus cattle from their plains, while there is room for millions of settlers on the healthy table-land of the two last-mentioned States. The scheme would afford the most direct route of all between Matto Grosso and Europe or the United States, bringing Cuyabá within 200 kils. of a point of free navigation on the Rio de Mortes, a tributary of the Araguaya.

Another scheme of importance to Matto Grosso is that which contemplates the construction of a railway round the falls of the Madeira. It is one of the oldest railway projects connected with the State, the first concession having been granted more than thirty years ago. More than one attempt has been made to carry it out, but hitherto without success. It now appears, however, that in the recent re-adjustment of frontier with Bolivia, Brazil has undertaken that this road, so necessary to Bolivia as an outlet towards the Atlantic for the produce of her eastern provinces, shall be constructed within four years. When it is, the Guaporé and Mamoré rivers will be more extensively navigated than is possible at present, and the whole of the western portion of the State, which is believed to be rich in rubber as well as minerals, should then be opened up.

At present nearly all the internal transport, where not effected by water, is done by pack mules or oxen. These mule, or bullock trains, laden with rubber or agricultural produce, are frequently met with when travelling in the interior, as, although of late years the State Government has done something towards improving the roads, these are, as a rule, unsuited to wheeled traffic; and it is only in one or two districts, that the heavy covered-in carts, with solid spokeless wheels, drawn by four or five yoke of oxen, are met with. One can always tell when a bullock cart is approaching long before it is visible, by the continuous singing sound caused by the wheels revolving on ungreased axles, it being an article of faith among the drivers of such vehicles that were the creaking sound to cease the bullocks would cease to pull!

Transport by ox-cart or pack-mule or bullock is tedious—only from 20 to 30 miles being covered in a day. At sundown a camp is formed near a stream, the animals are turned loose to graze, and the men sling their home-spun cotton hammocks, which form an indispensable part of their equipment, among the trees. Frequently several hours are spent the next day in rounding up the animals, when the journey is resumed. Sometimes the night is passed at a farmhouse, where old-fashioned, but none the less genuine, hospitality is ex-

tended to the traveller and his dependents. When one is fortunate enough to travel on horse or mule back, unencumbered by pack animals, it is possible to cover 50 or 60 miles in a day.

Telegraphic Communication.

Telegraphic communication has existed for some years between the capital and Rio by means of an overland line, and quite recently a service has been established between Cuyabá and Corumbá.

Agriculture and Extractive Industries.

Agriculture is generally in a very backward state, so much so is this the case that although the total population does not exceed 90,000, excluding the wild Indian tribes of the interior, staples such as flour, rice, maize, and beans are imported from the exterior. This is partly due to lack of labour. When slavery was finally abolished in Brazil in 1888, many fine estates went out of cultivation in Matto Grosso, and could, a few years ago, and probably can still, be purchased for the proverbial song. By the abolition of slavery the economic position in Brazil was profoundly modified, and the more inland parts of the country have not yet recovered from the effects of so radical a change. The year following the abolition, saw the downfall of the Monarchy, and this was followed by a period of political unrest, culminating in some instances in disturbances of a kind only too common in South American countries. A situation was created far from favourable to the attraction of either capital or immigrants. Especially was this the case in Matto Grosso, which the tide of foreign immigration reaches but slowly, while Argentina, already well-known to emigrants from Southern Europe, stands at the gateway ready to offer a home on her wide plains to all who come.

Our consular agent at Corumbá, Mr. C. C. Cooper, in his report for 1903, informs us that the State Government was making arrangements for the introduction of 600 families of Slavonian origin, 300 of which were for settlement on the plateau near the capital, and the remainder in the south of the State.

There are on the river Cuyabá several sugar factories properly equipped with modern machinery, which I am informed have yielded fortunes to their owners. The sugar and white rum which they produce is all consumed locally, and is insufficient in quantity to meet the demand. The soil adjoining the river seems specially adapted for growing sugar-cane, which is stated to yield a crop for fifteen or twenty years in succession without being replanted.

Of far greater importance than agriculture are what may be called the extractive industries carried on in the State; these are the collection of Paraguayan tea, rubber, and ipecacuanha. The forests where the Paraguayan tea or *máte* is collected lie in the south near the Paraguayan frontier. Belonging to the State, they are leased to a firm in Rio de Janeiro which employs a large body of labour, mainly Paraguayan, to collect and prepare for market the leaves of the shrub known as *Ilex Paraguayensis*.

In 1903 the value of the máte exported from the State was £118,000—considerably more than half of all the other exports taken together. Most of this máte is consumed in Argentina and Uruguay, where it still forms the favourite beverage of at least all the lower class of natives.

Rubber is collected in the valleys of the Xingú, Tapajoz, Guaporé, Mamoré, and Madeira, and their numerous tributaries, where there are extensive forests containing trees of the Hevea species. Of recent years the great demand for and high price of rubber, especially the favoured Pará, has led to increased attention being paid to this branch of industry in the State. A large proportion of the rubber is exported through Cuyabá and Sao Luiz de Caçeres on the river Paraguay, where it reaches the river Plate *en route* for Europe, although some is also exported *viá* the Rio Madeira down the Amazon.

The industry is organised on practically the same lines as those obtaining on the Amazon, viz., advances in cash and goods are made by merchants to the owners or lessees of the forest, who in turn make advances to the workmen. The forests are held under title from Government. Large profits are made by those engaged in the industry, but serious losses have also to be faced on account of sickness or death among the cutters, and also through the dishonesty of the latter, who when opportunity offers do not scruple to sell their produce for cash to merchants other than those making the initial advance. So far, I believe, no attempt has been made to cultivate the rubber tree in this its natural habitat. Judging from results obtained in Ceylon and other parts of the East, such an enterprise should prove lucrative, although this is a form of investment

demanding considerable patience on the part of the capitalist, seeing that no return can be expected from the trees for some eight or ten years. Assuming, however, that no natural or artificial substitute for rubber is found, it seems as if the present high prices will be maintained and even exceeded, and a plantation laid out in a tract of forest having a sufficient number of naturally grown trees in working to pay expenses, joined to the cultivation of cocoa, cotton, or other tropical produce, as well as food supplies for the labour, offers, in my opinion, a reasonable prospect of success from a financial point of view. The value of the rubber exported from the State for the years 1901-1903 was, according to our Consular Agent's Report, as follows: — 1901, £32,783; 1902, £37,748; 1903, £41,404 15s. There is an *ad valorem* duty of 23 per cent. payable to the State Government on export. I understand that recently new sections of forest have been opened up, so that for some time to come the output is likely to increase.

Another product of the State is ipecacuanha, or "poaya," as the natives term the well-known drug. Its habitat is in the dense forest bordering the right bank of the river Paraguay and its tributaries, between the 15th and 16th parallels of latitude. The ipecacuanha plant is small, growing only a few inches above the ground; its curious vermiform root contains the active principle—emetine, used in medicine. It is dug up with an iron-shod pointed stick called a *saracua*, dried by exposure in the sun, and baled for market. The industry is financed by the same methods as those I have referred to as being in vogue in connection with rubber. The cultivation of the plant in Johore has, I learn, been attended with success, and the risk which at one time appeared to be probable of a diminished output through the exhaustion of the Matto Grosso forests, has now been obviated, as considerable quantities are now exported from Johore plantations. The value of the root exported from Matto Grosso in 1903 was £5,001 16s., or a little over a third of what had been exported two years previously. There appears no reason why a plantation of ipecacuanha in Matto Grosso should not with proper supervision be a success.

Cattle Raising.

In some parts of the State large herds of cattle are raised, but the distance from market is an obstacle to fuller development of the pastoral industry. Near Sao Luize Caçeres on the Upper Paraguay there is an important Saladeiro, or meat-preserving establishment, owned by a Belgian company, and extract of meat figures among the exports of the State for 1903 to the extent of close on £13,500, showing an increase during two years of over 74 per cent., while for the year under review dried hides to the value of over £40,000 were exported.

Much might be done to improve the breed of cattle by the importation of fresh stock and the subdivision of the vast estates, but at present the same system, or rather lack of it, exists in the majority of cases as existed in the Argentine Republic in the early days.

Mineral Wealth.

No description of the resources of the State would be complete without a reference to its mineral wealth. This is considerable, and, as I have indicated, it was due to the discoveries of gold early in the eighteenth century that Cuyabá was founded in 1719 on the left bank of the river of the same name.

The municipal records, still extant, show that the amount of gold on which a tribute of one-fifth was exacted by the Colonial Government on behalf of the Portuguese Crown was very large, and, as contraband was commonly resorted to where possible, these official data must be taken as under-statements. From an excavation near the capital, tradition has it that over 150,000 ounces of alluvial gold were extracted in a month. Whether this statement can be accepted or not, the old workings are so extensive as to be in themselves evidence of the past importance of the industry, as they can hardly be regarded as representing unremunerative labour. To-day, during the rainy season children may be seen searching for gold in the streets of the capital after a heavy rainfall has effected disintegration of the soil.

Other ancient mining centres are Livramento and Poconé to the west and south-west, and Diamantino to the north, in addition to numerous villages in the north and north-west now completely abandoned. The work was not always confined to the gravel deposits, as in some cases shafts have been sunk on small but rich quartz leaders, from which the gold-bearing rock was extracted, crushed, and panned off in bateias—the name given to the wooden pans still in use in washing gold in Brazil.

Important diamantiferous deposits were also worked at Diamantino some 120 miles north of

the Capital; this town must not be confounded with the better known town of Diamantina in Minas Geraes, where the diamond is also found. The Brazilian diamond is met with under conditions somewhat different from those obtaining in the world-famous Kimberley mines. So far as I am aware the "blue ground" and "volcanic pipe" formation has not been met with in Brazil. Many of the stones occur in river beds associated with auriferous gravels; in this case they are clearly derived from some matrix, the nature of which appears to be somewhat obscure. According to the geologists Derby and Gorceiz, who have made a special study of the question, the Brazilian diamond is also met with in a schistose granular quartzite of a flexible kind known as Itacolumite, a mineral which takes its name from a range of mountains near Ouro Preto in Minas Geraes, but this also may be a secondary formation.

The French traveller, Castelnau, who explored Matto Grosso in 1843-44, states that sandstones occur in the vicinity of the workings near Diamantino, and from these he supposed the diamonds to be derived. Some years ago a rich find was made near Diamantino, stones to the value of £20,000 having been taken out in a short time.

Present Position of Mining.

Mining operations both for gold and diamonds have declined in importance since an epidemic of small-pox swept the State in 1867, and since the abolition of slavery. Until recently they were limited to the work carried on by individual native prospectors. As the result of these, small parcels of gold-dust and diamonds are still occasionally acquired by local merchants. In 1902, however, a company known as the "Transpacific Gold-mining Company," was formed at Charters Towers, Queensland, with the object of dredging the river Coxipo d'Ouro for gold, under a concession granted by the State Government.

This stream, which rises on the plateau to the north-east of the capital, falls into the river Cuyabá on its left bank about a league below the capital. A dredge was constructed by a well-known New Zealand firm, and although it capsized during a flood, it is now, I understand, again at work and yielding satisfactory returns, a recent return showing thirty ounces of gold for a run of fifty-three hours. During the operations small diamonds have also been recovered.

Consular-Agent Cooper reports that other rivers in Matto Grosso have lately been prospected, and that new syndicates have been formed on the strength of the favourable reports received. Mr. Cooper also states that he has no doubt a great many of the rivers are rich enough to be profitably dredged, and that capitalists are commencing to recognise the fact. I have learnt only recently that reefs near the capital are also now being examined on behalf of English capitalists, so that it is not improbable that at no distant date the gold and diamond mining industry, which did so much for the State in the past, may be revived.

Manganese and Other Minerals.

An extensive deposit of manganese exists in the mountains of Urucum and Morro Grande, a few miles south of Corumbá, at a height of over a thousand feet above the level of the river Paraguay. Mr. Consul Cooper refers to it in the report which I have already quoted. The mode of occurrence of the deposit is such as to render extraction comparatively easy, while the height above water level would ensure immunity from water as a disturbing factor in working, and at the same time make the construction of an aerial cable-way to the river Paraguay easy. If a railway were found more convenient, I believe that sufficient electrical power could be generated to operate it from a stream which rises in the mountains where the deposit exists. From the railway terminus it would be necessary to ship the mineral in barges to Rosario on the river Paraná (a distance of over 1,400 miles) where it could be transhipped to ocean-going steamers. This question of trans-shipment has probably hitherto proved the main obstacle to the working of the deposits, but the whole question appears to be one worthy of attention on the part of those interested. In other parts of Brazil manganese deposits are being successfully exploited on a large scale, and much of the ore is of excellent quality.

Copper is stated to exist on the River Jauru, between Saõ Luiz de Caçeres and the old city of Matto Grosso. Platinum is also reported to have been discovered near Diamantino, probably in auriferous gravels, while deposits of high-grade iron ore, close to those of manganese, near Corumbá, are practically inexhaustible.

Mining Laws.

The mining laws of the State are liberal, both as regards the area granted for explor-

ation, and also as regards the conditions of working.

By the Constitution of the Republic, the minerals are declared to belong to the owner of the soil, or in the case of public land, to the State. At present each State has its own mining code. In Matto Grosso, concessions to work mineral deposits are preceded by an exploration right; under this, one may obtain the right of prospecting any area up to 280 square miles in extent, on depositing a sum of about £250 with the Government. This sum becomes forfeited if operations are not begun within two years. On completion of the preliminary operations the concession to work is made—usually for thirty years. Under this one hundred and fifty claims of about 170 acres each may be pegged out. The royalties charged are insignificant, but there appears to be no guarantee that a heavy export duty on the product may not be exacted.

Commerce.

The commerce of the State is slowly but surely developing. Mr. Cooper, however, considers that if the United Kingdom does not participate more fully it is solely due to the action of manufacturers here, who content themselves with forwarding catalogues printed in English, whilst our Continental competitors have theirs translated into Portuguese and Spanish, appoint active agents at Corumbá and Cuyabá, and periodically send out competent representatives to visit old clients and form new connections.

Further, German, French, and North-American traders give longer credit to desirable firms than ours do, and whilst a large majority of local merchants would doubtless prefer to deal with British firms, they are unable to do so owing to the hard-and-fast conditions offered, and to the want of sufficient information regarding our manufactures.

Mr. Cooper's complaint as to catalogues being printed in English is one with which the public has become familiarised through reading consular reports from almost every part of the world, and adds another proof, were one needed, of the lack of initiative which still appears to characterise a large section of our commercial community.

The total exports from the State during the year 1903, calculated at the exchange of 1s. per milreis, amounted to £219,322 13s. Deducting the value of máte, or Paraguayan tea, exported to neighbouring republics, £118,000, there is a balance of £101,322 13s.. made up principally of rubber, hides, and extract of meat.

From the official returns it is impossible to determine what proportion of this latter sum represents the exports to the United Kingdom, as the exports to Europe (nearly £73,000) are entered as being shipped to Monte Video in transit. Germany and France take a certain proportion, but the greater part goes to the United Kingdom.

The imports for the same period amounted to £247,313. Of this sum about 55 per cent. represents imports from other Brazilian States, and while nearly £14,000 are entered as the value of imports from the United Kingdom, this latter figure does not represent the total, owing to the goods shipped out of bond from Monte Video, and those "in transit" from Europe introduced into the State without proper classification, being entered as imports from Uruguay. Our exports to the State comprise:—Hardware, machinery, tools, drugs, woollen and cotton goods, paints, oils, cutlery, wire for fences, ironmongery, gunpowder, sewing machines, printed goods, &c.

Banking facilities do not now exist at either Corumbá or Cuyabá since the Banço Rio and Matto Grosso went into liquidation. This state of affairs tends seriously to hamper commercial transactions, the importance of which justifies the establishment of an agency of one of the Rio banks in the opinion of our Consular representative.

Political Constitution.

As a constituent part of the Federal Government of Brazil, Matto Grosso now manages its own internal affairs, electing its own Governor or President, and having its own local legislature and judicature, besides sending representatives to the Federal Congress. In the time of the Empire the Governor was nominated by the Central Government, which appears to have done little towards advancing the interests of a province considered too remote to be of much importance. As showing the ignorance at one time prevalent in Rio regarding the conditions of life in Cuyabá, a resident of the latter was gravely asked by a citizen of Rio if it were true that jaguars roamed the streets of the former city.

Principal Towns.

Cuyabá, with a population of about 15,000, is the largest city in the State. Here is the residence of the Governor, the Legislature, and the various Government offices, including a war arsenal and military barracks. The

city covers a large area, as nearly all the houses have extensive compounds or yards attached to them. Most of the houses are of adobé, with tiled roofs. The streets are paved with blocks of quartz, undoubtedly extracted by the pioneer miners who founded the city. There is a service of tramcars from the port on the river to the city proper, and Cuyabá can boast of what many a town nearer the littoral cannot, viz., a proper water supply, derived from the river by pumping to a reservoir on an elevated site.

Next in importance is Corumbá, situated on the river Paraguay, and distant from the Capital about 440 miles to the south. It is the seat of the principal Custom-house of the State, and, in addition, is the point where goods in transit for Bolivia are cleared. Close to Corumbá is the naval arsenal of Ladario, founded after the conclusion of the Paraguayan war.

Saõ Luiz de Caçeres is also of some importance on account of its exports of rubber and ipecacuanha.

Villa Bella, also known as the City of Matto Grosso, is situated on the river Guaporé, and until 1820 was Capital of the province, but it had to be abandoned on account of its unhealthiness. It is now in a state of decay, and the former palace of the Colonial Governors and other public buildings are falling into a state of ruin. A few years ago I was informed that there were only a few inhabitants, and that at night the streets were unsafe on account of the incursions of the Indian tribes from the adjacent forests.

The Future Prospects of the Country.

Endowed with great natural resources, there can be no doubt that in a future, not perhaps remote, Matto Grosso is destined to become a great and wealthy State. To achieve her destiny she stands in need (probably more than any other State of Brazil) of capital and labour. To attract this should be the aim of those charged with the administration, and one can only wish success to the recent efforts of the Government directed towards the formation of agricultural colonies, and hope that the various projects for improving the means of communication and developing the mineral resources of the country may be realised.

It is sometimes said that the twentieth century will be one of marked progress for South America. If this prediction be fulfilled, let us hope that Matto Grosso may share in the general prosperity.

DISCUSSION.

Sir Martin Conway thought the members were extremely indebted to the author for the admirable manner in which he had put together so much information, partly from his own observation and partly from information derived from the best authorities. What always struck him about South America, not only about the particular district under discussion, but about many other parts of the country, was the universal report obtained from everybody who visited that part of the world, and made himself at all intimately acquainted with it, of the great natural wealth of those regions. On the other hand, the general trend of the energies of energetic people was towards quite different regions of the world, which were not so obviously rich, and did not present the same natural advantages for rapid development as the attractive and wealthy continent of South America. He believed the time would sooner or later come when more attention would be devoted to South America. It might very well be that in the future the twentieth century would be remembered as the period in history that efficiently discovered that continent. To him South America was chiefly interesting as essentially the continent of romance. There was no other part of the world where so much romance was left. The moment a traveller landed in South America he found himself in a country where nothing was done as he was accustomed to seeing it done elsewhere. The people preserved a character of their own, which they did not show the smallest tendency to file down and mould into the recognised form of the Western world; on the contrary, they had a faculty, which he was delighted to observe, of turning the newcomer very rapidly into one of themselves. He, therefore, had good hopes that South America would never become, even in the future, the kind of smug, Philistine, law and order, cold bath, honest behaviour continent which people were accustomed to regard as the ideal of the future. On the contrary, he hoped South America would long continue a region of moderate law and order, a place where things might happen unexpectedly, where what happened one day would not necessarily happen the next, which was not entirely thatched with newspapers, and a place where advertising did not pay. Generally speaking, South America was a most delightful, friendly, happy and romantic continent, a place where a man could go and really have a holiday. He therefore looked forward to the twentieth century, when it made full acquaintance with South America, bringing back into the Old World a sort of breeze of freshness and a new spirit of adventure and of life which had passed out of it.

Dr. J. W. Evans congratulated the Society upon having a paper on the subject of Matto Grosso by one who was perhaps more qualified than any of his countrymen to speak on the subject, because he had lived longer in the place, and had more oppor-

tunities of studying the characteristics and capacities of the country. When he (the speaker) visited Matto Grosso ten or twelve years ago he had the good fortnne to meet with the author, and would always remember with pleasure their adventures together in the forests and in the wonderful plains of that mighty region. The climate in the upper regions was of a very invigorating character, it being quite as cold at night as in this country. Every farmhouse in that part of the world had a special room set apart for travellers. In the centre of each side of the room was a hook, to which the hammocks of the travellers were slung, so that five people could be accommodated in each room. It was on the high plateau to which the author had referred that he first made the acquaintance of the carts used in the country, being startled about 4 o'clock in the morning by what he thought was the squeaking of a drove of pigs. He hoped in the near future the country would be opened out; with so vast and beautiful a country there was no fear that Matto Grosso would ever cease to be a country of adventure and magnificence to the wayfarer.

Senhor CHERMONT (Secretary of the Brazilian Embassy to the United States) congratulated the author, on the part of his countrymen, on the excellent paper he had read, and expressed the hope that the Chairman, who probably knew more about the country than anybody else, would give an interesting contribution to the discussion.

The CHAIRMAN said the author had referred to the resources of that wonderful land in the interior of Brazil, which might be called the heart of the country, and had in no way drawn on his imagination. Anyone who had visited Matto Grosso must discover in it a wealth of agricultural possibilities, and perhaps one of the great Eldorados of the world. Ever since he was a boy he had heard of the riches of Cuyabá and its vicinity. The ground was highly mineralised in all directions, and he believed it had only been scratched by the old Portuguese miners, despite the number of years they had worked there. The reason why Matto Grosso lay fallow to-day was because of its inaccessibility. Once the problem of easy communication was solved, he ventured to assert that it would become one of the richest, most prosperous, and most productive parts of the Republic of Brazil. Southern Matto Grosso was first crossed by Alexio Garcia, a Portuguese adventurer, who was landed by one of the Spanish expeditions upon the coast of Santa Catherina. He lived for many years among the Indians, and then, working his way inland, organised an expedition to the north of Paraguay, which passed through the Tupi-Guarani tribe and its offshoots; and proceeded to cross the Grand Chaco of Southern Bolivia, and raid the empire of the Incas. That was prior to the time of the celebrated contract in the Bay of Panama between Pizarro, Almagro and Luque for the discovery and conquest of the Inca Empire; he preceded Pizarro's forces by at least four years, and he wished more credit could be given to the brave and daring adventurer. On his return, he fought his way back to the upper waters of the Paraguay, and was there killed by the Indians. He was loaded at the time with gold and silver, which he captured upon the slopes of the mountains before he reached the plateau. A little later than that Senhor Correa crossed the northern part of Matto Grosso, after which a long period of time elapsed until about 1719 or 1720 a Portuguese named Sutil discovered gold in the vicinity of Cuyabá. In 1723, such had been the development in the gold diggings, and such the prodigious quantities of King's Fifths paid at Sao Paulo, that a gold fever took possession of nearly all the people of Sao Paulo, and there was a rush for the diggings. The route they took was that taken by the slave hunters, the Mamalucos, who were half-breed Indians and Portuguese. They crossed the coast range at about 3,000 feet elevation, descended the Tieté river, reached the Paraná which they descended about 100 miles; then went up the river Pardo, and crossed over into the Jaquary river, which entered the Paraguay river, and up the Paraguay to Cuyabá. Many of those expeditions were almost annihilated by the savages in taking revenge for the bad treatment they had received at the hands of the Mamalucos. Later on, when the fame of the gold discoveries became known, many efforts were made to reach Cuyabá and southern Matto Grosso. The first route taken was by way of the Guaporé river, which separates Bolivia from Brazil, an expedition going down that river in 1742 into the Madeira, and then to Para. In 1746, Captain Souza crossed from Cuyabá over to the head waters of the Tapajoz river, descended it, and reached Pará, returning in 1747 by way of the river Madeira and Guaporé, taking a load of goods with him. The reaching of Matto Grosso by the Amazon side was practically out of the question for commercial purposes, the cost of transportation being so great. For instance, in the Xinjú River, lying east of the Tapajoz, there were no less than 400 miles of rapids and cataracts. While the Tapajoz was not so completely interrupted by rapids and falls, it was full of them, and at such intervals that it was a great hardship to undertake its navigation. Considering that the Tapajoz was 1,200 miles long, it would be considered a very large river in the Old World. There was now a prospect of a railway being built round the great bend of the Madeira to avoid its falls and rapids, there being no less than nineteen in a distance of 263 miles, among which he was wrecked in 1872. By a treaty made in 1903 between Brazil and Bolivia over the Acre question, Brazil undertook to build a railway about 200 miles long to avoid these falls; and as it at present costs £80 per ton to carry goods past them, it would be easily understood that the price would be materially reduced when the railway

was built. At the upper terminus of the railway, and concentrating upon it like the wings of a fan, were no less than 3,000 miles of magnificent navigable streams, many of which could be navigated all the year round by craft which drew six feet of water. Whether Brazil could reach Matto Grosso and Cuyubá by that route without spending considerable sums of money in clearing out the obstructions which existed in the Guaporé was, to his mind, a question, but it was possible that might be a very excellent route for the development of western Matto Grosso. Turning to the plateau side, Cuyubá could be reached with 18 inches of water at some seasons of the year, and at others with a little greater draught, but the change of freights at different points on the river made it rather an expensive method of communication for goods. Personally, he believed Matto Grosso would be reached in quite a different direction. He discussed the subject with Dom Pedro II. in 1889, a few months before the fall of the Empire; in fact, Dom Pedro entrusted him with the carrying out of the enterprise. It was not done, as the Empire fell a few months afterwards. South-west of Rio Janeiro there was a bend, and almost at the farthest western point it there was the beautiful bay of San Francisco; and, if from there the old route of the Mamaluco raiders were taken, it would be about the shortest cut to the headwaters of the Paraguay and Cuyabá rivers, and would open the country as Brazil deserved to be opened. He thought it might be said of Brazil that until it changed its policy of developing nothing but its Atlantic fringe it would never be the great country it ought to be. At the present time countries which desired interior development extended their railways far inland, which was the case in Canada, the United States, the Argentine Republic, India, and China; and once Brazil threw one or two main lines of railway into the country from the Atlantic coast, its development would be something enormous. That referred more especially to the line he had indicated, because it would tap the marvellously rich resources of Bolivia, than which he did not believe any other region possessed equal ones; it would tap Paraguay, and would be a grand trunk line for a commerce with the States which must now necessarily lie dormant until such a line is built. The author had referred to the low elevation of Corumbá—288 feet. When it was remembered that Cuyubá, according to the observations of Clauss, was only 660 feet above the sea and 2,000 miles up the river, it gave one an idea of the very little fall there must be in the great Paraguay and Paraná rivers. It was exactly the same with the Amazon. He believed that the 2,500 miles up the Amazon, up to the frontier of Peru, the elevation was not 200 feet. The whole of the region of Central South America was very low, with the exception of North-east Bolivia, which lay on a shelf about 500 or 600 feet above the lower country. Matto Grosso was nothing but the western extension of a vast sandstone plain resting on shales, which again rested on metamorphic rocks, and the country, contrary to the general idea of geographers, did not slope from the Andes to the Atlantic, but the other way. It bore out the fact, which he thought must now be accepted, that the whole of Brazil was separated from the Andean region by a vast inland water communication of lakes and great gulfs. Brazil was interesting from every direction in which it was analysed. Without wishing to go outside the limits of the paper, he had simply desired to make a few remarks to impress upon the audience how the world might reach the vast resources of Matto Grosso. It only remained for him, in conclusion, to move a cordial vote of thanks to the author for his excellent and comprehensive paper.

The resolution of thanks having been carried unanimously.

Mr. MILNE, in reply, said that whatever value his paper had it had been considerably enhanced by the Chairman's remarks.

STATISTICAL ABSTRACT OF THE BRITISH EMPIRE.

The Board of Trade has just issued the first number of the "Statistical Abstract of the British Empire." It is intended to meet the growing demand for statistical information as to the trade, shipping, and production of the Empire, and especially as to the trade relations both between the Empire and foreign countries, and also among its various constituent parts. It is a most convenient compilation. A good deal of its information has already appeared in more formidable volumes, but here it is found in handier form with not a little that is new. It is hoped that in future numbers the information given, more especially in the section dealing with production, will be still more complete, and that it may be possible to add further sections dealing with other kindred subjects. As a general rule, the comparative tables relate to a period of years ending 1903, but certain Tables that have to be compiled from the trade returns of the various colonies and possessions refer to 1902.

Our smallest possession in one sense is our greatest in another, Gibraltar, the first of fortresses, having an area of only 1⅞ square miles. Bermuda comes next with 19 square miles. The area of the Empire is 9,631,000 square miles, and in 1901 it had a population, all told, of 360,646,000, of which 41,458,721 were in the United Kingdom, and 294,361,056 in India, including the Native States. In the twenty years 1881-1901 the population of the Empire increased by 57,460,000.

The growth or decrease in our trade with the principal countries of the world, taking the figures for the six years 1898-1993, are shown in the following Table,

which gives our imports from and exports to the countries named:—

Country.	Year.	Imports.	Exports.
		£	£
Russia ..	1898	20,995,452	16,781,574
	1903	32,871,707	17,783,160
Denmark	1898	11,758,910	3 960,236
	1903	16,829,970	4,750,068
Germany	1898	39,106,992	55,647,400
	1903	45,917,366	57,521,904
Belgium	1898	26,194,527	20,138,829
	1903	33,038,097	20,697,517
France..	1898	59,770,422	35,627,658
	1903	54,003,496	39,121,295
United States.	1898	164,551,814	65,644,155
	1903	178,715,386	79,369,929
Japan ..	1898	5,073,543	12,842,148
	1903	4,709,254	11,752,284

It will be seen that the only country whose imports and exports from and to us show decrease is Japan, and the only other country which shows a decrease is France, whose imports to us have fallen in the six years nearly six millions, almost all of which has occurred in the last three years, our imports from France for 1900 being £59,271,732.

The increase in the trade of India and the Colonies with foreign countries has been great during the last fifteen years. The Australian imports have increased from £6,602,000 in 1889 to £12,975,000 in 1903; that is they have nearly doubled. The imports of the Dominion of Canada have in the same period increased from £14,535,000 to £36,138,000; those of India from £10,214,000 to £20,771,000; even the West Indian Islands have increased their imports from £2,584,000 to £3,087,000. So with the exports, taking the same fifteen years to 1903. In 1889 the Australian exports to all foreign countries (including bullion and specie) were valued at £4,554,000 in 1903, they had risen to £12,716,000. In the same period the exports from the Dominion of Canada had increased from £9,690,000 to £17,241,000. The West Indian Islands show a slight decline—from £3,714 000 to £3,433,000—whilst the exports from India have increased from £32,377,000 to £60,258,000. The exports from the Cape of Good Hope, which include the value of goods sent from the Transvaal, Orange River Colony, and Basutoland, for shipment at South African ports for foreign countries, and include also "Ships Stores," classed with foreign countries in the original trade returns, increased from £479,000 to £3,078,600. The exports of Natal increased from £95,000 in 1889 to £612,300 in 1903.

If we turn to the trade between the United Kingdom and other parts of the British Empire, it will be found that between 1889 and 1903, our imports of animals, living, for food, were increased from £1,629,923 to £3,483,253; of meat of all sorts from £2,442,279 to £8,026,814; of butter from £175,490 to £2,697,536; of cheese from £1,583,216 to £4,991,186; of wheat, from £5,129,084 to £10,658,472; of fruit, from £464,964 to £1,656,707; of tea, from £6,458,406 to £8,364,007; of tin in blocks, from £2,698,622 to £4,198,234. But our imports of rice have fallen from £1,842,981 to £1,454,284; of raw sugar from £3,283,630 to £622,315, of refined from £6,698 to £437; of wool, raw, from £24,009,645 to £18,297,546. Our exports do not show unvarying increases. Exports of cotton manufactures have fallen from £2,685,827 to £1,537,364; of haberdashery, from £1,708,456 to £1,706,354; of coal, from £1,996,811 to £1,816,286; but woollen tissues show a slight improvement, apparel and slops have increased from £4,025,650 to £5,637,947; and all kinds of iron and steel show increases, especially machinery and mill work, from £4,263,177 to £7,970,400.

Turning to production, and commencing with gold, the United Kingdom produced 3,890 ozs. in 1889 and 5,495 ozs. in 1903. Australia shows a large increase, from 1,542,550 ozs. to 4,563,596 ozs., Western Australia constituting by far the larger portion of the increase—from 15,493 ozs. in 1889 to 2,436,311 in 1903. New Zealand increased her output from 203,211 ozs. to 533,314 ozs.. The figures for the Transvaal are not given earlier than for 1901, but the Dominion of Canada shows a large increase, from 62,658 ozs. in 1889 to 1,032,253 ozs. in 1902. Even British Guiana shows an improvement, from 20,216 ozs. to 104,525 ozs. The figures relating to wheat production are very striking. The production of the United Kingdom has fallen from 75,883,611 bushels in 1889 to 48,818,788 bushels in 1903. On the other hand, India produced 256,704,000 bushels in 1890, and 357,162,139 in 1903. The Australian production was very unequal, being 34,039,289 bushels in 1889 and 74,149,634 in 1903, but in 1895 it fell to 18,270,348 bushels, and in 1902 was only 12,378,068. The quantity of coal produced in the United Kingdom has risen from 176,916,724 tons in 1889 to 230,334,469 tons in 1903. In India the output has increased from 1,946,172 cwts. to 7,438,386 tons; in Australia, from 3,976,035 tons to 7,112,078 tons; in the Dominion of Canada, from 2,373,485 tons to 7,139,852 tons. The iron ore produced in the United Kingdem shows some decrease, from 14,546,000 tons to 13,716,000 tons; but the output of pig iron is a little larger, rising from 8,322,824 tons to 8,935,063 tons. Wine comes almost entirely from Australia and the Cape of Good Hope. The Australian output has risen from 3,567,025 gallons in 1893 to 6,159,169 in 1903; but the Cape output which was 5,646,426 gallons in 1889, was slightly less in 1903—5,332,349 gallons. Tea, coming from British India, Ceylon, and Natal, has increased from 141,133,984 lbs. to 361,927,067 lbs., the increase in Natal being from 43,024 lbs. to 1,761,091 lbs. Coffee shows a considerable decrease, from 49,306,636 lbs. to 38,356,801 lbs., largely owing to Ceylon having turned to tea, the Ceylon production having shrunk from 9,865,184 lbs. in 1889 to

1,104,544 lbs. in 1903. Sugar too shows decrease, from 54,700,000 cwts. in 1898 to 50,000,000 cwts. approximately in 1903.

It is regrettable to find that the production of cotton has made very little headway. The total production within the Empire in 1889 was 1,178,652,000 lbs., of which British India contributed 1,173,060,840. In 1903 it had risen to 1,314,103,000 lbs., of which British India produced no less than 1,312,474,000 lbs. Fiji has ceased to grow it, the production of Malta has fallen from 1 350,608 lbs. to 416,752 lbs., that of Cyprus from 3,070,208 lbs. to 337,120 lbs., that of Lagos from 489,950 lbs. to 289,841 lbs., that of Ceylon from 209,187 lbs. to 151,704 lbs. The West Indian Islands are trying to grow a little, but Grenada, which at one time promised to grow a good deal, has fallen away from 375,984 lbs. to 301,010 lbs.

The second part of the statement deals with shipping. In 1889 the tonnage of sailing and steam vessels on the register in each part of the British Empire was 9,471,553 tons, in 1903 it had risen to 11,831,439 tons. But there has been steady decreases in the tonnage of sailing vessels. In 1889 it stood at 4,412,824 tons, in 1903 it had fallen to 2,802,053 tons. On the other hand steam tonnage has risen from 5,058,729 tons in 1889 to 9,029,386 tons in 1903. Nearly all the Colonies show some increase with the exception of the Dominion of Canada, whose tonnage has fallen from 1,022,737 in 1891 to 681,646 tons in 1903; but the decrease has been entirely in sailing ships, Canadian steam tonnage having increased from 113,836 tons to 205,123 tons. If the shipping entered at principal ports in the British Empire is taken, the figures show that London remains far ahead of any other port. In 1888 the shipping entered at the port of London amounted to 7,470,949 tons, in 1902 it had increased to 10,179,023 tons. The next in importance is Liverpool with 6,843,200 tons in 1902, and then Cardiff with 4,688,088 tons, the Tyne ports, namely Newcastle, North and South Shields, and Blyth, coming very near with 4,485,810 tons. Glasgow attracted no more than 1,618,663 tons. Of Colonial ports Hong Kong ranks first with no less than 8,253,591 tons, then follows Singapore with 5,431,530 tons, Colombo with 4,574,271 tons, Sydney with 3,283,399 tons, and Melbourne with 3,157,524 tons. In shipping cleared in the United Kingdom, London was first in 1888 with 5,470,912, Cardiff coming second with 5,148,068 tons, Liverpool third with 4,941,556 tons, and the Tyne ports fourth with 4,392,727 tons. But in 1902 the relative positions were changed. Cardiff, among home ports, stood first with 7,868,556 tons, London second with 7,385,085 tons, Liverpool remained third with 6,314,514 tons, and the Tyne ports fourth with 6,208,812 tons. As with shipping entered, Hong Kong stood first among Colonial ports with shipping cleared with 8,217,621 tons, or nearly half-a-million tons in excess of Cardiff, and nearly a million tons ahead of London.

AUSTRALIAN TRAMWAY SYSTEMS.*

In no part of the world, in proportion to the number of population, are street tramways more extensively used as a means of passenger transit than in the leading Australian State capitals. Although their introduction is of comparatively recent date, their development has been marvellous, and, as in many European and American cities, they have assisted in making riding cheaper than walking, and are causing the omnibuses and other conveyances of a past generation to become forgotten. In Sydney the tramways were originally worked by steam power, the cars being double-decked, like the railway carriages on several of the Paris suburban lines, but subsequently the cable system was introduced, and later on electricity became utilised as a motive power, and with such success that it is only a question of time when the locomotive and cable will be found dispensed with. The various tram-lines, which, like the railways, are the property of the State, form a complete network of communication between nearly every part of Sydney and its suburbs, thus assisting in counteracting the tendency to overcrowding which forms one of the evils associated with large centres of population. The total length of tram-lines open on June 30th, 1903, was 124½ miles, representing an expenditure of £3,371,587 for construction and equipment, the number of passengers carried during 1903 being 130,405,402. The Melbourne system, embracing a length of 48 miles, 43½ miles of which are worked by cable, and 4½ miles by horse-power, was constructed by a municipal trust at a cost of £1,705,794, and is leased to a company. It is said to be the largest and best cable system in existence. The number of passengers carried during the year was 47,564,942. There are also several suburban lines worked by limited liability companies as follows:—horse 8½ miles, electricity 4 miles, and cable 2¼ miles. In Brisbane the tram-lines were originally worked by horse-power, but in 1897 it became replaced by electricity, the tramways being the property of an English company, and covering a total length of 28 miles. As the traffic increases, extensions are effected. At the close of 1902 there were in the State 65 miles of tramways, including those in Brisbane, the number of passengers carried during 1903 being 18,125,302. In Adelaide there are several tramway lines worked by horse-power, but an attempt is being made to secure the introduction of the electric system. The lines are owned by private companies. In Western Australia, Perth has a well-organised system of electric tramways, which, like that in the Kalgoorlie Municipalities, is the property of a private company. Freemantle and Boulder City also will shortly be in possession of electric tramway systems, constructed by private enterprise under municipal supervision. The only state-owned tramway is that running between the

* Contributed by Mr. John Plummer, Sydney, New South Wales.

port of Roebourne and the town of Cossack, a distance of 8½ miles, in the north-western portion of the State. In Tasmania, the Hobart tramways are worked by electricity, and extend a distance of about 9 miles. They are owned by a private company, and were opened in 1901, in which year they carried 1,432,176 passengers. There is also a steam tramway in the north-west portion of the State, connecting Zeehan with Williamsford, a distance of 11 miles, its summit being 1,500 feet above sea level. Compared with other Australian tramway systems, that of Sydney is considerably the most efficient, there being a conspicuous succession of trams from early morning until midnight, an all-night service being established on several lines. During the earlier hours of the day and in the evening the tram traffic is enormous, the cars running almost every minute, being densely crowded. It is the same at holiday time, and the greater the amount of accommodation provided by the State Railway Commissioners the denser becomes the crowding. It is as if the whole population desired the use of the tramcars. Yet, with all this heavy traffic, accidents are comparatively few, being in most instances due to the disregerd of ordinary precautions on the part of the sufferers. All the Australian electric systems are on the overhead wire principle, which is not found to interfere with the work of fire brigades to anything like the extent originally anticipated. The cost of the New South Wales tramways was defrayed out of loan revenue, and they constitute one of the most valuable assets of the State.

THE VEGETABLE PRODUCTS OF THE EAST AFRICA PROTECTORATE.

East Africa has yet no predominating leading products of the vegetable kingdom, that is to say, its exports are made up of a great variety of products, no one of which can be definitely said to predominate, and the settlers do not yet seem to be quite certain as to which product will be the staple of the country. Potatoes at one time threatened to absorb the attention of the majority, and in the year 1903, 938 tons were despatched from the vicinity of Nairobi, which is the natural centre of this industry. The Assistant-Deputy Commissioner for the East African Protectorate, in an interesting report recently received from him says that unfortunately numbers of the potato growers lost heavily in their attempts to exploit the South African market, not through any fault in the tuber itself, but owing to the export trade being spoiled through bad handling, careless selection, and a general lack of experience in the business both on the part of the growers and their agents. The total export of potatoes has increased from £300 in value to, roughly £3,000. Great attention is being paid to the cultivation of cotton. Efforts, however, have not advanced much beyond the experimental stage. The best cotton crops are believed to be those at the Indian settlement at Kibos, where some 75 acres are under cultivation. A quantity of seed has also been distributed among the Kavirondo chiefs, and the crops look very promising. Several settlers in the direction of Fort Hall have tried patches which promise well, and fairly good samples have been grown in Kikuyu and around Nairobi. These samples were examined by the British Cotton-growing Association, and priced at 5½d. to 6d. per pound. The seed was Egyptian. The castor oil plant exists in a wild state over a great part of East Africa, and its cultivation should, therefore, prove easy. The seed is worth £8 to £9 10s. per ton. There is a fairly large local market for the oil, owing to the demands of the railway. There are large areas between Voi and Makindu where Sanseveira and aloe fibre are to be found in a wild state. A European firm has lately taken a lease of land near Kibwezi for the purpose of working them. An American firm has taken up an area for the same purpose on the river Tana, and is proposing to invest a considerable amount of capital in the undertaking. The fibre, properly prepared, is quoted at nearly £30 per ton. Among those who have any knowledge of Rhea fibre, the general opinion is that it will flourish in the Protectorate. One planter has grown a considerable quantity near Nairobi, and is now offering cuttings and plants for sale. It is a quick-growing plant, and it should not take long to prove its success on a large scale. The processes of decortication, cleaning, and bleaching, however, are said to require considerable outlay in machinery. Sisal hemp is a product of the aloe family, and it appears to grow well round Nairobi and in other localities. It is easily grown, easy to prepare, and the cleaned fibre commands a good price. Mauritius hemp has also been proved to grow well. It will flourish on almost any soil, and is easy to prepare. Ground nuts are being grown by the natives in various parts of the country with great success. The price of this product is, however, low, and a settler wishing to grow nuts at a profit must, therefore, cultivate them on a large scale, using machinery as much as possible. The only enemy of the ground nut appears to be a burrowing mole which eats the nuts before they reach maturity. Both wheat and barley grow well in any part of Kikuyu, and also on the Nandi and Lumbwa plateau. There is a considerable local demand for wheat, and there is said to be no reason, given a sufficient supply to pay for local milling, why local flour should not supply the whole of the east coast, both the Protectorates and Zanzibar. There is an extensive market for a good class o maize in South Africa, and many of the settlers in East Africa have considerable areas of South African and American seed under cultivation. The long red native bean of Kikuya and Kavirondo is in great request in Europe and South Africa, and attention is being devoted to its cultivation. Tobacco grows luxuriantly in Kikuya, Nandi, Lumbwa, and Kair-

rondo, and is largely used by the tribes inhabiting these places. So much, however, hinges on the expert curing of the leaf that it is impossible to say whether the native plant has any commercial value. Sugar-cane flourishes in Kikuya and Nandi, but it is not expected that the country will be able to do more than produce enough for local consumption. In coffee, experiments up to date have been fairly successful, but the present output cannot be considered as being on a commercial scale. What has been produced has been formerly reported upon. The growing of English fruits is being carried on with some success near Machakos, and there is an increasing market for fruit along the line of the railway. Experiments in sericulture have been conducted during the past two years in the Kenya Province. Several hundred mulberry trees of the Japanese variety have been raised. They are evergreen, and produce three or four good crops of leaves per annum. Silkworm's eggs have been introduced from France, and the worms have flourished exceedingly, the mortality in rearing being only one per cent. The silk produced has not yet been valued.

UNITED STATES RAILWAYS.

The report on United States railways, drawn up by the Hon. Robert Collier, Third Secretary to His Majesty's Embassy at Washington, and recently issued (Cd. 2237), contains a specially interesting review of American railway affairs. On June 30, 1903, the latest date for which returns are available, the total railway mileage in the United States was 207,977, and of this more than a third lies in the territory nearest the Great Lakes, bounded on the south by the Potomac and Ohio, and on the west by the Mississippi. The area of this territory is roughly a seventh of the total area of the United States (excluding Alaska), but half the population are found there, while 16 out of the 21 largest cities are within it, and three more on its borders. The capital invested in the railways of the United States in 1903 had reached a total of £2,624,997,970, 51·14 per cent. of which was funded debt. In the same year dividends at the average rate of 5·70 per cent. were paid on 56·06 per cent. of the stock invested. The gross earnings of all the railways amounted to £396,009,772, and over 70 per cent. of this revenue came from the goods traffic. Except in the extreme north-east, and the far west, the passenger revenue is nowhere more than 24 per cent., nor the goods revenue less than 70 per cent., of the total earnings. The total working expenses were £261,987,261, about 21 per cent. of which was devoted to the upkeep of the road and works, 19 per cent. to the upkeep of rolling stock, 56 per cent. to traffic expenses, and rather less than 4 per cent. to general expenses.

Railway servants are paid more wages than in this country, but the cost of living is a good deal higher. In 1903 there were 1,312,537 railway officials and servants of all classes—639 for each 100 miles of line. The increase during the last few years has been remarkable. In 1897 the total number employed was only 823,476, or 449 for each 100 miles. The highest paid class of railway servants are the train men. The average wages of a driver appear to be about 16s. a day, of a train conductor, 13s., and of a fireman, 9s., but as these men are paid according to distance, and not by the day, it is difficult to arrive at a very exact estimate. Station men ordinarily receive from 6s. 6d. to 7s. 6d. a day, signalmen and gangers about 7s.; plate-layers about 5s., and fitters and artisans employed in the shops 7s. to 9s. 6d. Not much has been done towards helping railway servants to secure dwellings, and only a few railways have established funds for providing their servants with sick pay, or with old-age pensions.

Each of the States of the Union imposes taxes upon the railways within its territory, and the Federal Government also receive a small duty. The different States levy taxes on the railways in different ways. For the year ended June 30th, 1902, the total amount of taxes paid by the railways was £11,346,966, of which only £300,647 was paid to the Federal Government. Much the greater proportion of this revenue is raised by taxes based on the value of the whole of the property of each railway, which is arrived at either by direct valuation, or, indirectly, by the valuation of the stocks and bonds, or some analogous method. In the year mentioned all the States raised the whole, or part of the taxes levied on the railways within their borders upon values arrived at by direct valuation, the sum thus received amounting to £7,778,473, and the present tendency is towards using this method more and more. Many States supplemented this by taxes levied on values arrived at by indirect valuation, and by specific taxes upon railway shares, upon gross or net earnings or dividends, or upon traffic.

There is no uniform scale for the whole country by which passengers' fares are determined. Much depends upon the maximum charges permitted by the laws of each State through which the railway runs. In the East the ordinary fare for a single journey is usually between 1d. and 1½d. a mile, often the former. For a return ticket reductions are sometimes made and sometimes not. The more a single ticket costs per mile the more likely is there to be a reduction on the return ticket. Suburban tickets are issued at a lower rate than others, and season tickets of various sorts are also issued. The New York Central Railway, for instance, issues "50-trip family commutation tickets" between New York and stations on its various lines, and some cases more than 100 miles away, at prices ranging from 30 to 40 times the single journey fare. Such a ticket is valid for a year, and may be used by the person who has bought it, or by any member of his family, or servant, or visitor of his. "Sixty-trip monthly commutation tickets," valid for one month,

and to be used by one person only, are issued at prices varying from 35 times the single fare for very short distances, to less than eight times the single fare for a distance of more than sixty miles on a line where the trains are slow, and the holders will, presumably, not use them very often. "Forty-six trip monthly school tickets" are issued to school children or teachers at prices calculated on the same amount per journey as the "Sixty-trip monthly commutation tickets."

There is, as a rule, only one class of ordinary passenger carriage, but most express trains contain "parlor cars" for travelling, in which an extra fare is charged. This supplementary fare is received by the railway company if they own the "parlor cars," otherwise by the Pullman Company, or some other independent company who have a contract with the railway company as to the running of the vehicles. The same is the case with the ordinary sleeping carriages (which are almost entirely owned by outside companies) for a berth in which an extra fare must be paid varying in amount according to the accommodation required, but in no case less than the corresponding "parlor car" supplement. A berth in a "tourist car," which is a sort of second-class sleeping carriage, costs half as much as a berth in an ordinary sleeping carriage. The extra fares are supposed to be calculated on a time basis rather than a mileage basis—8s. 4d. a night, and 4s. 2d. a day for the ordinary accommodation—but in practice the sleeping carriage supplement usually approximates ½d. a mile throughout. The "parlor car" supplement is in some cases considerably less than this, and in others about the same. Dining cars are usually owned by the railways. East of Chicago the ordinary charge for all meals is 4s. 2d. each; west of Chicago meals are generally served *à la carte*, partly because travellers in this part of the country have less money to spare, and partly because it is found possible by this method to feed more people in a given time. It is generally found there is no profit in the dining-car business. The regular free allowance of luggage is 150 lbs., each 100 lbs. of extra luggage being charged at the rate of 12 per cent. of the single passenger fare. Travellers with round-the-world tickets, or when about to start on long ocean voyages, get 350 lbs. free.

In the United States the standard gauge is, as in Great Britain, 4 feet 8½ inches. Flat-footed rails laid upon transverse sleepers, without the intermediary of chairs, are practicallay always used. The rails are laid with broken joints (*i.e.*, the rail joints on either side are placed exactly or approximately opposite the middle points of the rails on the other side). The distance from centre to centre of two lines of rails is 13 feet. The clear headway above the level of the tops of the rails is about 15 feet. The loading gauge of American railways permits of the use of rolling stock of large size. The extreme width is often more than 10 feet, and the extreme height of the chimneys of some engines is over 15 feet. Big modern engines with their tenders frequently weigh in working order as much as 150 tons. This weight spread over a total wheel-base of about 60 feet is by no means small, but when the weights put upon the driving and coupled wheels are considered, the figures are made more striking. Taking Mr. Collier's figures, eight-coupled goods engines have as much as 90 tons upon the coupled wheels, extending over a wheel-base of no more than 17 feet, and some four-coupled express engines have 27 tons upon the driving wheels and 25 tons upon the coupled wheels. The power of the boiler is commensurate with the weight of the engine, the grate area being often more than 50 square feet, and the total heating surface being 3,000 and 4,000 square feet.

Mr. Collier says that the passenger trains are frequently heavy—between 300 and 450 tons—but, with certain exceptions, not particularly fast. The best speeds are found between Philadelphia and the seaside resorts of Atlantic City and Cape May, where in summer there are a certain number of really fast trains. From Atlantic City to Camden (a suburb of Philadelphia) *via* the Philadelphia and Reading line, one train in the summer of 1904 was for a time given only 49 minutes, start to stop, for the 55½ miles, while between Camden and Cape May, on the Pennsylvania Railway, there is a train which covers the 72·2 miles from Camden to Anglesea Junction in 73 minutes, start to stop. Between New York and Washington, through a thickly-populated district, and past the great cities of Philadelphia and Baltimore, a very good service is called for. There are two lines engaged in this traffic; the distance in both cases is approximately 227 miles, and it includes a ferry crossing into or from New York involving a loss of about a quarter of an hour. From New York to Washington there are 15 trains each day by the Pennsylvania, and 10 by the Baltimore and Ohio. The fastest takes 5 hours. There are three trains at this speed, and seven more in 5½ hours or less. A certain number of these trains perform start-to-stop runs at average speeds of over 50 miles an hour. On the New York Central route between New York and Chicago the "20th Century Limited" covers the whole 980 miles in 20 hours in either direction. There are a considerable number of trains making start-to-stop runs at over 50 miles an hour, and the "Empire State Express" even performs two runs at over 57 miles an hour. An examination of the time tables of other lines shows a certain rather restricted number of runs at 50 miles an hour or more. A considerable number of runs of 100 miles or more without a stop are performed. Further west the trains get slower and less frequent. The Illinois Central have three trains a day from Chicago to New Orleans, the fastest running at an average speed (including stops) of 35 miles an hour, and the Northern Pacific have two trains a day from St. Paul to Portland at rather less than 30 miles an hour.

Mr. Collier's report touches upon a variety of

topics—upon finance, Inter-State and State commerce commssions, signalling arrangements, electric traction, the making up of goods trains, railway accidents, safety legislation, brakes, automatic couplers, and much else of interest and importance to all concerned with railway affairs.

ADMIRALTY CHARTS.

The following is the official list of charts issued by the Hydrographic Department, Admiralty, in January and February, 1905:—

New Charts.—2076—Scotland, north coast:—Loch Eriboll. 3466—Germany. Jade river:—Wilhelmshaven. 180—Sicily: —Taormina road. 3473—West Indies. Cuba, south coast:—Santa Cruz del Sur and approaches. 146—Africa, west coast:—Niger river (Nun entrance). 3478—Africa, west coast. Niger river mouth:—Brass river. 3476—Bay of Bengal:—Naaf river. 3475—Philippine islands. Luzon, south-east coast:—Matnog bay and Tiklin strait. Port Gubat. 1764—China, east coast:—Amoy, inner harbour. 994—Japan. Nipon, south coast:—Yeboshi bana to Anori zaki, including Gokasho ko and Hamashima ko. Hasama ura. 3472—Japan, inland sea:—Ujino ko. 2401—Sea of Marmara. Plan added:—Beikos Umur and Buyukdéré bays. 2074—Mediterranean sea. Cyprus. New plan:—Kyrenia. 435—West Indies. Cuba. New plan:—Port Escondido. 2772—Eastern Archipelago. Anchorages in Gillolo. Plan added:—Loloda bay. 1394—China sea. New plan:—Entrance to Kuantan river. 2467—New Guinea. Plans and anchorages on the north coast. New plans:—Jamna road. Anus anchorage. 1510—Pacific ocean. Sandwich islands. Plan added:—Hanapepe bay.

Charts that have received additions or corrections too large to be conveniently inserted by hand, and in most cases other than those referred to in the Admiralty Notices to Mariners:—Index charts. A to V (omitting R). 1686—England, west coast:—Padstow bay. 2704—Ireland, west coast:—Blacksod bay. 1773—Ireland:—Queenstown and port of Cork. 2251—Baltic sea. Sheet II.:—Kalmar sound, &c. 2728—Spain, north coast:—Bidassoa river to cape Peñas. 1053—Spain, North-west coast:—Cape Peñas to Pontevedra bay. 689—Spain:—Gibraltar harbour. 366—Cape Verde islands. 565—Iceland, western portion. 321—North America. Lake Superior. 1148—West Indies. Leeward islands:—Ponce harbour. 2463—Alaska:—Port McArthur to Windham bay. 2462—Alaska:—Windham bay to Icy cape. 2461—Madagascar:—Nosi Vao to Purdy sand. 2871—Madagascar:—Nosi Bé, southern anchorages. 492—India, west coast:—Aguada to St. George island. 821—Bay of Bengal:—Elephant point to Chedúba strait. 823—Bay of Bengal:—Koronge island to White point. 824—Bay of Bengal:—White point to Mergui. 923—Eastern archipelago:—Botavia roads. 2578—Philippine:—Eastern part of the Sulu sea. 1262—China, south coast:—Hongkong to gulf of Liau-tung. 1199—China, east coast:—Kue shan islands to the Yang tse Kiang. 1602—China, east coast:—Approaches to the Yang tse Kiang. 1236—China, north coast:—Approaches to Port Arthur, &c. 2412—Japan:—Amoy to Nagasaki. 358—Japan:—The western coasts of Kiusiu and Nipon. 3254—Australia, north coast:—Norman river entrance. 2747—Australia, south coast:—Entrance to Port Phillip, &c. 1069—Australia, east coast:—Port Jackson. 1022—Pacific ocean, islands and anchorages in.

These charts are issued by Mr. J. D. Potter, 145, Minories.

THE VARIABILITY OF MODERN AND ANCIENT PEOPLES.*

In has been generally supposed that modern peoples deviate more widely than ancient peoples from their respective means. The writer's investigations upon the Egyptian fellahin, however, lend no support to this supposition, alike in length, breadth, and horizontal circumference of head and in cephalic index. The variability of the modern population of Kena and the neighbouring district is not sensibly different of that of inhabitants of the same region six or seven thousand years ago, as deduced by Miss Fawcett and others from the Nakada collection. So, too, the variability in cephalic index of ancient Bavarian skulls is found to be almost identical with that of the modern Bavarian population; and the variability of the cephalic index in modern French and English does not exceed, but is probably less than, that in ancient Gaulish and British skulls respectively.

More evidence is urgently needed, but what little we have supports the contrary hypothesis that modern and ancient populations living under like conditions of country and climate differ little in variability. Professor Karl Pearson, on the other hand, supposing that a diminishing struggle for existence encourages the persistence of individuals showing greater variability, believes that variability increases with increasing civilisation. The opposite view, however, appears tenable, that stringent selection encourages greater variability. It explains why in several features the oppressed Copts show greater variability than the Mohammedan population of Egypt, and the Whitechapel series of skulls of the 16th century is more variable than the general upper middle and upper class population of modern England. The more prosperous community tends to homogeneity; in other words, to regression towards its mean.

* Abstract of paper read before Section H of the British Association meeting at Cambridge, by C. S. Myers, M.D.

PHOTOGRAPHIC CHEMISTRY.

In his last Presidential address to the Royal Photographic Society, Sir William Abney, speaking of the progress which had been made in three-colour photography, said:—The advent into the market of two such extraordinary sensitisers as pinachrome and homocol will probably make the year a memorable one. The latter is the newest offspring of the chemist, and has yet to be investigated in a quantitative manner, but the qualitative examination of it shows that it has capabilities which no single dye has yet shown. He (Sir William Abney) had already published in the photographic press the conditions necessary to obtain an ideal photographic plate for the three-colour process, and shown that it is not the same as those necessary for perfect monochromatic work where colour luminosity is represented by various luminosity in black and white. The ideal three-colour plate then will be a separate entity from that of the ideal orthochromatic plate. It appeared to him that in the near future we may have the means of attaining closely these ideals even if we have not got them already. There is one thing, however, that he should have wished, and that is, that these new sensitisers might have come from British factories rather than from German. Had we fostered technical education amongst the middle classes in the past, as we are now endeavouring to do, we might have looked at home for the production of such sensitive derivatives. As the aniline dyes were first born in England, it is bitter to think that for want of trained men nearly the whole of these industries have left for foreign shores. But we have to thank our foreign chemists for having given to the world these products of their research. It is better to have them now than to have to wait unlimited time, till our home industry and research have revived.

TURKISH PREPARATIONS FROM GRAPE JUICE.

In Turkey considerable attention is devoted to the preparation of various articles from grape juice which are used as comestibles and are put up in a very convenient form for use when travelling. These are as follows:—"Basduk," in the manufacture of which freshly expressed grape juice is evaporated down to the consistency of molasses—a considerable amount of flour or starch is mingled with it and the mixture is spread in thin sheets upon cotton cloth and exposed for two days in the sunshine. After drying, these are then removed from the cotton (a damp cloth being applied to the reverse side in order to loosen the sheets), and for three months they are preserved in tightly closed jars. After this period there seems to be no risk of decomposition in the product, which resembles leather in pliability and appearance, the colour being that of the grapes employed at the outset. "Kesme" is another preparation which differs from the preceding in that coarse wheat grits are employed instead of flour and starch, and the resultant product is obtained in cakes half-an-inch thick, after drying on metal plates. It is less tough than the "basduk" and more savoury. In the preparation of "sujuk" (*rojik* in Armenian), walnuts are strung closely together on pieces of stout twine a yard long. These strings are immersed in the mixture of grape molasses and flour described above, and after receiving a coating about one-fourth of an inch in thickness are withdrawn and hung up to dry. The last two are preserved for a few months in jars, as in the case of the "basduk." These three preparations are said to be excellent articles of food, the last two being especially savoury. They offer much nutriment in a compact form, and are exceptionally well adapted for the needs of the Oriental traveller.

OBITUARY.

General Cooke, C.B.—Lieut.-General Anthony Charles Cooke, a life Member of the Society of Arts since 1883, died on the 6th April, at his residence in London. He was born in 1826, the son of the Rev. R. B. Cooke, Canon of York, and was educated at Southwell and the Royal Military Academy, Woolwich. He joined the Corps of Royal Engineers in 1844, and was director of the right attack at the Siege of Sebastopol in 1854. He was executive officer of the Topographical Branch of the War Office 1859-69, and commanded the Royal Engineers in Bermuda 1870-73, and at Alexandria 1873-78. He served as Director-General of Ordnance Survey of Great Britain and Ireland 1878-83. He was Colonel-Commandant Royal Engineers since 1900, and edited the Aide Mémoire for the Corps of Royal Engineers.

THE LIBRARY.

The following books have been presented to the Library since the last announcement:—

Arnold, Herbert.—The Popular Guide to House Painting, Decoration, &c. Manchester: John Heywood. 1905. Presented by the Publishers.

Australia, Year-Book of, 1904. Presented by the Agent-General for New South Wales.

Barlow, Glyn, M.A.—Industrial India. Madras: Natesan and Co. Presented by the Publishers.

Beadle, Clayton.—Chapters on Papermaking. Vol. I. London: H. H. Grattan. 1904. Presented by the Author.

Blondlot, R.—"N" Rays. A Collection of Papers Communicated to the Academy of Sciences, Paris. Translated by J. Garcin. London: Longmans, Green, and Co. 1905. Presented by the Publishers.

British Rainfall, 1903. Compiled by H. R. Mill, D.Sc., LL.D. London: E. Stanford. 1904. Presented by the Editor.

Brown, Adrian J., M.Sc.—Laboratory Studies for Brewing Students. London: Longmans, Green, and Co. 1904. Presented by the Publishers.

Bushell, Stephen W., C.M.G., M.D.—Chinese Art. Vol. I. London. 1904. Presented by the Board of Education.

Calcutta, Imperial Library.—Catalogue of Printed Books in European Languages. Part I. Two Vols. Calcutta. 1904.

Clausen, George, A.R.A.—Six Lectures on Painting. London: Elliot Stock. 1904.

Coghlan, T. A.—A Statistical Account of Australia and New Zealand, 1902–3. New South Wales Statistical Register for 1902 and previous years. Sydney. 1904. Presented by the Agent-General for New South Wales.

Cunynghame, H., C.B., M.A.—A Geometrical Political Economy. Oxford: Clarendon Press. 1904. Presented by the Delegates of the Press.

Douglas, James, LL.D.—Untechnical Addresses on Technical Subjects. New York: J. Wiley and Sons. 1904. Presented by the Author.

Dudley, Lucy Bronson.—A Royal Journey. New York. 1901. Presented by the Author.

Fry, George, F.L.S., F.C.S.—The Varnishes of the Italian Violin Makers of the sixteenth, seventeenth, and eighteenth Centuries, and their influence on Tone. London: Stevens and Sons, Ltd. 1904. Presented by the Author.

Griffiths, Harold.—The Plenum or Propulsion System of Heating and Ventilation. London: Simpkin, Marshall and Co., Ltd. 1905. Presented by the Author.

Hawkins, Cecil, M.A.—Elementary Geometry. Part I. London: Blackie and Son, Ltd. 1904. Presented by the Publishers.

India, Progress of Education in. Fourth Quinquennial Review. 1897–8 to 1901–2. London. 1904. Presented by W. Pollard Digby, Esq.

India, Rainfall Data of, 1903. Published by the Meteorological Department of the Government of India. Calcutta. 1904. Presented by the Department.

Johnson, W. H.—The Cultivation and Preparation of Para Rubber. London: Crosby Lockwood and Son. 1904. Presented by the Publishers.

Jordan, W. Leighton.—Astronomical and Historical Chronology. London: Longmans, Green and Co. 1904. Presented by the Publishers.

Kerr, John G., LL.D.—Constructive Geometry. London: Blackie and Son, Ltd. 1904. Presented by the Publishers.

Laking, Guy Francis, M.V.O., F.S.A.—The Armoury of Windsor Castle. European Section. London: Bradbury, Agnew and Co. 1904.

Lehfeldt, R. A., D.Sc.—Electro-Chemistry. Part I. General Theory. London: Longmans, Green and Co. 1904. Presented by the Publishers.

London County Council.—London Statistics, 1903–4. Statistical Abstract for London, 1904. Annual Report of the Proceedings of the Council for the year ended 31st March, 1904. Presented by the London County Council.

Mendeléeff, D.—The Principles of Chemistry. Translated from the Russian by G. Kamensky, and edited by T. H. Pope, B.Sc. Two vols. Third English Edition. London: Longmans, Green and Co. 1905. Presented by the Publishers.

New Zealand Official Year-book, 1904. Wellington, New Zealand. 1904. Presented by the Registrar-General.

Parkinson, John.—Lays of Love and War. Ardrossan: A. Guthrie and Sons. Presented by the Author.

Phipson, Cecil Balfour.—The Redemption of Labour; or Free Labour upon Freed Land. Two vols. London: Swan Sonnenschein and Co. 1888 and 1892. Presented by the Author.

————The Science of Civilisation. London: Wm. Hutchinson and Co. 1903. Presented by the Author.

Ricci, Luigi.—Italian Grammar for English Students. London: The Walter Scott Publishing Co., Ltd. 1904.

Roberts, Rawdon, B.Sc.—Preliminary Geometry. London: Blackie and Son, Ltd. 1904. Presented by the Publishers.

Schlich, W., Ph.D., C.I.E., F.R.S.—Forestry in the United Kingdom. London: Bradbury, Agnew and Co., Ltd. Presented by the Publishers.

————Manual of Forestry. Vol. 2. Sylviculture. 3rd Edition. London: Bradbury, Agnew and Co., Ltd. 1904. Presented by the Author.

Sennett, A. R.—Across the Great St. Bernard. London: Bemrose and Sons, Ltd. 1904. Presented by the Author.

Strange, Edward F.—Japanese Colour Prints. London. 1904. Presented by the Board of Education.

Thompson, A. Beeby.—The Oil Fields of Russia and the Russian Petroleum Industry. London: Crosby Lockwood and Son. 1904.

Turnbull, V. M.—Elementary Plane Geometry. London: Blackie and Son, Ltd. 1904. Presented by the Publishers.

Victorian Year Book, 1903. Melbourne. 1904. Presented by the Government Statist.

Wardle, Sir Thomas.—Kashmir: Its New Silk Industry. London: Simpkin, Marshall and Co. 1904. Presented by the Author.

Webber, General, C.B., R.E.—General Sir Henry Drury Harness, K.C.B., Colonel Commandant Royal Engineers. London. 1903. Presented by the Committee of the Royal Engineers Institute, Chatham.

Winch, William H., M.A.—Notes on German Schools. London: Longmans, Green and Co. 1904. Presented by the Publishers.

GENERAL NOTES.

ALCOHOL COMMITTEE.—The *Standard* of the 12th inst. gives the following anticipations of the Report of Committee on the Industrial Uses of Alcohol. The evidence taken by the Alcohol Committee, whose report is now in the hands of the Chancellor of the Exchequer, will be found to have been strongly in favour of the remission of the duty on spirits employed in various textile manufactures. It was directed towards the recall on preferential terms of a large number of trades which have been abandoned in this country owing to cheaper methods or more liberal encouragement abroad. It will be found, we believe, that the recommendations of the Committee favour the balance of the evidence, and suggest the removal of many restrictions which have been brought to light by the inquiry. In Germany, alcohol used in local manufactures is duty free. In England, the duty is legally recoverable by the manufacturer on "making out a case" for the Inland Revenue. It is a curious feature of the recent investigations that this latter fact seems to have been unknown to the manufacturers themselves. Thus the various industries using alcoholic spirit may, quite apart from the Committee's report, should it touch the point, seek exemption from the duty if they simply use their powers under the Act.

SUGAR AND THE CONVENTION.—In his report for 1904 on the trade of the Netherlands, just issued (No. 3331, Annual Series), Mr. Consul Robinson refers to sugar, and makes some observations that may be read with interest. The past year was one of considerable importance to the sugar trade of all European countries, being the first year of the application of the Brussels Sugar Convention. The ultimate consequences, says Mr. Robinson, "cannot as yet be entirely appreciated for the reason that it came into operation simultaneously with a large deficiency in the beet root crop. An active and extensive speculative demand sprang up in consequence, and the prices of both beet and cane sugars have been considerably advanced." Beet sugar, quoted at about 8s. 4¾d. per cwt. at the beginning of the year, closed at about 14s. 5½d. on December 30. Cane sugar from Java rose from 9s. 3d. per cwt. to 15s. 3d. per cwt. in the same period. "The part played by the Brussels Convention in this connection," says the consul, "appears to many competent observers to have been unduly exaggerated; they express the opinion that the probable effect of the deficient crop has been immediately exaggerated by an army of speculators working on the apprehensions of the public, and that the coming into force of the Convention would, apart from simultaneous deficiency in supplies, have had but a comparatively insignificant effect on prices."

DEVELOPMENT OF AGRICULTURE IN THE MALAY PENINSULA.—It was decided at the last general meeting of the Malay Peninsula Agricultural Association, to offer two prizes for essays on "Rubber, its cultivation, mode of tapping and manipulation," one prize to be for Para Rubber, and the other for Gutta Rambeng. The Government last year inaugurated a series of agricultural shows, the next of which is to be held at Penang, in August next. In view of the scarcity of Indian coolie labour, the question of getting labourers from Java was mooted.

COOLIE LABOUR IN FIJI.—According to the Annual Report on Indian Immigration for 1903, the experiment has recently been tried of sending coolies to Fiji from Madras instead of from Calcutta. The general results have not been satisfactory by reason of the fact that during the first eight months the percentage of sickness among Madras immigrants was much higher than is usual among new arrivals, while their wage-earning power was about one-fourth less than the average of other immigrants on the same estate.

INDIAN STEEL.—According to advices from Calcutta, the production of rolled steel in India on a commercial scale from indigenous material has recently been effected by the Bengal Iron and Steel Company, at their Barraker works. At present some 500 tons of structural steel are produced, but large rail rolling mills are contemplated for the purpose of supplying the Government and other railways. At present 1,000 tons of pig-iron are produced each week, part of which is used by the Bengal Iron and Steel Company itself for railway sleeps, cast-iron pipes, columns, &c.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, APRIL 17...Optical, 20, Hanover-square, W., 8 p.m. Mr. A. J. Bull, "Some Notes on the Nature of Vision."

British Architects, 9, Conduit-street, W., 8 p.m. Mr. Mervyn Macartney, "Garden Architecture."

Actuaries, Staples Inn Hall, Holborn, E.C., 5 p.m.

Victoria Institute, 8, Adelphi-terrace, W.C., 4½ p.m. Dr. J. M. Peebles, "Essays on Immortality."

TUESDAY, APRIL 18...Civil Engineers, 25, Great George-street, S.W., 8 p.m. Annual General Meeting.

Pathological, 20, Hanover-square, W., 8½ p.m.

Zoological, 3, Hanover-square, W., 8½ p.m.

WEDNESDAY, APRIL 19...Meteorological, 25, Great George-street, S.W., 7½ p.m. 1. Mr. W. H. Dines, "An Account of the Observations at Crinan in 190 , and Description of a new Meteorograph for use with Kites." 2. Dr. Hugh Robert Mill, "Rate of fall of Rain at Seathwaite."

Geological, Burlington-house, W., 8 p.m.

Chemical, Burlington-house, W., 5½ p.m. Mr. W. C. Ball, "Complex nitrites of bismuth."

Microscopical, 20, Hanover-square, W., 8 p.m. 1. Mr. A. E. Conrady, "The Application of the Undulatory Theory to Optical Problems." 2. Exhibition of Pond Life

Sanitary Engineers, 19, Bloomsbury-square, W.C., 7 p.m. Mr. E. R. Palmer, "The Ventilating, Flushing, and Cleansing of Sewers and Drains."

Journal of the Society of Arts.

No. 2,735. VOL. LIII.

FRIDAY, APRIL 21, 1905.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

NOTICES.

CONVERSAZIONE.

The Society's Conversazione this year will take place at the Royal Botanic Gardens, Regent's-park, on Tuesday evening, July 4, from 9 to 12 p.m.

The programme of arrangements will be announced in future numbers of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

COLONIAL SECTION.

Tuesday Afternoon, March 28th; The HON. SIR JOHN ALEXANDER COCKBURN, K.C.M.G., in the chair.

The CHAIRMAN said he was very proud of the honour, as a member of the Colonial Committee, of introducing Mr. James, the Agent-General for Western Australia. Mr. James had a distinguished record in Australia, both as Premier of Western Australia and as a member of the Federal Convention. He was also one of the fathers of the Commonwealth, being present at the conference which framed and finally adopted the Commonwealth Constitution.

The paper read was—

THE MANUFACTURES OF GREATER BRITAIN. II.—AUSTRALASIA.

By THE HON. WALTER JAMES, K.C.,
Agent-General for Western Australia.

No question giving rise to comparisons between the work of one country and that of others can be satisfactorily disposed of unless, by the use of a few "fore words," those special features are referred to which indicate local conditions, and thus make fair comparisons possible. In few questions is this so much the case as in those affecting manufactures which depend for their growth not alone upon the total population of the country, but upon natural limitations or advantages which retard or stimulate production or distribution. There are certain features in Australasia which closely affect both production and distribution, and the mere enumeration of results can afford no real evidence as to the manufacturing energy of the people unless these conditions are known and appreciated.

GEOGRAPHICAL DIFFICULTY.

Australia has a population of 3,906,000, and New Zealand a population (exclusive of Maoris) of 800,000. If that aggregate population were comprised within the 105,000 square miles which represent the area of the latter colony, instead of being scattered over an area of 3,000,000 square miles, it cannot be disputed that the manufacturing results from the same number of people would be quite different from what they are or can be at present. There would then exist a relative concentration, both of manufacturing efforts and accessible markets, and so comparatively close a geographical connection between producer and consumer, that external supplies would have to confront greater and better organised competition whilst enjoying far less favourable conditions than those which exist to-day in the scattered population and wide-spread seaboard of Australasia. The present industrial position of the State of Victoria is perhaps the most advanced in manufacturing activity in Australia; and amongst other causes the main one has been its concentration of population in a comparatively small area and in readily accessible centres. These conditions have enabled the local manufacturer to capture the home market so fully that he has secured a firm footing upon which to build an extra-State trade which is rapidly growing.

Australia's area comprises very nearly

3,000,000 square miles; the 30 degrees of latitude through which she runs her length of 1,971 miles and the 40 degrees of longitude that cover her lateral expanse of 2,400 miles give every variety of climate, from temperate to tropical. Almost along the entire seaboard of this huge area is scattered her small population of less than 4,000,000 people; and though the main centres of population may be found in a limited number of localities, they are so widely separated that the manufacturer's market is almost as extensive as the geogaphical limits of the island, and to supply these centres entails an amount of seaborne transport that the home producer in no other country has to face.

New Zealand contains a population of 800,000, and her area comprises 105,000 square miles; and in her case also, though settlement may be relatively more concentrated than that of Australia, it is still so extended that the manufacturer finds himself under difficulties of the same kind though less in degree, in his competition with the oversea producer.

The scattered nature of the population of Australasia is inevitable when one bears in mind that the three main industries—Agricultural, Pastoral, and Mineral—are carried on at almost every part of the vast area, and carried on so vigorously that in 1903 Australasia exported domestic produce alone to the enormous amount of £60,417,000.

If one examines the map of Australia it will be found that in each State the main consuming and distributing centres are nearly all ports on the seaboard open to oversea vessels. In Queensland, Townsville, Rockhampton, Maryborough, and the capital, Brisbane, are the chief consuming and distributing centres and together contain a population of 170,000, and it is through these centres that the trade of the State is practically done. In New South Wales, Sydney and Newcastle together contain a population of nearly 600,000, and are both main ports through which the State receives its imports and from which the interior is supplied. In Victoria, Melbourne contains a population of nearly 500,000, and practically stands upon the shores of an over-sea port, through which nearly all imports into the State pass. In South Australia, Adelaide and Port Adelaide contain a population of 180,000 and serve as the great and almost only door to the import trade of the State; and again in Western Australia, Perth and the metropolitan area contain a population of 80,000, and all the import trade of the State passes through its doors, which are open to all oversea shipping. The same conditions apply at Hobart and Launceston in Tasmania, with a population of 56,000. In New Zealand the same conditions obtain, the main centres of population and distribution being Wellington with 50,000, Christchurch with 60,000, Dunedin with 53,000, and Auckland with 70,000; a total of 220,000 living at ports open to oversea shipping, and through which the great bulk of the colony's trade passes. Nearly all the chief centres of population which form the main markets of the manufacturer stand on or are directly served by oversea ports. In all these cases oversea manufactures are unloaded from the ships which bring them direct from the external manufacturers' works and land them direct into the main consuming and distributing centres of the local market. When one appreciates how comparatively light is the cost of sea-borne transit on long voyages in large steamers not bound to time, it will be seen that, so far as natural protection is concerned, the Australasian manufacturer's main market is, under present conditions of small and scattered population, just as open to oversea productions as to his own. At present, moreover, Australasian manufacturers are principally established at ports, and as a consequence both local and oversea producers meet at the common starting-points from which distribution has to be effected. The same railway journey and the same charges for internal distribution meet both competitors when once the goods are landed. The Australasian manufacturer, with his main markets situate at or immediately served by widely-separated oversea ports, and his main manufacturing works similarly situated at ports, finds that at all these ports oversea shipping calls regularly and constantly, and the stream of oversea importation thus flows past the very doors of his factory.

Inter-State Distances.

The Australian manufacturer who desires to capture the Commonwealth market has to allow for long sea journeys. Townsville is five days' sea trip north of Sydney; Melbourne, Adelaide, Perth, Hobart and Launceston are from two to nine days' sea journey south-west from Sydney; Wellington, Christchurch, Auckland and Dunedin are likewise separated from each other by a sea voyage of 20 to 36 hours' duration, and it is upon these sea distances that the manufacturer has to calcu-

late. It will be readily realised that such great distances separating the Australian manufacturers from the Australian consumers create a serious handicap in supplying so comparatively limited and so very scattered a market, whilst on the other hand such features offer great advantages to the oversea producer who, from one steamer on the one voyage, drops his goods at Perth, Adelaide, Melbourne, Sydney and Brisbane, and often does the same in New Zealand. As between Australia and New Zealand there is a distance of five to six days, and local manufacturers in each country competing for the trade of the other have to face that handicap of distance as well as the barrier of protective duties. These geographical difficulties, which stand in the way of the effort of the Australasian manufacturer to capture his own market, do not exist in Canada. The external trade has but few inlets open to deep sea vessels, and these inlets are not separated by distances so great as that between Brisbane and Perth. The internal trade is distributed from centres very widely scattered and situated many miles from oversea ports, requiring days of railway or canal journeying, whilst it is served by factories which are themselves placed far inland. The oversea producer has not only to face the cost of his sea journey but the far more serious charge of a long inland trip before he reaches his market and his competitor. He then commences to compete at a handicap measured by sea freight plus handling and internal transit charges; with us the latter charges are common to local and oversea manufacturers.

The difficulties which I have referred to, though considerable to-day, are not of permanent importance; as population grows and the volume of local manufactures increases the market of each State will encourage and justify more wholesale and less costly methods of supply and distribution. In the discussion and consideration of the present state of Australasian manufactures it should also be borne in mind that the

Age of the Australian Manufacturing Industry

is rather under four years. It was only made possible in October, 1901, when the old Inter-State tariffs were abolished and a Commonwealth Customs Act adopted. That was the first date on which an Australian trade could exist, and was the first inducement offered local manufacturers to build up factories and establish methods capable of supplying and suitable to the requirements of the Commonwealth. Prior to that date there were six States, the largest of which contained a population of 1,500,000, the smallest a population of 172,000, and so strong was local feeling that (with the exception of New South Wales) every State treated the importations from its neighbour on exactly the same footing as it taxed imports from other parts of the world. There was no preference, all were treated alike, and there grew up such a feeling of inter-State antagonism, that for many years all movements towards federation were thwarted by the fiscal difficulties involved, and federation only became an accomplished fact when the native-born Australians determined to secure union before these antagonisms became fundamental. The Australian manufacturers to-day, therefore, are but the children of yesterday, and even yet there has been no time to establish those larger works and to adopt those wider business methods which the expanded openings demand. Canada secured unity in 1867, and, from that time onward, the local manufacturer had a market as wide as the Dominion. In 1879 came his first real opportunity with the adoption of a national policy by Sir John McDonald, and for the past twenty-five years Canada has enjoyed a protective tariff which ensured to its manufacturers the control of Canadian markets. The real growth of its manufacturing industry is, however, of more recent date—some seven or ten years, and would appear to be due to the recent expansion of the far North-West and also to no inconsiderable extent to American capital and American management desirous of supplying the Canadian markets which are now opening. The first ten years of Australian manufactures will, I am confident, leave behind a much more striking record than that accomplished by Canada during the first twenty years of her protected Dominion market.

Mr. Just, in his paper dealing with the manufactures of Canada, states that *inclusive* of dairy factories the position in Canada in 1901 was as follows:—

Establishments	14,650
Capital invested	£93,000,000
Cost of material	£55,500,000
Value of products	£100,200,000
Number of employees	306,694

The position in Australasia *exclusive* of butter, cheese, and cream factories in 1902 was as follows:—

Establishments	15,364
Capital invested	£73,000,000
Cost of material	£53,000,000
Value of products	£92,000,000
Number of employees	248,735

These figures must not be taken as affording an exact comparison, as Canada appears to exclude factories employing less than five hands; in Australasia the State methods vary on this head, and apparently include factories containing less than five hands. On the other hand, Australasia excludes butter and cheese factories, and appears to show better results on the capital invested. I use the figures merely to indicate that the manufacturing energy of Australasia, despite its long wars of inter-state tariffs, bears no unfavourable comparison when brought side by side with Canadian results, after 37 years of federation and 25 years of a national and protected market, with much more effective natural protection and a much larger population than is enjoyed in Australasia.

New Zealand is industrially independent in the sense that she is fiscally at arms length from the Commonwealth. In that respect she stands to-day in the same relation to Australia that each State of the Commonwealth stood to the other before 1901. Her industrial development therefore will proceed on the lines of the past, benefited no doubt by the central and unified control of Australian Customs laws, but also not unaffected by the increased strength which Australian manufacturers will acquire from the possession of so much more extensive and valuable a protected market. Whether between the Commonwealth and New Zealand reciprocal trade relations will spring up it is difficult to foresee owing to the similarity of production, but it is impossible to believe that something will not be accomplished in this direction.

Australasia's Gross Production.

It will be gathered from these introductory remarks that the manufacturing development of Australasia rests with the immediate future under the freer conditions and wider markets now available; but the results already attained under the most adverse circumstances testify in a striking manner to the manufacturing activity of the country and the value of the Australasian market. The local manufacturer has a market far distant from centres of opposition, but yet so close to extensive oversea openings that few countries offer such inducements for the profitable application of manufacturing industry. Its geographical position should enable Australasia to control the great bulk of the Pacific trade. Its nearness to the East places it on more favourable terms than any other white people, whilst its distance of six weeks from its nearest competitor gives it in its home and external markets for manufactured goods an advantage which will remain a permanent factor in its favour. As long as external manufactures made by white people are being imported into the East there will continue to be openings for the Australasian factory, and in the competition for that trade there are many elements which tell in favour of Australasia immediately her factories have grappled with the home market. Until the States of Australia became united, no Australian growth of manufacturing industry was possible; no factory could exceed the demands of its limited market, and no foundation could be obtained on which to meet external competition. The few years which have passed since Federation, have already shown a marked expansion of local manufactures, imports have fallen from £37,800,000 in 1903, to £34,600,000 in 1904, although during the latter year exports increased by £9,600,000, and there are abundant evidences of the manufacturers' determination to meet the altered conditions brought about by Federation.

In December, 1903, the population of Australasia was upwards of four-and-three-quarter millions of people, an increase from four-and-a-half millions in 1901. Adopting these latter figures as being most complete for statistical purposes, the bread-winners numbered 1,979,484, and comprised 43·67 of the population; a percentage which disclosed an increase on past years, and is still growing. Of these 645,057 were primary producers, and 527,387 engaged in industrial occupations. Of this latter number 248,735 were employed in factories in different branches of the manufacturing industry,

The agricultural, mineral, and pastoral industries of Australasia are well known, and their great productiveness is apt to obscure the great manufacturing activity of the country; the more so as the manufactured article is consumed locally, and is not, therefore, so well known as Australian gold or wool, or New Zealand mutton or dairy produce. The total production of Australasia for 1902 was no less than £139,800,000, arising from the agricultural, pastoral, dairying, mining, forest and manufacturing industries. Of this sum the

industries named produced the following portions:—

	£
Agriculture	28,826,000
Pastoral	28,689,000
Dairying (including butter and cheese factories and creameries)........	14,274,000
Mining	24,954,000
Forest and fisheries	4,018,000
Manufactories (exclusive of butter, cheese, bacon, and cream)	39,048,000

For 1903 the total production has increased by seven millions.

This production of £39,000,000 was contributed to by the various States as follows:—

I.—Value of Production of Manufactories for 1902.

State.	Value of Production.	Value per Inhabitant.
	£	£ s. d.
New South Wales....	11,452,000	8 4 4
Victoria	10,734,000	8 17 10
Queensland	3,237,000	6 6 3
South Australia	2,883,000	7 17 10
Western Australia ..	2,423,000	11 16 5
Tasmania	1,389,000	7 18 2
Commonwealth	32,118,000	8 6 5
New Zealand	6,930,000	9 1 6
Australasia	39,048,000	8 7 8

Manufacturing Production.

It will be observed that, though the aggregate productions of the primary industries exceed the result from manufactories, the latter is by far the most important single industry, being eleven millions in excess of agriculture or pastoral, and fifteen millions larger than the returns from minerals. If the manufacturing figures were credited with the output of butter and cheese the result would be still more pronounced in favour of the manufactories output. This aggregate production is equal to £30 per head of the total population; being £21 12s. from primary industries and £8 7s. 8d. per head from manufactories. Of primary production Australasia alone produces from these heads in an ordinary year more per inhabitant than is produced from the combined industries of any other country; the Australasian production of £21 12s., being most nearly approached by Canada—£16 5s. 6d., United States £14 14s., and France £11 11s. 6d. It is not to be expected that comparative results so unique as these should be shown by an analysis of the manufacturing production of the country; great and energetic workers as Australasians have shown themselves to be, the productive power of so small a population is limited, and their pre-eminence in primary production on a capitation basis is, of course, the main factor in their gross productiveness. The manufacturing industry in its output of £39,048,000 has, however, a great record, and one which is profitable alike to the community, and to those directly engaged in it. As recording the value of the articles produced by the factories and indicating the profits derived from the industry, one finds that the total gross output of the factories (exclusive of butter, cheese and bacon factories, and creameries which are not dealt with under the head of manufactories, but credited to the pastoral industry) was £92,032,000, of which £52,984,000 represents the value of the materials and fuel used, and leaves £39,048,000 as the value added in the processes of treatment, and the output, therefore, properly credited to manufacturers. Of this sum of £39,000,000, £18,600,000 represent wages paid, and the balance of £20,400,000 remains as the manufacturers' profit, subject to rent, insurance, depreciation, &c. Whether that represents a fair profit or not I must leave to those who are more fully cognisant than I am of what manufacturers obtain or reasonably expect, but on that point some light may be thrown by some further statistics.

Comparative Cost of Manufactures.

The expansion of American trade of recent years has been so striking that numberless inquiries have been made with a view of ascertaining the reasons. Put shortly, the conclusion arrived at would appear to be: high wages and efficient workmanship, with new and labour-saving machinery and adequate exertion during working hours. The results achieved are too apparent to leave room for ignoring or discounting these factors, and as a consequence the American artisan and mechanic is extolled. Side by side with this admiration for the American is—to use a mild expression—a total want of appreciation of the Australasian workman. Yet the Australasian artisan is just as well educated, quite as intelligent, and just as hard, if not a harder, worker than his American cousin. I have met employers of various kinds of labour with experience of different workmen, and I have heard an almost general testimony to the Australasian worker. Side by side with

strongly-expressed criticisms of political questions—which are irrelevant in assessing the industrial value of a man's work—there has been no want of appreciation of his value as an industrious and intelligent worker. In this connection, Mr. Coghlan, the well-known statistician of Australia, has prepared a Table dealing with the cost of production in the manufacturing industries (excepting butter, cheese, &c., as already mentioned) in New South Wales, New Zealand, and the United States. He finds that the figures of New South Wales and New Zealand are substantially in accord, and in dealing with their joint figures takes the total gross output of these two countries from manufactories (£39,160,289), and shows that the expenditure incurred amounted to £33,342,071, made up as follows:—

	£
Value of materials	21,764,769
Fuel	725,428
Wages	8,379,507
Miscellaneous expenses	2,472,367
	33,342,071

leaving a balance of £5,818,218 which provides for interest on capital embarked and trade losses and profits. This latter figure represents 17·5 per cent. of all the items included in cost of production, or 14·9 per cent. of the value of the production itself. In other words, for every hundred pounds worth of goods produced in the factories of the two countries, the following were the proportions of the various elements included in the price of the goods as they left the manufactories:—

Materials and fuel	57·4
Wages	21·4
Miscellaneous expenses	6·3
Interest, provision for trade losses, profits, &c.	14·9
	100·0

The United States returns for 1900 give some figures dealing with the same subject, with this result:—

Value of materials used, including fuel	56·5
Wages	21·0
Miscellaneous expenses	7·9
Interest, provision for trade, losses, profits, &c.	14·6
	100·0

A study of these comparative figures should remove some widely entertained misconceptions as to the efficiency of Australasian labour, the percentage of labour cost in America and Australasia being almost the same. In such a comparison the results become more favourable to Australasia when the smallness of its factories and the consequent limitation of their turnover is compared with what exists in the States. Tables A and B annexed show the average wages paid so far as figures are available.

The general figures I have mentioned point to the great activity of the Australasian manufacturing industry, and show its cost of production and resulting profits; whilst the last comparison shows very clearly the efficiency of Australasian labour employed in that industry.

Trade of Australasia.

The total has grown much more rapidly than the population, and under normal conditions the commerce of Australasia per head is (excluding transit and re-export) only exceeded by one country in the world, namely, Belgium, and in our output of primary productions alone on a capitation basis we exceed the production from the combined industries of even that country. Including inter-state movements the Australasian imports during 1903 amounted to eighty and a quarter millions and the exports to nearly ninety-two and three-quarter millions, a total of £36 9s. 6d. per head. Of the total exports the inter-state trade represents £29,500,000, and the export trade passing to and from New Zealand amounts to £4,000,000, so that the export of Australasia to external countries amounts to fifty-nine and a-quarter millions. Of the total imports, £29,600,000 are inter-state and £4,500,000 represent the imports between New Zealand and the Commonwealth, leaving an import trade from countries outside Australasia amounting to forty-six and a-quarter millions. I do not object to the elimination from these figures of the inter-state and purely internal trade of the Commonwealth, but in estimating the trade of Australasia (*i.e.*, Australia and New Zealand) there is no reason whatever why the volume of it should be lessened by deducting the trade between the two fiscally and constitutionally independent States any more than there would be justification for treating the figures of the United Kingdom as if its imperial trade were local and internal. The correct way to place the figures therefore, is to eliminate local inter-state trade of the Commonwealth only with this exact result:—

Australasian exports for 1903 .... £63,130,542
,, imports ,, ... 50,600,146

giving a total external trade of £113,780,688. The import trade is almost entirely for local consumption; the re-exports being very limited. As regards export trade there is practically no export of goods manufactured from foreign materials. Of a total Australian export trade of £12 5s. 11d. per head, the exports which are not Australian produce, only amount to 13s. 3d. per head; the same results exists, I believe in New Zealand. The three primary industries of Australasia, pastoral (including meat and wool), mineral (including gold) and agricultural (including dairy produce) practically comprise the export trade of Australasia. Attention has been almost exclusively devoted to primary productions, and so huge an export from station, farm, forest, and mine fully accounts for the occupations and the remunerative employment of the people, and, at the same time, explains how infinitesimal a portion of our exports represent manufactured articles in the popular sense.

PRESENT MANUFACTURING POSITION.

There is a capital of £73,000,000 employed in the 15,000 establishments, in which the work is conducted throughout the country. The horse-power actually employed amounts to nearly 200,000, and the value of machinery and plant to upwards of £25,000,000. The number of hands employed in factories is about 250,000; the main centres of activity being in Victoria, New South Wales, and New Zealand, where population is more concentrated and numerous than in any other State. (The annexed Tables, C—G, afford more details under this head.) The average number of hands employed in factories is small, though several large establishments exist. But the smallness of the factory was enforced by the strict limitation of markets under the old fiscal systems of the separate States. The manufacturer of locomotives could not command a large market in 1,500,000 people; nor the hat maker in 1,250,000; nor the wine maker in 360,000 people; nor the pure woollen maker in 800,000. Already has begun the tendency to increase the size and output of factories, and the next few years should witness a great and beneficial change in larger factories with increased output at reduced cost.

The progress of the manufacturing industry in Australasia has always been irregular, and though the increase in hands employed since 1885 shows a growth proportionately much greater than that of the population, as a matter of fact the greater part of the extension has been due to the past seven or ten years, and this relative advance has therefore been still more marked. The following Table indicates this;—

II.—THE FOLLOWING TABLE SHOWS THE GROWTH OF THE FACTORIES SINCE 1885.

Year.	Establishments.		Hands employed.	
	Commonwealth.	New Zealand.	Commonwealth.	New Zealand.
	No.	No.	No.	No.
1885	8,632	1,946	105,265	22,095
1890	8,903	2,254	133,147	25,633
1895	8,247	2,459	133,631	27,389
1900	10,040	3,668	184,160	48,718
1903	11,979	3,960	196,424	52,628

The manufactures of Australasia are, however, as a whole domestic; they naturally arise from the circumstances of the population or are connected with the treatment of perishable products, but there are nevertheless a fair number of firmly established industries of a more complex character, *e.g.*, locomotive, tweed, piano, hat, billiard table, and paper factories.

Of the persons employed in factories, 13,000 are employed in the treatment of perishable products for immediate use, and 123,000 in industries dependent upon natural resources, there are 113,000 engaged in industries which to a greater or less extent come into competition with imported goods. The distribution of these factories is given in Table III. on p. 604.

Of those employed in competitive factories there are certain lines in which the local manufacturer must be always a producer, however great may be foreign competition, or however "free" may be the imports.

As the great bulk of Australasia's manufactures are domestic and not of articles manufactured for an export trade, a very short reference to them will be necessary; the main interest centreing at present in the wealth and productive activity shown by Australasia as a whole. Australasia imports all her iron for reasons I shall presently indicate; her exports of timber are of the undressed kinds; she does not at present grow cotton. Her exports, in which these lines form a part, would therefore be practically all re-exports, but the proportion which represents these items made into manu-

factured articles for export is so extremely limited that they are a negligible quantity. Practically speaking, there are no exports of machinery, cotton goods, or woodwork, and Australasia does not at present compete with the outside world in external markets except in connection with the products of her three primary industries. Australasian manufacturers desire to meet the local demands as far as practicable; they have yet much to do before that end is accompiished. When, however, that position is achieved in any main line, the question of an export of manufactured articles competing with the producers of other countries will become a practical one. In the meantime, it may for all practical questions be disregarded in the consideration of Australasian manufactures. In the references, therefore, I now make to certain main lines of import, I shall do so more for the purpose of indicating the large field of consumption which is open to the local manufacturer than any desire to be exclusive.

TABLE III.

State.	Employed in domestic industries for the treatment of perishable products for immediate use.		Employed in industries dependent upon the natural resources of the country.		Employed in industries, the production from which comes into competition with imported goods.	
	Males.	Females.	Males.	Females.	Males.	Females.
New South Wales	3,573	51	26,513	5,696	22,367	7,433
Victoria	3,490	43	20,772	13,730	25,172	10,022
Queensland	1,337	43	8,394	2,263	6,408	841
South Australia	794	11	6,717	3,106	7,192	824
West Australia	883	3	6,567	1,097	3,044	289
Tasmania	378	21	3,935	723	2,129	563
Commonwealth	10,455	172	72,898	26,615	66,312	19,972
New Zealand	2,441	52	21,173	2,029	17,408	9,525
Australasia	12,896	224	94,071	28,644	83,720	29,497

The following are a

Few Leading Lines.

Food and Drink (including stimulants and narcotics, and agricultural products and groceries).—The local factories deal with bacon, butter, cheese, and other dairy lines, meat and fish preserving, jams and fruits, biscuits, cornflour, cigars, tobacco, beer, and other such articles, employing altogether about 39,000 hands. There is a large export of frozen meat, of wheat and flour, and a large and growing production of sugar and molasses. The wine industry should provide one of Australia's greatest outputs, and there can be little doubt that the importation of still wines must fall off as the conditions of vine culture are better understood. The wine-making grapes grow to great perfection in a large part of Victoria, South Australia, New South Wales, and in Western Australia, though at present the chief output of wine comes from Victoria and South Australia. Unfortunately, the fact that any kind of grape could be grown has caused vignerons to spread themselves over all varieties. The experience arising from internal competition has now created a tendency to specialise, and as a result, where there is a specialisation and concentration of effort, the home trade is being captured, and there is good promise of large exports. The importation is even now being more limited each year to the very high-priced wines which enjoy a special demand. The possibilities of an extended export trade in this line are apparent, and the next few years will witness it.

The imports in the way of stimulants from Great Britain are mostly whisky lines and beer in bottles, or beer in bulk sent to Australia to be bottled before going on the market. In such a line as stout, "Guinness," bottled by various firms, has a monopoly of the market. The bulk brewing trade is wholly a home trade. Where Australian breweries are opening up a bottled trade, it is in the lighter brew which comes more into competition with German "Lager Bier" than with the British bottled trade, the latter being too heavy as well as too expensive for local tastes.

It may help to remove another misconception in relation to Australasia if I point out that its consumption of intoxicants compares

most favourable with European and other manufacturing countries. The consumption per head in gallons of proof spirit being :—

United Kingdom..........	3·57
France	5·10
Germany	3·08
Italy	3·40
Holland..................	4·00
Belgium	4·00
Scandinavia	4·36
United States	2·65
Australasia	2·30

These figures are still more favourable when the fact of the large preponderance of males over females is made a feature of the comparison.

Australian distilleries only employ 178 hands, and rarely operate on the open market. Their output is used for blending with Scotch or Irish whiskeys.

The imports under the head of agricultural products, &c., are large, and mostly comprise tin goods, principally fish. All the States are food growing and of the main staples (bread, meat and fruit), Australia exports largely. The only competition in these lines comes from special manufactures, and their volume has had some impetus of late years by the discovery of the Western Australian goldfields, on which there has been a large consumption of preserved foods. In this State trade the oversea supply has, so far, competed on equal fiscal terms, but the Eastern States now have the advantage of a free market, while the oversea producer will have a barrier in the uniform Australian tariff. As the restless conditions of Australia life disappear, local trade in all these lines, except perhaps tinned fish, should come into the hands of home growers. As an instance, Victoria has quite recently got control of her own dried fruit trade in all respects except currants, and is extending her trade in the other States, and South Australia is following the same lead. In any circumstances, where the main staples of the food supply are grown so cheaply as in Australia, settled conditions of life must drive out competition except in lines where some special feature is looked for. In many cases the English articles have the preference, because from want of capital to obtain plant and want of experience there has been a roughness about Australian goods under this head which has raised prejudices against them. An increasing trade and internal competition is, however, gradually eliminating this roughness by demanding a more careful production. It is, moreover, difficult to believe that Australasia's increasing agricultural development will not lead not only to a control of the local market in the articles manufactured from agricultural products, including all farm and dairy produce, but to a large and extensive export trade.

Under this division are included the meat and dairy production of Australasia. It was New Zealand that first opened this trade in 1882 with a small shipment, which by 1892 had risen to £1,091,262, and in 1902 to £2,685,960. In Australia the trade has been checked by the want of cross-bred sheep and the British prejudice against merino mutton. The export from the whole of Australia during 1902 (a bad year owing to exceptional droughts) only totalled £2,214,921. Under this division, too, comes the dairy produce, and of these lines in 1901 Australia provided 6·70 and New Zealand 4·52 per cent. of the total imports into the United Kingdom; a joint supply of upwards of 11 per cent., which placed Australasia as the largest supplier after Denmark. The falling off in 1902 was due to drought, but should be restored now that normal seasons are being enjoyed. That Australasia can with such articles compete in the markets of the world, notwithstanding a journey of six weeks, gives some indication of what can be done when other portions of farm and agricultural produce are taken in hand and prepared for export; *e.g.*, cheese, bacon, biscuits, dried and preserved fruits.

Apparel and Textiles. — Industries of this class afford more employment than any other, there being about 55,000 hands engaged in factories. The use of machinery, however, is not so extensive as the number of hands employed would imply. The factories deal with wool, hats, slop clothing, and other such products.

Our importations of woollens amount to £1,458,735, although we are one of the greatest wool-producing centres of the world In woollen mills in Australasia some 3,500 hands are employed, about half of whom are in New Zealand. The consumption of wool in these mills is about seven million pounds, and the output comprises two and a-half million yards of tweeds and cloth; four and a-half million yards of flannel; 130,000 pairs of blankets and 34,000 rugs and shawls, of a total value of £360,000. New Zealand also has 1,700 hands employed in flax mills; in no other State has this industry been established. As Australasia exports £18,000,000

worth of wool per annum and imports part of that same wool again after a journey of 32,000 miles in the form of clothing, &c., to supply her wants, it is difficult to avoid the conclusion that the question of her taking possession of her home woollen trade with the exception of high-class goods of limited demand and special make can only be a question of time. The dregs of the gold fever and the effects of the opening up of new agricultural and pastoral lands is still in the blood of Australians, and the maufacture of woollens is only now being seriously faced. As a higher class machinery is fitted in the mills, and the system of running the mills by inexpert boards of directors is cut out, the home trade in woollens with the qualification named is bound to overtake the supply. At present the Australian manufacturer limits himself entirely to men's clothing, flannels, and blankets. No dress pieces are made. The home trade must be limited in such lines, as all wool materials must be made light to obtain a sale. Winter, except in colours and the putting away of the very light materials , does does not make much difference in general apparel except in some isolated, cold, mountainous parts. It would, however, be a mistake to take it for granted that cotton-growing is out of the question in Australia. There are vast areas suitable to the plant, and though the present tendency is to assume that labour conditions will make the industry unprofitable, the question is by no means determined, and the value of such a crop is so great in itself, and so much more so in connection with wool, that I firmly believe the near future will witness a most determined effort to make a success of cotton growing in the Commonwealth. The foreign trade in this line of apparel and textiles would be turned into British by a preferential tariff. The matter of the rate of the preferential tariff in the clothing trade would cause the bulk of Australians little concern.

Metals and Machinery.—Of our export trade, £50,777 is for agricultural machinery, and is one of the very few items where manufactured articles are exported; this export is due to special manufacture and patented rights. Works connected with the treatment of metals, manufacture of machinery, agricultural implements and railway rolling stock form, a large and growing class of industry. About 42,000 hands are employed at this work, and about £4,000,000 represent the value of the machinery in the factories, which turn out, amongst other things, railway locomotives and rolling stock, galvanised iron and wire, agricultural implements, mining plants and machinery, but, with the exception already mentioned, the output is to meet local demands, and all iron and steel used is imported. The local manufactures may be said to principally comprise very heavy foundry work, and goods for which sea carriage would be very expensive. In most cases where manufacturing successes have been made, it has been due to an understanding of special local conditions. A mine can be more cheaply equipped from an Australian foundry, because each mining field has its special requirements which are provided for by the local manufacturer; the same considerations apply to agriculture. "The Stripper" is an Australian machine, brought into being because in good seasons straw is a burden to the local farmer, and this machine cuts the heads and leaves the straw standing. Another machine, the McKay Harvester, designed on the Stripper principle, has built up an export trade to countries where agricultural conditions are similar to the Australian—chiefly South America, but as a rule the home trade in machinery may be taken to be the heavy foundry work and local specialities. As an instance of what is meant by special conditions, a small Victorian foundry has a large trade in picks with the Western Australian mines, because experience in the Victorian quartz mines had shown just where strength should be placed to get results. The pick was promptly copied by American competitors, but it was some time before any of the British travellers could get their firms to do so. It has, however, been copied by an English firm lately, after competition had made such advances that a change became vital if the trade was to be saved. Under this head the foreign competition against Great Britain is growing, chiefly from the United States of America, but also by means of a cheap cutting German trade. The trade now possessed by the foreigner would nearly all pass into British hands if a preference were imposed. The import from America of some of their main lines (*e.g.* electrical machinery) cannot be affected by local manufacture for very many years, and is therefore an open trade for oversea competition, and the margin is so small that almost any preference would give an advantage which would secure the trade. The American trade, however, in agricultural machinery will

steadily be overtaken by Australian makers because local conditions are specially catered for. As an instance, the McKay Harvester Works at Ballarat cannot supply the demand for their machines, and each machine supplied takes the place of an imported reaper and binder.

Oil, Soap, Candles, Glass, &c. — We have about 1,800 hands employed in manufacturing soap and candles and 1,200 employed in glass works. Of soap and candles the output for 1903 was about twenty-eight thousand tons and six hundred and ninety-nine thousand tons respectively. Our exports are mostly of raw products such as oil and tallow. The oil imports are mostly in specialties and the home trade in earthenware is limited to the rougher work, and the home glassware trade to the everyday bottle of commerce. Of late years American glass, cheaper and flimsier, but made in imitation of the better English glassware, has been largely sold, and this is no unusual thing in manufactures. If the appearance of British makes can be got without the quality, the more durable and better made British article is frequently driven out. One Yankee drummer opened up a trade in carpets by introducing a carpet of Axminster patterns and appearance, but of admittedly inferior quality. "Life's too short for their kind of quality," the Yankee explained, "Mine looks as well, costs less, and will last till you get tired of it!" He got his trade.

Wood, Wicker, and Cane Goods. — Our export is mostly of undressed timber. We have 23,000 people directly working in wood, but probably the most of the 5,000 people working in "Furniture, Bedding, and Upholstery" should be added. The furniture trade is practically a home trade, but it is in a large part Chinese labour. Though Australasia produces various kinds of wood, admirably adapted to the requirements of the furniture trade, it can hardly be said that the trade has attained a development equal to its opportunities. The peculiarity of the Chinese is that they concentrate themselves on an industry; they have done so on furniture, and have practically taken complete possession of it. It is impossible to get any knowledge as to wages paid in the trade, and Factory Acts are dead letters to them. European workers say they cut wages. The Chinese say that they get high wages. Perhaps the truth lies in this, that they did cut wages to squeeze the white workers out, but now they have control they demand good wages. This Chinese labour cannot further expand, and even as it is a "strike" by Chinese workers in Melbourne a year ago showed that the working Chinaman whose labour has always been under the control of the "companies," whose headquarters are mostly in Hong Kong, are now getting out of control. A working Chinese is a strong supporter of a white Australia. He finds it suits him. As one put it to me—"Plenty here. More Chinamen come not so much tucker!" "Tucker" is food. The Trades Hall could not put the sentiment better. The Immigration Restriction Act must bring white labour back into the trade without causing any conflict with the Chinese now here, as a Chinaman once free from "Company" control soon realises the market value of his work.

Jewellery and Fancy Goods.—Of the export trade, gold and silver bullion and precious stones are the main factors, the export of jewellery, properly so-called, being very small indeed. We have 1,200 people engaged in our own trade, but of these some, no doubt, are principally employed in the repairs of watches and clocks. The British trade is small, owing probably to the predominance of American watches and clocks. Australia is too new a country to require much quality in jewellery, provided something reasonably good and cheap can be got.

Leather and Rubber (boots and shoes, but not saddlery and harness).—There are 15,000 people engaged in the boot trade who, in 1903, turned out 9,000,000 pairs of boots and shoes, and 500,000 slippers. The boot and shoe trade is one of the growing trades of Australia. In some States the Australian trade holds the market, and since Federation it is expanding in other States. The import trade is in infants' shoes and in adult boots of very good quality. Curiously, the infants' shoes beat the local market because of their cheapness and flimsiness, whilst the adult high-class boot beats the local market because of its good quality. The boots in which the oversea market finds the least competition are of the Northampton class. Lately the Americans have made strong efforts to capture the trade by establishing sub-companies which open retail shops. The bulk of the boot and shoe trade is sure to come under Australian control, though it is doubtful whether the factories will trouble for some years to compete with the trade now coming from Great

Britain in higher qualities. A preferential tariff would decidedly snuff out the American and German competition in the same lines, and thus double the existing British trade. For the local manufacturer there is a very large opening in all sorts of leatherware, the tanning industry being well developed, and last year turning out nearly 1,200,000 hides and four and a-half million skins.

Vehicles.—Here again special knowledge of Australian conditions count. Practically all vehicles properly so-called are home-made, because each district has its own peculiarities. The type of farm waggon varies in different districts. Australians are quick to learn, and in farming districts where the roads are either heavy from dust or from mud the value of the "Boer outrigger" to help the pull of the shafts was quickly seen and adopted when the returned soldiers spoke of it. About 7,600 persons are employed in these factories.

Sugar.—The exports of Australian sugar amounted to £22,366. The cane is grown in Queensland and New South Wales, but though slightly increasing in Queensland is decreasing in New South Wales. In 1903 there were 131,733 acres under cultivation; of the cane grown 423,302 tons were grown by white labour receiving a bounty of £90,770, and 628,084 tons by black labour. The Federal Parliament provides for the payment of a bounty of £2 per ton on all sugar produced by white labour. In 1903, 26,061 acres were registered as cultivated by white labour; for 1904 the acreage registered has increased to 56,289 acres. The Australian grown sugar represents 54·2 per cent. of all sugar locally consumed; the value of the cane crop for 1903 being £787,000. Forty-eight mills are in active operation and the capital invested in sugar mills represents some two and a half millions of money. About 2,000 persons are employed in this work.

Musical Instruments.—We produce pianos, and have employed in this work about 260 hands. The British values are not traceable, but so far as pianos are concerned the imports are nearly all German. The Australian firm which employs nearly all the 260 engaged in this work has, since Federation, made special efforts to obtain the local trade; the factory is most admirably equipped and has adopted the newest methods and machinery, and shops for retail purposes have been opened in all the States. Should this venture succeed in its determination to capture the bulk of the Australian trade, it will not only afford a most striking instance of what the local manufacturer and workman can do against the finest products of European and American workshops, but it will encourage similar efforts in other directions.

Nature of Exports and Imports.

I do not propose to follow every class of manufacturing occupation, but will content myself with the manufactures referred to. Those manufactures will show the main heads under which the future of our manufacturing expansion will principally lie.

Of the exports from Australia, totalling £48,170,164, specie and bullion account for £19,123,958, and merchandise accounts for £29,046,206. The total exports of Australian produce, £27,700,000, is for merchandise, and £17,800,000 for specie and bullion. Of the exports of merchandise, wool accounts for £13,997,000; coal and coke for upwards of a million; leather, half a million; undressed timber, £700,000; oils, £225,000; meat, £1,780,000; and butter, £1,200,000; fruit, £375,000. These items represent about £20,000,000, and are not exclusive, but quite sufficient to show that the exports of Australia are almost entirely of primary productions. Of the remaining sum of seven millions odd, quite half could, I think, be traced to the same source. Of the exports of New Zealand, amounting to £15,010,378, meat export accounts for £3,300,000; gold for £2,000,000; grain for £530,000; gum for £631,000; hides and leather, £150,000; butter and cheese, £1,500,000; flax, £600,000; agricultural and pastoral products (n. o. e.), £850,000; tallow, £465,000; timber, £240,000; wool, £4,000,000. These items also are not exclusive, though representing £14,000,000 of a total export of £15,000,000.

The imports on the other hand are almost entirely manufactured goods. Australia imported £36,500,000 worth of merchandise made up as follows:—

Stimulants and narcotics nearly	£2,000,000
Sugar	1,087,000
Agricultural products and groceries	7,094,000
Apparel and textiles	8,838,000
Metals and machinery	7,384,000
Jewellery and fancy goods	2,051,169
Oils and paints	1,243,000
Earthenware, glass, &c.	705,313
Drugs and chemicals	931,000
Wood, wicker, &c.	1,234,000

Leather, &c.	890,000
Paper and stationery	1,505,000
Vehicles, musical instruments and miscellaneous	2,297,000
And free goods	626,000

The imports of New Zealand amounted to £12 788,675, and, broadly speaking, show the same results as those of Australia.

The exports of Australasia may therefore be classed as primary products; the imports as manufactured products. The volume of import trade is so large that to secure even a substantial portion of the local trade will give to the manufacturer full scope for his efforts at present and an ample reward in the event of success. The Australasian market is altogether out of proportion to the population as the people are both great producers and great spenders, and their demands offers a splendid field of operation to the man who with capital and experience determines to cast in his lot with the manufacturers of Australasia.

General.

The conditions of the trade insist upon a ready adaptability, a willingness to meet the demands of the purchaser and an appreciation of the fact that a consumer wants to buy new goods not the manufacturer's old plant. The productiveness of Australasia shows its wealth and resources; its imports show its special value as a consuming market, while its geographical position opens to it certain external markets which the oversea manufacturer can enter only after a long sea voyage. The last two years mark an epoch in Australasian manufactures, and the next ten will amply justify the hopes of those who believe in Australasia's industrial development. The country possesses the two main factors of success. She has first-class coal, and she has large deposits of rich iron ores. She has wool, and she also has large areas suitable for the growth of cotton. Australia exports to external countries about a million tons of coal, and New Zealand exports nearly 200,000 tons; the industry is old and well established, and the quality of the coal well known. Iron ore is widely spread throughout both countries, and during the ensuing or next following session of the Federal Parliament provision will almost certainly be made granting a substantial bonus on the production of iron and steel from Australian ores in accordance with a recommendation made by a Royal Commission which dealt exhaustively with the subject. Australia cannot be said to possess water-power available for extensive industrial purposes, but New Zealand has this power so well distributed that she would appear to offer ideal conditions for those manufactures to which water-power is essential. Tasmania also has special capabilities in this direction.

Tariff.

The tariff of the Commonwealth is a compromise between the need for revenue and the demand for Protection, and it is needless to say that the result is satisfactory neither to Free Trader—a rapidly diminishing factor—or Protectionist. The passage of the tariff through Parliament occupied a whole session, and until September, 1902, the manufacturing industry was in a state of uncertainty which paralysed all progress. The Commonwealth tariff is lighter than that of New Zealand; it is lower in its average burden of duties than that of any separate State except New South Wales and Western Australia, and in some lines has had an appreciable influence in checking manufacturing expansion and in increasing imports. Of the total imports, exclusive of narcotics, 31·7 per cent. are of free goods and the average rate of duty on dutiable goods other than narcotics and stimulants is 19·7 against a prior pre-Federal rate ranging from 36·2 to 21·8 in four States and 10·3 to 14·8 in two States. If the Commonwealth tariff be compared with the tariffs of America or Canada, the results would meet the approval of the Cobden Club as it would by comparison appear free trade.

Industrial Legislation.

I do not enter into a discussion of the various Acts of Parliament which apply in the various parts of Australasia, and are known as "Labour Legislation." The great majority of these Acts are merely the adoption of reforms long advocated by the advanced public men in England; they are a recognition of the fact that whatever the State cannot do there is at least a very wide field of usefulness in eliminating some of the inequalities which exist and tend to impair the full value of industrial effort. The Industrial Arbitration and Conciliation Act is by far the most important, because so far-reaching and so novel. The father of that legislation (Mr. Reeve) is, I believe, present, and is quite qualified and able to defend it, but time will be its best indication.

Though temporary difficulties may and do arise, the growing influence of this Act upon public opinion tends to make strikes so impossible that it has already forced the settlement of at least one industrial dispute around which clung so much feeling that the Act alone saved a long and disastrous strike. Employers are rapidly adapting themselves to the changed conditions; the Act is receiving from them less opposition as its working is better understood, and the objections now raised are more due to the frequency with which the Act is invoked, and the too marked presence of industrial busy bodies than to any hostility to the Act itself. Most of the complaints to-day are almost inseparable from the first few years' working of so far reaching a piece of legislation, but those who appreciate how great are the issues involved, and how incalculable a blessing the success of this Act will be, should it replace strikes by arbitration, will watch its operation with sympathy and patience.

TRADE WITH THE MOTHER COUNTRY.

The conception of Empire as a division of labour in which the outposts shall remain primary producers of raw products and the Mother Country the sole centre of manufacturing industry is not one which commends itself to Australasians and the colonising spirit which made the Empire by its attachment to locality manifests itself in a determination to make the new home as complete and self-sufficient as is possible. In the prosecution of this aim there is nothing antagonistic or exclusive of mutual trade preferences; it is indeed but an application in detail of the wider principle. When the Empire, as a whole, is felt to belong to and to appeal to all as closely as Australasia appeals to its people, the adoption of imperial trade preferences will be but an extension of the principle which, at present, actuates Canadians and Australasians in their determination to encourage local developments. I offer no apology, therefore, for stating that though an ardent supporter of preferential trade, I am a strong believer in the need to re-adjust our Commonwealth tariff on lines more favourable to the local manufacturer. That action in this direction will soon be taken is apparent. A Commission has been appointed and is now sitting to consider the question of tariff amendment, and most probably Parliament will deal with the matter at its next session, and grant to the local manufacturer a more adequate protection than he now enjoys. Even then we are not likely to see a tariff with walls so high as those which surround America.

The trade of Great Britain with Australasia is proportionately less than formerly; the imports are now about one-third foreign as against one-fourth ten years ago. The exports show a somewhat similar trend. This is not all due to causes which the British manufacturer can prevent but those preventible causes account for a substantial part of this relative retrogression and the result is deplored by Australians more keenly apparently than by Englishmen; a fact which may be explained by the evidences of foreign encroachment being more manifest in Australia than in England where Australasian figures get lost in the huge totals of all trades. The Australasian deplores these inroads upon the commerce of the Mother Country just as he would feel—though of course in a greater degree—any military or naval reverse which affected her. The commerce and trade of England help to form that prestige in which all who belong to her Empire take such pride. In these days it is in the peaceful warfare of industry and commerce that are manifested the brains and energising power of a civilised people, and Australasians are too deeply attached to the Mother Country, too proud of the Empire's greatness to feel aught but regret at industrial or commercial retrogression which is none the less substantial because relative rather than absolute. It is from such motives that the desire for trade preference so largely springs. That a change so great implies the risk of failure may be admitted. Such consequences have to be faced by every individual and by every community to whom advance is vital. But a readiness to work together and a united effort to discover a satisfactory line of advance will go so far to minimise the chances of failure that nothing but the mere fear which always stands in the path of progress will allow possible risks to overshadow most probable gains. Believing, as we so largely do, that mutual concessions can accomplish so much to secure for the Empire the control of its own trade and the enormous expansion of its varied resources, it is not to be wondered at that Australasians almost unanimously desire to see an earnest attempt made to arrive at a scheme upon lines satisfactory to the moderate men on both sides without asking the acceptance of details. We are at a loss to understand why the very thought or suggestion of such a scheme should in England be regarded with such bitter opposition and resentment, that any attempt to

meet together and discuss the matter is anathematised by bell, book, and candle. Under the present Australian tariff, and in relation to the present Australian trade, there is room to divert to Great Britain many millions of imports which now come to us from foreign countries. Whatever tariff is adopted—and no great departures from our present tariff are immediately probable—there will always be a large and growing import trade which preference can affect. The growth of Australasia as a consuming market is bound to increase though the class of imports may differ. Whether therefore the position be judged by the existing tariff and available trade of to-day, or the probable tariff and increased trade of ten or twenty years hence, Australasia offers to the British manufacturer a market well worth having. Whether preferential trade by securing that advantage entails other and greater losses is the only question worth consideration. That question can never be settled when approached as if fiscal treason were involved in its mere expression. Our race has not yet been a slave to the adoration of any theory (though in England it goes perilously near to fiscal fetichism); it does not concern itself with a vain effort to attain logical perfection; it loves and boasts of its preference for the practical solution of difficulties by the application of common sense. To deal with this question there is only one common-sense method; that is, to meet together with an anxious desire to serve the Empire as a whole and a willingness to act in co-operation should a full consideration show the need for readjustment. There never was an occasion on which appeals to prejudice and party interests were more to be condemned; there never was a question which should more commend itself to both parties as one deserving a careful and sympathetic inquiry. Should such an inquiry be granted, those of us who believe that a readjustment of the commercial relations of the communities of the Empire will lead to a more lasting and more real union of that Empire are confident as to the result. We merely ask that we shall not be condemned without trial merely because our contentions may not exactly square with what was laid down fifty years ago for the guidance of commerce under conditions as primitive and simple in relation to the vast and complex system of to-day as is the first Atlantic steamer when compared with the most recent ocean liner.

A.—WAGES PAID IN MANUFACTORIES TO EMPLOYEES (MALES).

The figures are given as far as data is available.

Industry.	Average weekly wages.—Males. New South Wales.	Victoria.	Queensland (Brisbane).	New Zealand.

DISCUSSION.

The CHAIRMAN was sure that all had listened with very great pleasure to the paper. The author had the pen of a ready writer, but he had still more markedly the tongue of an eloquent speaker. He had properly laid stress on the enormous difficulties due to distance which Australia had to combat. The public of this country, however, were very much better informed on that subject than they used to be. They all knew the story of a young bishop who contemplated going out to Perth, and who, not being very experienced in the wielding of the crook, was told by a friend that there was a most experienced prelate in Adelaide, and if he had any difficulty, all he had to do was just to step across and consult him. There was also the story of the Commandant in Tasmania who received orders to march his regiment by easy stages to Sydney. But the geography of the Empire was better understood now on both sides. The author spoke perfectly truthfully when he said that Australian manufactures were still in their infancy. He also thought that the idea of Australians remaining merely primary producers had disappeared. They did not want the British Empire to be composed of sections of nations scattered in various quarters of the globe. That Imperial federation to which they looked forward would be impossible if the colonies which had sprung from the Mother Country were not equipped and furnished with all necessities for full national life. The author had pointed out that per head the Commonwealth produced more from primary industries than any other country, the figures being £21 12s. 9d. in Australia, as compared with £7 18s. 6d. in this country. Doubtless they remembered the saying in a British colony where the only industries were those of canning and preserving their natural produce, "Eat what you can, and can what you can't," but they wanted the industries of Australia and of every portion of the British Empire to extend far beyond those of elementary production. He thought the author was on sound lines when he claimed that the Federation of Australia had presented a magnificent opportunity for the advancing of Australian manufactures. Why was that the case? It was simply because the Federation of Australia was the consummation of a great free trade movement by the adoption of a tariff. Under the Federation the Custom-houses on the various borders were abolished, and every manufacturer had the advantage of the market of adjoining States. How was this free trade within the continent of Australia achieved? The pathway to free trade lay through the territory of protection. It was when the other States followed the example of Victoria and erected fiscal barriers on their borders that the cry arose for the abolition of those barriers; if all the States had been content to see Victoria continue her protectionist policy whilst they themselves admitted her goods free, there would not have been free trade throughout Australia at the present time. They all desired free trade, and if free trade would not come to them, they would have to go to free trade; and even though it was necessary to approach that ideal through tariff reform that was no reason why they should not advance in the pursuit of it. The author had alluded to the Australian workman. He (the Chairman) had himself come to the conclusion, after seeing labour in many parts of the world, that there was no labour so cheap, taking into consideration efficiency, as that of the Australian worker. He was alert, bright, and active, and in advancing the manufactures of Australia there was most excellent material provided, not only by nature but also in the shape of willing, capable, and efficient labourers. The manufactures of Greater Britain were not built up by orthodox methods; in Canada the heretics carried the day, and the same remark applied to Australia. It would surprise those who still adhered to the methods of the old school to know to what extent bounties and State-aid had ministered to the development of Canadian and Australian industries. As a matter of fact, the origin of manufactures in both those countries dated back practically to the departure from the shibboleths of the *laissez-faire* school. They were on the search for knowledge in Australia, and, having what might be called a well-balanced prejudicial mind on the question of tariffs, they would like to hear of any great industry that was rooted in free trade. He knew of none. The tariff of Australia was very limited as compared with other countries, and he would say to the manufacturers of Great Britain that now was the accepted time to join reciprocal hands with Australia, as the opportunity might not occur again so favourably when the tariff walls were built up higher.

MR. C. C. LANCE (Commercial Agent for the Government of New South Wales) said the author had displayed great ability in dealing with the subject, but he would like to make mention of one small matter in regard to the frozen meat trade. He said it was inaugurated by New Zealand in 1882, whereas the first ship that brought frozen meat across the world was the *Strathleven*, which was loaded in Sydney and Melbourne in 1880. But that fact did not at all detract from the credit due to New Zealand for the way in which it had developed its frozen meat trade. The Chairman had mentioned the question of bounties in developing industries, and it occurred to him to mention of what great value bounties had been to the butter industry. The butter bounty originated in Victoria, bonuses being given for the erection of factories and for all butter sent to this country that realised a certain price. The bonus amounted to 3d. per lb. in the first instance, but had gradually been discontinued. Factories arose everywhere throughout the country, and in the course of two or three years a great industry was built up, which, without bounties, would have taken much longer to develop.

Sir M. M. BHOWNAGGREE, K.C.I.E., M.P., joined with the Chairman in the very deserved commendation passed upon the paper and its author, and heartily congratulated Australasia upon the exceedingly prosperous condition of affairs with regard to its industries. A comparative table was given in the paper with regard to the temperance of the Australian people as compared with the people of other civilised nations, and, if the figures referred only to the white population, he thought that formed an additional subject for congratulation. With regard to wages, if the rate was higher in Australia than America, and living cheaper in Australia than America, then the condition of the Australian working man was very flourishing indeed. But if the condition of the Australian working man was so extraordinarily flourishing, why did he want to keep out labour from other parts of the Empire? If any body of working men from the Empire of India wished to enter Australia a great number of difficulties were thrown in their way. He granted that when bands of emigrants had gone out from the Mother Country in search of a mere sustenance and the necessaries of life, they had a prime right to keep for themselves the colony which their labour and sacrifices had established; but what he complained of was that form of competition and prejudice which kept out the British Lascar. He did not think it conducive to the further cementing together of the British Empire for Australia to refuse, against the advice of such an Imperial statesman as Mr. Chamberlain, to enter into a postal contract in order that its shores might not be "polluted" by any ships upon which Lascar seamen were employed. He spoke in the presence of influential colonists and of his esteemed friend, Sir John Cockburn, than whom he did not know a better Imperialist and friend of the Empire, and he asked if it was not time, when at meetings like the present they were talking so much about the unity of the British Empire, that these gentlemen should denounce restrictions that were creating irritation among 300 millions of people. He did not think he would be doing his duty as a citizen of Imperial Britain if, when he happened to be present in a room where the subject of Imperial unity was being discussed, he did not point out that great defect which had been made manifest in many ways in the policy of the Australian Commonwealth.

Mr. H. ALLERDALE GRAINGER (Agent-General for South Australia) thought the views which the last speaker had expressed would commend themselves to any body of Australians. But they had found out that people, whether they came from India or China or elsewhere, were apt to cut out the Australian workman by working longer hours for less wages. Australians were not all of one mind on the subject of the refusal to make mail contracts with steamers employing black labour. They were not allowed to enter into such a contract by an Act carried in the Federal Parliament with the support of Sir Edmund Barton, Mr. Reid, and others. He thought it was a very foolish thing indeed, but the majority had it their own way. With regard to the author's reference to the exports and imports, he thought it was misleading to talk about the imports in Australia being so much less, without reference being made to the fact that Australia was unable to borrow money on good terms in England. When they did begin to extend their railways, the imports would mount up by the million. When anybody referred to the figures of exports and imports they ought to go very carefully into the details, and point out where the falling off in those imports had been. He was a Protectionist himself, but he admitted that the Free Traders had strong arguments on their side; in fact, he went a great deal further than some of them so far as Australia was concerned. Australia had to look after its own commercial interests to the best of its ability. One did not give trade to one's relations if they charged more than anybody else, and if Australia by entering into an agreement with other nations could make money over it, he would vote in favour of that policy, whether he was considered patriotic or otherwise.

Mr. JAMES, in reply, said he was at a loss to understand why any suggestion which involved commercial co-operation, such as preferential trade, should necessarily imply either political or social co operation. He did not think the question to which reference had been made by Sir M. Bhownaggree was relevant to the subject. It was a very important question, and too long and contentious to discuss now, but he assured his hearers that it was an entire misconception to say that legislation in that respect was based upon any selfish desire to protect the Australian working man from competition; it was founded on deeper and broader convictions than that. He wanted to dissociate himself entirely from Mr. Grainger in reference to the mail service; it had nothing whatever to do with discussing the question of Australian manufactures, and he regretted the question had cropped up. Mr. Grainger had also said that he should have examined his figures in greater detail. The last words in the paper were words of apology for the time he had taken up, and he asked the audience whether they would have approved of his taking up additional time in the closer analysis of the figures of one year's returns. No one could deal with the question in a short paper. Figures, of course, could be made to prove anything, but the fact remained that the output of manufactures was increasing, and anyone could see in Australia many evidences of the increased development of Australian manufactures.

On the motion of the CHAIRMAN, a hearty vote of thanks was accorded to Mr. James for his valuable paper.

COMPENSATION FOR INJURIES TO WORKMEN.

There has just been issued a memorandum on the laws of foreign countries and of British possessions relating to the rights of workmen to compensation for injuries by accidents occurring in the course of their occupation. This memorandum has been drawn up by Sir Kenelm Digby, as Chairman of the Committee on Foreign and Colonial Laws relating to Compensation for Injuries to Workmen. It is hoped that on another occasion space will allow of a more extended reference to this very valuable State paper, but in this issue of the *Journal* note is taken of the law as it stands in the only great country which has not as yet in any form adopted the principle of workmen's compensation for accident without proof of any default, namely, the United States. In all the principal European countries the laws relating to the subject seem to have passed through similar stages. In the earlier part of the nineteenth century the workman had no special claim to redress from his employer for injury from accident. His right was the same, neither more nor less, as that of anyone else who had the right to claim compensation from a person responsible for causing an injury, that is to say, the workman, in order to recover damages for an injury, had to prove a default on the part of the employer himself, or of some person for whom he was responsible. But the vast advance made during the past century in the magnitude and complication of industrial enterprises, the establishment and extension of railways and of machinery moved by steam power, and the increase in the number of industrial accidents with which the advance was attended, induced every European Government to review its laws providing compensation for injuries by accident, with the object of improving the position of the workman and enabling him to obtain more adequate redress. It is only in the United States that the workman remains where he was in the matter of compensation for injuries by accidents occurring in the course of his employment.

The law varies to a considerable extent in different States of the Union, but in all it is grounded on the English Common Law. The doctrine, however, of "common employment" does not appear to be, says Sir Kenelm Digby, recognised to the same extent as in England. Nor is the view taken of the extent of the doctrine uniform throughout the various States. "While the general law is stated to be that the workman takes upon himself all risks resulting from the negligence of his fellow servants, this rule does not apply to the agents of the employer to whom he has delegated his own authority, and there have been wide differences in the various States as to the persons who are and who are not to be regarded as fellow servants. Several States have adopted modifications of the Common Law in the direction of increasing the liability of the employer for the negligence of a fellow servant, chiefly in the case of employment on railways, and some have passed laws extending similar principles to other industries. But no State has gone the length of enacting any law imposing upon the employer any duty to contribute to the relief of workmen from the consequences of accidents not proved to have been caused by the default of the employer himself, or of some person for whom he is responsible." In this state of things it is surprising to find that the rates of assurance against employers' liability are, in the experience of the leading English companies doing business in America, "Very much higher than the rates for liability in this country, both under the Employers' Liability Act of 1880 and the Workmen's Compensation Act of 1897." The explanation is to be found in the heavy verdicts which American juries give in the cases which in fact are brought into the courts.

In 1903 the Governor of Massachusetts appointed a committee to report on the relations of employer and employee, and in their report, dated January, 1904, the committee dealt with the question of workmen's compensation. They referred to the Bills bearing on the question, no less than three of which had been introduced into the last State Legislature, and reviewed the State law as to remedies for industrial accidents. The committee dwelt on the dissatisfaction felt with the existing state of the law—both by employers and employed—the employers complaining of the growing burdens of litigation and of the tendency of juries "to increase their burdens by awarding liberal verdicts against them." The workmen complained that under existing conditions injured employees did not receive "a fair and certain compensation for their injuries." They complained also of the delays in the courts; that they were forced to fight "not their employers but unsympathetic employers' liability insurance companies, with their corps of claim agents, experts, and attorneys." "It is further claimed that the injured employee, if after a long time he is successful in recovering damages, receives in the end but a small part of the sum so recovered, owing to the expenses of litigation, and the exorbitant and unreasonable charges of his lawyer and medical adviser." To remedy this state of things the committee drafted a Bill closely following the English Compensation Act of 1897—even adopting some of its proved defects—with, however, some important variations. The most important of these is that the proposed interval between the accident and the commencement of the compensation shall be one week and not two. A more effective obligation to elect between the remedies open to the workman is provided, and a careful provision is made, somewhat differing from our law, as to the vexed question of "sub-contracting," and "workshops" are included as well as factories. A measure based upon the Report of the Committee was introduced into the Massachusetts Legislature last year, but not carried. It has been again introduced in the present Session, but has still to become law. As yet no American State has passed an Act of the kind.

THE TECHNICAL SIDE OF EDUCATION IN THE WEST INDIES.

There has recently been issued by the Board of Education volume 12 of the "Special Reports on Educational Subjects" (Cd. 2377),* which deals with the educational systems in the West Indies, Central America, St. Helena, and Gibraltar. The history of education in each colony or possession is given, together with a description of the present state of education, and copies of various legislative enactments and syllabuses of study. Generally speaking, doubts may be entertained as to whether the type of education afforded is that best suited for the needs of the case. For instance, in the Bahamas, where special attention is given to the teaching of sewing to girls, it is stated that "none of the boys reached by the Education Act proceed with their studies after leaving school." The demand for clerks in the Government service or in stores is extremely limited and poorly remunerated, while there is a dearth of artizans. "At present there is not one master carpenter, blacksmith, or mason in the colony, and no means of training these." A system based upon the industrial training methods in Tuskegee, in Alabama is, therefore, advocated. Barbados and Bermuda also possess no technical or industrial schools. In British Honduras, commercial instruction is given at one of the colleges, and the establishment of a botanical station for the purpose of affording practical information to persons interested in agriculture is contemplated. In Trinidad agriculture has been added to the subjects of instruction in the elementary schools, and school gardens are becoming the general rule. A committee has also been appointed to consider the question of systematic technical education. In Grenada no manual training or instruction in handicraft is provided. Sewing and domestic economy is taught in the elementary schools, while the teaching of agriculture is provided for pupils in the higher standards. The teaching of this subject is rather hampered by the lack of suitable plots. St. Lucia possesses an agricultural school, conducted on an abandoned sugar estate. In addition to the providing of a general education, the chief aim of the school is to train "practical agriculturalists in the full sense of the words, not only by teaching them to handle hoe and cutlass, and by putting them to such manual labour as their strength allows, but also by giving them all the necessary instructions in the sciences allied with agriculture." St. Vincent possesses a similar school.

One of the most readable parts of this publication is an appendix written by the Bishop of Jamaica on education in that island in relation to skilled handicraft and agricultural work. It is certainly surprising to read that in this respect the present position in the island is actually inferior to that in vogue during the slavery days, when "there was on the estates practically a universal system for training a regular succession of masons, carpenters, blacksmiths, coopers, and workers in similar trades. Frequently artizans were brought out from England to become the head men in these departments, and in other instances native workmen were quite competent to instruct those put under them, and so hand on to the next generation the secrets of their trades." A diminution in the numbers of skilled artisans has, therefore, taken place, as has also occurred in the southern States of the Union. As regards agriculture, the negro population of Jamaica may be considered expert in the cultivation of the sugar-cane, coffee, yams, cocoa, sweet potatoes, and the like, except in so far as modern scientific knowledge requires to be applied to these cultivations. "But as regards the numerous other products that need to be cultivated in the place of the doubtful and failing industries, the black people have everything to learn."

The following represents the course of tuition in agriculture as now afforded in the various schools. In the elementary schools there are three divisions for this subject. In the lower division a course of thirty-six lessons is given in animal and plant life, dwelling especially on the animals and plants found in Jamaica. In the middle and upper divisions more advanced general science is taught, and also more agricultural science, including the formation of soils, plant food, manures, and common objects of cultivation in Jamaica. An advanced course is also provided in certain schools. This is a practical application in out-door experiments of the knowledge obtained in the schools. An experiment ground of not less than a quarter of an acre must be provided in which every boy above eleven years of age must be taught practical skill in all agricultural operations. The extensive introduction of the advanced course is at present restricted on account of a lack of properly trained teachers. These latter undergo a special three years' course of preparation at the Mico College. Detailed information on this matter, as well as a review of the special schools now in existence in Jamaica, will be found in the appendix, which at once affords a clear statement of present facilities for, and a sympathetic treatment of, the problems of the mental, manual, and moral uplifting of the negro race in the West Indies.

AUSTRALIAN TOBACCO.*

A considerable portion of the Australian Commonwealth, an area of at least several thousand acres is, like many of the lands in the American southern States, admirably adapted for tobacco cultivation, although the industry, after years of experimental labour, is yet in its infancy, Americans visiting Australia expressing surprise at the limited attention it

* Communicated by Mr. John Plummer, Sydney, New South Wales.

has received in many places. In New South Wales, we are told, the systematic cultivation of tobacco dates from 1874, in which year it was introduced by three Chinese settlers, who produced within a few months a sufficiency of cured leaf to bring them £180, the Sydney selling price being 6d. per pound. Four years later the prices rose to 8d. and 9d. per pound. In 1880 the area under cultivation in the Tumut district was 1,400 acres, on which 400 Chinese were employed. Two years later the price dropped to 5½d. per pound than to 5d., and, finally to 4½d., at which it did not pay the growers. Recently the rise of keen competition in the Australian tobacco manufacture has occasioned a demand for locally-grown leaf. The State Government has fully recognised the importance of encouraging the tobacco-growing industry by establishing a couple of plantations, in which the practicability of obtaining a first-class article has been clearly shown. Yet, notwithstanding this encouraging result, the area under cultivation in the State during 1903-4 was only 407 acres, the production being 5,220 cwt. of leaf. In 1888, 4,883 acres were under cultivation, producing 55,478 cwt. of leaf, but there was no over-sea market for it, and growers became discouraged. It was much the same in Victoria, where the area under tobacco in 1903 was 129 acres, against 2,029 acres in 1905, and in Queensland, where the area in the same year was 772 acres, against 1,061 acres in 1895. The cause of this decline is readily explained. The leaf had not, save by way of experiment, been prepared in such a manner as to find a sale in over-sea markets. Much of the curing has been done in a somewhat primitive fashion, Australian farmers too frequently imitating the crude methods of the Chinese growers, who aim at quantity rather than quality. What can be done in the right direction is shown by the fact that, at the close of 1903, a number of test samples of manufactured tobacco, from leaf grown at the Victorian State tobacco farm at Edi, were prepared by the manager of an Australian tobacco company, who expressed himself pleased with them generally. The cigar varieties of leaf were handed over to another tobacco manufacturing company, the manager of which, reporting to the Victorian Minister for Agriculture, spoke favourably of them, that they were the best samples of Australian-grown cigar leaf ever submitted to him. All the leading importers in Melbourne spoke favourably of the samples submitted, and it was fully demonstrated that if due attention be given to the details of cultivation and curing, tobacco can be as successfully grown as any other agricultural crop in the Commonwealth. In Queensland the tobacco-growing area is somewhat extensive, the cultivated portions being found chiefly in the southern part of the State, west of the Great Dividing Range. Tobacco has been successfully grown as far north as the Herbert River, also in the Mackay and Cairns districts; and it is believed that in the near future tobacco cultivation, notwithstanding fluctuations in production occasioned by unfavourable climatic and other conditions, will become one of the staple industries of the State. The Queensland Secretary for Agriculture, in his annual report for 1902-3, says, that the possibility of a successful growth of the tobacco plant has never been in dispute, nor has the cultivation of it passed the ability of the farmer who understands his work. The sole difficulty has been the imperfect curing of the leaf. At the State tobacco farm at Texas a couple of tons of tobacco were raised, notwithstanding the absence of rain, which, when cured, realised 11d. per lb. at public auction, the highest price yet obtained in Queensland under similar conditions. Small quantities of tobacco are grown in South Australia and Western Australia, where there are extensive tracts suitable for the purpose, but at present remaining unutilised. In fact, it is believed that the Australian area capable of producing commercially valuable tobacco is larger than that found in the American southern States. The quantity of unmanufactured tobacco imported into the Commonwealth during 1903 was 5,156,793 lbs., value £232,884, of which 4,998,969 lbs., value £224,961, came from the United States. If Australian tobacco growers could supply sufficiently large supplies of leaf equal to that imported, they would readily become absorbed in the local market. What is required is experience and capital. With these combined, tobacco cultivation would speedily become a highly-remunerative Australian industry.

SPIDER-SPUN SILK.

A good deal of interest has been aroused as to the practical uses to which the webs of a large Madagascar spider might be applied to replace silk for woven fabrics, and the United States Consul at Tamatave calls attention to webs which he has noticed in his visits to the interior, spun many feet across the walks or shady avenues of gardens, which are sufficiently strong to bear the weight of a light bamboo walking-cane. At the Paris Exposition of 1900, a whole piece of fabric, 18 yards long and 18 inches wide, was exhibited, which was woven out of this web, for which it was necessary to provide 100,000 yards of spun thread of 24 strands. For its manufacture 25,000 spiders had to be brought into requisition, and these were procured by offering the natives so much a hundred; but, not knowing or ignoring the purposes for which the insects were required, they brought them in by the basketful, mostly dead. So it was found necessary for the winding-off machines to go to the spiders, instead of calling in the spiders to the winders. However, the piece of cloth was completed, and was of a golden yellow colour. The idea of obtaining silk from the spider is an old one, as the subject was discussed in France as long ago as 1710, but the study of this Madagascar spider came more particularly under notice some seven or eight years ago,

and the spinning of its web was then undertaken. It is only the female that spins. The first difficulty in securing the thread direct from the insect consisted in contriving how to secure the living spider so as to wind off, by some mechanical process, from the insect. This was originally performed by confining the spiders in empty match-boxes with the abdomen protruding, which could be compared to so many reels, from which the threads is wound off. The extraction of the web does not, apparently, inconvenience the insects, although care has to be taken not to injure them. From that stage was derived a frame of twenty-four small guillotines, in each of which a spider is secured in such a manner that on on one side protrudes the abdomen, while on the other head, thorax, and legs are free. This precaution of keeping the legs out of the way is necessary, because the spiders, when their secretions are spun off in this fashion, are liable to break off the web with their legs. It appears in the opinion of many to be an established fact that the Madagascar spider's web is capable of being woven into cloth which might warrant its cultivation for purposes of textile industry. The idea of using cobwebs as a hemostatic was known to the Greeks and Romans, and before the present antiseptics were brought into use by medical science, they were in general use for stopping the flow of blood from wounds and cuts. From an industrial point of view, the silk of the spinning spider has, it is said, been known for centuries, even by the savages of Paraguay, and in the seventeenth century Alcide d'Orbigny ordered in South America a garment of this material. There is in existence in Venezuela a spinning spider, found in the palm-trees there, some of which produce white and others yellow silk. The entomologist of the United States Department of Agriculture has reported that silk produced in this way cannot be made valuable commercially because of the troublesome necessity of keeping the spiders separated to prevent their devouring each other. The entomologist added that attempts to utilise the silk of a Madagascar spider of the same species as the Venezuelan variety resulted some years ago in the discovery that the product was more expensive than ordinary silk. The Madagascar spider is the *Nephila Madagascariensis*, and combines all the characteristics of Arachnida in general. Its bite is not dangerous, although the irritation caused by its legs is annoying. The egg which produces the spider is laid by the female is a silky cocoon one inch in diameter, of a yellow colour at first, but turning white after an exposure of two or three months to the air, at the end of which time several hundred insects, the size of a pin-head, burst the shell and come out. Three months later the female is two and a half inches long, while the male remains only one-sixth of that size. The spiders are carnivorous, and by preference frequent the forests. In some of the wooded gardens in the suburbs of the capital of Madagascar, especially the old royal parks, they may be seen in millions, and would give the impression of being gregarious, but this is not so, it being the abundance of food which brings them together in seeming peace and amity, but as soon as the supply fails, they fight and devour each other. In the early attempts to rear them, two hundred were placed in a wire cloth case; they spun their webs over the walls of their prison until it was so completely covered, that no mosquitos or other insects could get in. Thus deprived of food, on the principle of the survival of the fittest, the stronger went on devouring the weaker until only a few were taken out alive, but these had attained an enormous size. This spider is little disposed to migrate from its abode, and submits without resistance to manipulation. The first experiments in Madagascar were due to a Catholic missionary, and his experience proved that after the laying period, or formation of the web, it can be reeled off five or six times in the course of a month, after which the spider dies, having yielded about 4,000 yards. Native girls do the work. Each one has a straw basket at her side every morning filled with live spiders, and another basket to receive them after they have been wound off. One dozen are locked in at a time, the ends of their webs are drawn out, collected into one thread which is passed over a metal hook, and the reel is set in motion by a pedal So soon as the insect gives out no more web, it is replaced without stopping the wheel, and, later on, carried back to the park, where it requires nine or ten days before being ready for a second operation. The cost of this silk web is high; 55,000 yards of 19 strands in thickness weigh only 386 grains, which, calculating the time and labour of procuring and preparing it, brought it up to £8 per pound.

GENERAL NOTES.

Coal Industry of the United States.—Mr. E. Seymour Bell's report on the coal industry of the United States (No. 631, Miscellaneous Series) shows that the total production of coal in the United States in 1903 was the largest on record. It amounted to 319,068,228 tons, valued at 503,724,381 dols., and exceeded that of 1902 by 50,000,000 tons. The prices, too, for both anthracite and bituminous coal, reached the highest point recorded in a period of 24 years, the average of the one being 2·28 dols. per ton, and of the other 1·39 dols. Anthracite coal is produced almost exclusively in the State of Pennsylvania, only small quantities, not amounting to 100,000 tons per annum, being found in Colorado and New Mexico. Bituminous coal is found in almost every State of the Union, and extends over an area of 300,000 square miles. Of the coal exported from the United States in 1903, no less than 79 per

cent. went to the Dominion, and of the rest 10 per cent. went to Mexico and 8 to the West Indies. The output of coal in Pennsylvania is increasing with great rapidity. Anthracite has risen from 23,437,500 tons in 1876-80 to 54,598,908 tons in 1901-3 (3 years); bituminous in the same period from 31,830,357 tons to no less than 228,807,839 tons. Taking the average prices of the year, they were highest in Idaho—3·47 dols. per ton—California being next with 3·20 dols. The lowest was 1·08 dols. in Virginia, the next being 1·19 dols. in Kentucky.

TECHNICAL EDUCATION IN BURMA.—In connection with the Engineering School at Indis, it is proposed that the present qualification for joining which consists in passing an entrance examination, should be replaced by a probationary period of six months devoted to technical training. It is anticipated that this change will improve the status of those who pass from this school into the subordinate grades of the Public Works Department. Ultimately, if a sufficient number of students offer themselves, it is proposed to raise the status and curriculum at Insein to that of the engineering colleges of Roorkee and Sibpore.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

MAY 3.—"Recent Excavations in Rome." By MRS. BURTON-BROWN.

MAY 10.—The Native Races of the Unknown Heart of Central Africa." By LORD VISCOUNT MOUNTMORRES.

MAY 17.—"The Use of Wood Pulp for Paper Making." By S. CHARLES PHILLIPS, M.S.C.I.

MAY 24.—"Modern Lightning Conductors." By KILLINGWORTH HEDGES, M.Inst.C.E., Hon. Sec. to the Lightning Research Committee.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

MAY 11.—"The Manufactures of Greater Britain. —III. India." By HENRY JOHN TOZER, M.A.

MAY 18.—"Plague in India." By CHARLES CREIGHTON, M.D.

COLONIAL SECTION.

Tuesday afternoons at 4.30 o'clock:—

MAY 23.—"The Cape to Cairo Railway." By SIR CHARLES H. T. METCALFE, Bart., M.Inst.C.E.

APPLIED ART SECTION.

Tuesdays, at 4.30 or 8 o'clock:—

MAY 2, 4.30 p.m.—"The Monumental Treatment of Bronze." By J. STARKIE GARDNER. SIR GEORGE BIRDWOOD, K.C.I.E., C.S.I., will preside.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

ALAN S. COLE, C.B., "Some Aspects of Ancient and Modern Embroidery." Two Lectures.

LECTURE I.—MAY 1.—Application of the term embroidery to methods of working ornamentally with threads—Specimen of Egyptian embroidery, 1450 B.C.—Correspondence of its method with that of much Greek and Roman embroidery—Embroidery as an occupation in Greek houses, and as a trade in Rome—Embroidery in Benedictine monasteries and convents—The relation of illuminations in MSS. to designs for embroideries—The Dalmatic of Charlemagne, and suggestions of its figure designs being derived from Frankish illuminations of the 9th century—Comparison of designs for Bayeux tapestry, with outline figure drawings in MS. of Ælfric's Pentateuch.

LECTURE II.—MAY 8.—Embroidery in England, 12th and 13th centuries—MS. illumination, painting and embroidery as secular arts in 13th and 14th centuries—Influence of work in one art craft (the Goldsmiths') on that in another (Embroiderers')—Types of ecclesiastical English embroidery 13th, 14th, and 15th centuries, compared with contemporary illuminations in MSS. — Designs for English embroidery gradually affected by developments in ornamental weaving abroad—Symmetrical and floral patterns taking the place of designs with figure subjects having an epical or story-telling interest—English secular embroidery of the 16th and 17th centuries — The "conceits" in embroidery of the Elizabethan and Stuart periods—Embroidery in costume in 16th, 17th, and 18th centuries—Aspects of modern English embroidery—the designs for it: different phases of its practice, for ordinary trading purposes, for more limited purposes, and for specia occasions in connection with technical instruction—Embroidery.

HENRY WILLOCK RAVENSHAW, Assoc. M.Inst.C.E., Mem.Fed.Inst.Min.Eng., "The Uses of Electricity in Mines." Two Lectures.

LECTURE I.—MAY 15.—*Application of Electricity and Character of Load.* — Winding—Haulage—Pumping—Coal cutting—Other uses underground—Surface requirements—Generating stations—Cables and distribution — Lighting — Signals — Telephones—Shot firing.

LECTURE II.—MAY 22.—Alternating and direct currents — Precautions — Enclosed motors — Home Office rules—Costs—Typical and historical plants described.

The lectures will be illustrated by lantern slides.

MEETING ON THURSDAY, APRIL 27...Electrical Engineers, Great George-street, Westminster, 8 p.m. Discussion of Mr. B. J. Arnold's Address to the Joint Meeting at St. Louis "On the Problem of the Alternate Current Motor applied to Traction," and Mr. F. Creedy's paper, "The Alternate-Current Series Motor."

Journal of the Society of Arts.

No. 2,736. **VOL. LIII.**

FRIDAY, APRIL 28, 1905.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

NOTICES.

NEXT WEEK.

MONDAY, MAY 1, 8 p.m. (Cantor Lectures.) ALAN S. COLE, C.B., "Some Aspects of Ancient and Modern Embroidery." (Lecture I.)

TUESDAY, MAY 2, 4.30 p.m. (Applied Art Section.) J. STARKIE GARDNER, F.S.A., "The Monumental Treatment of Bronze."

WEDNESDAY, MAY 3, 8 p.m. (Ordinary Meeting.) MRS. BURTON-BROWN, "Recent Excavations in Rome."

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

Thursday afternoon, April 6th; THE MOST HON. THE MARQUIS OF BATH in the chair.

The CHAIRMAN was sure Sir George Scott required no introduction to the present audience; they were all well acquainted with his distinguished career, and no one was better qualified than he was to deal with the subject of his paper. Before calling upon the author to read his paper, he ventured to suggest that they could not pass over in silence the terrible calamity which had just overtaken India. It was, to his mind, an overwhelming disaster, and he felt that they ought to express their deep sympathy with those who had suffered in the terrible earthquake.

The paper read was—

THE PROSPECTS OF THE SHAN STATES.

BY SIR J. GEORGE SCOTT, K.C.I.E.

The Shan States form the most easterly part of Burma, which is the easternmost province of our Empire in India. Beyond the borders of our States lie the territories of China, French Indo-China, and the kingdom of Siam. There was a time when four empires met at Alanlegyet, the "Hill of the Four Standards," but we did not urge our claims to the limit. The Mèkhong river is the common meeting-space of the four countries, but they nowhere all touch at one point. On a map of Asia, however, the distance may be disregarded.

In most parts the populations beyond the frontier are also of the Shan and Tai race—Chinese Shans, French Shans, and Siamese Shans. It has, however, to be noted, that although the Shans are always looked upon as a hill race, they themselves consider that they are nothing of the sort, and, as a matter of fact, they are in the vast majority dalesmen, or dwellers in the wide straths, which many hundred years ago were lakes. Formidable hill ranges mark the frontier line in most places, and these are occupied by a great variety of hill tribes, many of them of an entirely different family from the Tai, such as the sanctimonious Rumai or Palaungs, or the head-hunting Wa, who belong to the Môn-Hkmêr subfamily; and the Lahu and Akha, who may or may not be Tibeto-Burmans, as is suggested, on the strength of a few vocabularies, by the learned editor of "The Linguistic Survey of India." Others who have studied the races in their hills are inclined to hint tentatively that at any rate the Akha may be Môn-Hkmêr, or may even represent the races of the Lemurian continent, now beneath the waves of the Indian Ocean. But beyond these ranges, the valley-dwellers north, east, and south are Tai. All the rivers, great and small, run southwards, separated by huge parallel ranges starting from the eastern Himalayas and all falling away to the south. One of them, the eastern watershed of the Salween river, far outrivals the others, and forms the backbone of the Malay Peninsula.

It is this breaking up of the country into long, narrow valleys or big oval straths, or here and there west of the Salween, and in the Lao States of Siam, into wide billowy, grassy

downs, this subdividing and separating and isolating, which have most affected the Tai character. The Tai extend from Assam to within hail of Canton; they are found from the waters of the Gulf of Siam to far up into the province of Yünnan. They are, beyond all question, the most important race in Farther India or Indo-China, and yet for several centuries they have occupied no more worthy position than that of intruders, as when they supplied kings to Burma; or of confirmed and aimless fighters, as when they quarrelled among themselves and overthrew their own most prominent State with monotonous regularity. The farthest wanderers have become the most settled, but it is apparently only because they forgot that they were Tai. The Ahoms conquered Assam, and even gave it its name, but they, themselves, have been as completely absorbed and assimilated as the Normans were by the Saxons in England. The Siamese were nearly as greatly influenced by the Hkmêr of Chiampa. They took their literature and written character, and many customs from them, including the boot-brush-like, shorn and cropped tuft of hair now worn only by the old-fashioned Cambodian or Siamese, and though their language still retains the most palpable relationship with the Tai speech of the north, they themselves have only realised within quite recent times that they are merely far-wandered Shans.

It is partly the character of the country which they live in, and partly a sensitiveness or susceptibility of disposition, which led them to assimilate with the peoples with whom they came in contact, which has prevented the Tai from taking the place in history which their numbers and occasionally their enterprise warranted. The Ahoms, that is to say "the Peerless," adopted the language, the code of laws, the civilisation, the customs, and even the religion of the people whom they conquered. The second Tai chief became a convert to Brahmanism, and the people are now practically merged in the Hindu population. The Tai in Siam did practically the same; they derived their alphabet, code of laws, civilisation, and many customs from the people whose place they occupied, but since the Hkmêr were Buddhists, they did not change their religion.

Early History.

The Tai have no traditions whatever of prehistoric wanderings. It is possible that they come from Turkistan, but it is certain that they were in the south-western provinces of China when the Burmese migrated. There they occupied, at any rate, the whole of western Yünnan south of the Kinsha Kiang, and gradually extended their boundaries. This area was the kingdom of Nanchao referred to in Chinese annals which have been discovered and translated by Mr. E. H. Parker, late of the Chinese Consular Service. Unfortunately, the Chinese are just the opposite of the Tai. They habitually make their notions of foreign nations conform to their own national custom; consequently they torture the titles of the Shan kings so as to make them fit into the Chinese system of *hsing*, or family names. Thus the names of Si Nu-lo, who about 649 A.D. formed the first Nan-chao kingdom; of Koh Lo-Fêng, who built the city of Tali in 743; or of I Mou-sün, who marched an army far into Ssu-ch'uan, suggest neither modern Shan names nor titles. There can, however, be no doubt that they were Tai, and that in the eighth and ninth centuries they were a formidable military power, and came near to overthrowing the Chinese dynasty of T'ang. Tali was their capital. It was founded in 743 under the name of Yang-tsü-me, and did not get its present name of Tali until 764. The Nan-chao kingdom was a descendant or a continuation of the kingdom of the Ailao, a name still given to the Shans by the people of the north and west of Tongking, and indeed the name by which the inhabitants of the Siamese Shan States still call themselves and are called. The earliest Burmese history speaks of the Pyu, whom the Chinese also called Piao, as being one of the three earliest tribes, the Pyu, the Kanran, and the Sek, that inhabited Burma. They are said, or fabled, to have been welded into one political unit by Kshatriya princes who came over from India and formed the earliest kingdom of Burma. Now the Nan-chao kingdom, and the Ailao dominion before it, are said to have bordered with Magadha and to have had a preponderating influence, if no more, over the Pyu. It is possible, therefore, that these Pyu, of whom no trace can be found, were Tai, or, at any rate, were cognates of the Tai, and that the Shans, even thus early, in the thousand years between 500 B.C. and 500 A.D., when the tribal shiftings were kaleidoscopic and as transient as the floating of a cloud over a mountain peak, were intimately connected with and had a strong influence over Burma. It is possible, there-

fore, that the King Thamóddarit, who in the second century of our era founded a capital and a new dynasty at Pagan, on the Irrawaddy, may have been a Tai.

The first definite name that we have of a Shan king, however, is that of Si Nu-lo, who took to himself the title of "Marvellous Prince and Divine Founder," and built his capital 35 li—say 10 miles—north-west of Mêng-hwa Ting. This happened in 651 A.D., and the five other *chao*, who then ruled States in Yünnan, were all absorbed into the one dominion, with the name of the Great Mêng kingdom, or Southern Chao (Ta Mêng Kuo, or Nan-chao). It is stated that thirty-two princes, covering a period of seventeen generations, had preceded Si Nu-lo in his principality. Besides the six Chao, or princes, there are references to "the thirty-seven tribes," so that even in those days there was the tendency to minute subdivision. Although Si Nu-lo took to himself the title and powers of sole chief, he does not seem to have suppressed the other Chaos. That was left for his great-grandson, P'i Lo-koh, to do. That potentate, who was thirty-one when he succeeded to the throne, apparently found the Chao refractory. He invited them all to a grand feast and sacrifice in honour of their ancestors — a *hsing-hui-chieh*, "the feast of the returning star"—which had originally been instituted in memory of a virtuous Shan widow, who preferred to be burned to death rather than marry an amorous and pressing Chinaman. The feast was an annual function, held in the summer, and the Chaos and their relations had, therefore, no hesitation in coming. P'i Lo-koh had a raised stand built for their accommodation, and when the Chao were all lying drunk upon this, after the dinner, he went down and had the scaffolding surrounded by armed men, and set fire to it. One of the Chao had not come to the festival at all, but the others were burnt to death. P'i Lo-koh's treachery was characteristic of the times, and rather appealed to Chinese ideas, so the King of Nanchao was made Prince of Yünnan, and Duke of Yüeh, which suggests that he had influence in Annam. The battles which he fought, however, so far as is recorded, were against the Tibetans and Mi barbarians, who may have been tribesmen in the country of the Miaotzu.

It was Koh Lo-Fêng, P'i Lo-koh's son, however, who was the first really formidable King of Nanchao. He succeeded to the throne in 748 A.D., and was granted the title of Hereditary Prince of Yünnan, while his son Fêng Ka-i, who had gone to the Chinese Imperial Court, besides receiving a variety of dignities, was given an imperial princess in marriage, and also was presented with a band of Turkish musicians.

The misconduct of a Chinese prefect, however, roused Koh Lo-Fêng's indignation, and he declared war on China; defeated a large army sent against him, seized a number of Chinese towns, and transferred his allegiance or alliance from China to Tibet. In 752 the Tibetans sent him a number of presents and recognised him as a quasi-independent *giulbo*. Two years later Fêng Ka-i routed another Chinese army in the neigbourhood of Tali-Fu, and pursued them as far as western Ssu ch'uan. The Chinese are said to have lost 200,000 men in these campaigns, and Koh-lo-Fêng erected a mausoleum over the bodies of those who had perished at Hsia-Kuan, the commercial town of Tali-Fu.

I Mou-Sün succeeded his grandfather, Koh Lo-Fêng in 778, and, along with the Tibetans, made a raid far into modern Ssu-ch'uan, but was defeated and driven back. The defeat cannot, however, have been very serious, for the Chinese Emperor made conciliatory advances, which I Mou-Sün accepted, and broke with the Tibetans. In 794 he defeated a Tibetan army at the Iron Bridge over the Yangtzu, north-west of Likiang-fu, and was rewarded by the Emperor with a gold seal and the title of King. The Nan-chao State is said to have been bounded in his reign by Chinese Yünnan, Kiao-chi (Tongking), P'iao (Burma), and Tibet.

The next Nan-chao ruler of note was Fêng-yu, who marched as far as Ch'êng-tu, the capital of modern Ssu-ch'uan, and carried off immense booty in the shape of valuables, books, and prisoners. He had to restore 5,000 of his prisoners, but he compensated himself by carrying off 3,000 P'iao, or Burmans, with whom he founded a new city, and in 840 he conquered Annam, at that time desperately misgoverned by the Chinese. It is probably from his temporary holding of the country that the Muong settlements in Tongking date. These Muong are indisputably of the Tai race, as are also the Do of the Caobang neighbourhood.

It was probably on account of this invasion that there was war again between China and Nan-chao, but in 859 the Chinese were disastrously defeated at a point a little north of the Iron Bridge near Likiang-fu. Fighting

with the Chinese went on for several reigns later, but the old Tai dynasty was put an end to, by massacre, in the beginning of the tenth century. As many as 800 persons are said to have been put to death, the whole of the Mêng family and their relations. The dynasty had lasted 255 years from the time when Si Nu-lo established himself, and during this period there had been thirteen kings of Nan-chao. For three and a-half centuries after this Nan-chao was governed by a family of Chinese Shans with the name of Twan. They were more Chinese than Shan, and it seems certain that during all this time the original Tai kingdom was being gradually absorbed by settlements of Chinese in the country. It is, at any rate, certain that parties of Tai from Nan-chao moved southwards and established various principalities in the Lao country, Luang Prabang, and Wying Chan on the Mèkhong, Chieng mai on the Mènam, and others of the many States now existing in Upper Siam. Whether these parties moved of their own accord, or because space was becoming limited on account of the settlement of Chinese colonies, there is nothing to show, but, at any rate, it is very clear that the Tai had spread far beyond their original limits long before Kublai Khan put a final end to the parent kingdom in the end of the thirteenth century.

In the Nan-chao chronicle it is frequently recorded that the rulers received Chinese envoys and generals with Turkish dances and songs, and it is specially noted that in the wars with Tibet, I Mou-sün took prisoners a number of Abasside Arabs and Turkomans of Samarcand. A celebrated Korean in Chinese employ also at this period crossed the Pamirs, and for the first time carried Chinese arms into Chitral, Baltistan, and the whole of that neighbourhood. Through this there came about active political relations between the Caliphs and the Chinese emperors.

It is, at any rate, probable that the Chinese Mohammedans resident in Yünnan, whom we call Panthays from the name given them by the Burmese, are the descendants of these prisoners taken in the Tibet wars by I Mou-sün and other Nan-chao rulers.

The Chinese chronicle is very curt, very matter-of-fact, and not a little disdainful and ignorant, but from allusions every now and again it seems certain that it was only when there was a particularly energetic man among the Chao that there was one acknowledged head and supreme ruler. At other times the dominion was a confederacy rather than a kingdom, and the formidable power gained during the time of one man of capacity was frittered away when his energy disappeared. If it had not been for this source of weakness it seems well possible that the Tai might have overthrown the Chinese empire, which was struggling to form itself out of a chaos of contending States, and might have established themselves as the rulers of China. But the tendency of the Tai has always been to fritter away their strength. Even at the time of their greatest power constant swarms seem to have left to form new principalities to the south in the valleys between the Salween and the Mèkhong rivers. None of these seem to have rendered any allegiance to the parent kingdom of Nanchao, so far as can be ascertained from the meagre histories and traditions.

Dispersal.

This tendency which all Tai history shows to have been regular and never-ceasing was of course greatly strengthened by the final overthrow of Nan-chao by Kublai Khan. Even if there had been no tendency to migrate before this it would have been suggested now, and the bulk of the people would have left the country where their rulers had disappeared and their national form of government had ceased to exist.

But it seems certain that the general movement west and south of the Tai tribes, which followed the establishment of Uriangkadai in Tali-fu was the mere accentuation of a habit which had long existed, and was not prompted by the conversion of their king into a Mo-ho-lo-tso (or maharajah) and the introduction of Mongol rule. They now proceeded to occupy a great part of Upper Burma, furnished that country with kings, and had a predominant influence for a period of about 250 years. They pressed down to the Gulf of Siam, where they founded the city of Ayulthia, on the site of the ancient Khmêr, capital town of Lawek or Love, and thus completed the separation of the members of the Môn-Annam family, the Peguans on one side and the Cambodians on the other. Since then they have never occupied a prominent position. It is true that Siam is the last of the independent Indo-Chinese kingdoms, but it is, as a kingdom, overlaid with Khmêr culture, hardly admitting itself to be Tai at all, and looking upon the tributary Tai chieftains as people of a distinct race. Although they were much more nearly connected with Chinese civilisation

and ways than with Indian, yet, beyond their chronology, the Tai have taken very little from the Chinese. The Nan-chao State had a tradition that they got a ruling family from Magadha. Whether that be true or not they certainly got their Buddhism from there. King Asoka, of Magadha, the grandson of Chandragupta, the Sandracottus of the Greeks, was a great missionary king, and it was no doubt he who introduced Buddhism into the Tai country and into Tibet, somewhere about 300 B.C. There are pagodas pointed out in the Shan States now, which are said to be of the nine hundred thousand nine hundred and ninety-nine, founded by order of King Asoka.

The architectural style of their pagodas, the language of their religious works, and the type of their Buddhism, is all Indian. The British Shans, undoubtedly, took their written character from the Burmese. The Lao Shans and the Siamese took theirs from the Hkmêr of Chiampa. Yet their language has undisputed affinities with Chinese, and none whatever with the Tibeto-Burman.

The Shans present the somewhat curious spectacle of a race exceedingly ready to adopt the habits and ways and refinements of the peoples with whom they came in contact, either as neighbours or as conquerors, and yet exceedingly tenacious of the national characteristic of a liking for small communities, in confederation with others of their race, but steadily averse to subordination to one central power, which would have given them the stability and the conquering force which might have made them masters of all Indo-China, to say nothing of possibly some of the provinces of China itself. The Burmese have been given the reputation of having devised the sagacious policy of splitting up the Shan States and so ruling them with ease, but the truth is that they would have had much more difficulty in persuading the people to submit to the rule of one or two chiefs of greatly extended territories. Similarly the policy of the British Government was to recognise all States found in existence at the time of the occupation of the country, and to confirm in the control of them the chiefs found in possession. As a result there are many chiefs whose States are much too small to offer any hope of even becoming wealthy or important, and not a few of them are so small as not to be able to afford the expenditure necessary on main-trunk roads, which pass through their territories. Yet in the few cases where chance has offered a favourable opportunity for the joining together of neighbouring small States, it is the inhabitants of these States who have been most hostile to the project.

Kingdom of Pong and Ko-shan-pyi.

For years no allusion to the Shans was complete without a reference to "the Kingdom of Pông," and to the Ko-shan-pyi, "the nine Shan States." In 1835, Captain Pemberton found a Shan manuscript in Manipur. This was translated and immediately afterwards lost. This chronicle makes frequent reference to "the Kingdom of Pông." The same kingdom is mentioned in the list of his conquests by Anawrat'a, the great King of Pagan. The name is altogether unknown to the Shans, and appears in no chronicle that has so far been recovered. Nevertheless, much ingenuity has been wasted in attempting to identify it. Sir Arthur Phayre said it was Mogaung, now a subdivision of the Myitkyina district. The late Mr. Ney Elias was convinced that it was Mông Mao, a small Chinese Shan State, a few miles away from our frontier market village of Namhkam. Mr. E. H. Parker, by dint of Chinese learning, proves it to be Luh-ch'wan, a place which no longer exists, and which, while it did exist, had very indeterminate boundaries, and was known to a very limited number of Chinamen and to no Shans at all.

The one outstanding fact about Burmese and Shan early history is that there was a perpetual succession of principalities which obtained an alternate preponderance, due to the energy of the ruler for the time being. Nothing but a kaleidoscope had the same number and variety of combinations. But every local historian, from a desire to prove a respectable antiquity for the subject of his chronicle, claimed that the various other principalities were merely different seats of power which ruled over his particular State. The confusion which results can only be compared to views from two or more bioscopes thrown on the same screen and revolving in opposite directions.

It is possible that there was a kingdom of Pông with a separate existence, but the probability seems to be that the reference is to the Nan-chao kingdom. King Anawrat'a is said to have visited, and probably believed that he did visit, China. But he really got no farther than the capital of Nan-chao, Tali-fu, and instead of getting the Buddha's tooth, which he was in quest of, he only got an image which had touched it. On his return, the courtly

chronicle said he had conquered the kingdom of Pông, which really meant that he had visited Nan-chao. Incidentally it is recorded that on the way back he married the daughter of the chief of Möng Mao. Therefore, Möng Mao got entangled with the phantom kingdom of Pông. The incident derived an additional notoriety from the marriage. The king had other wives who were very jealous of the Shan Princess. There were many plots, and she had to go through a great number of trials, but was finally triumphant over her rivals. All this is recounted in a drama, which is one of the most popular on the Burmese stage, and has helped to fix attention on the kingdom of Pông. All that can be said is, that Pông seems to be Nanchao, and that it is possible that Möng Mao was one of the feudatory princes of the southern confederacy.

The name Ko-shan-pyi seems to be more easily explained. Kawsampi is the common classical or Buddhistical name for the Shan country. It is continually used even to the present day. The name was, no doubt, borrowed from Kosâmbi in the Dúab, a famous Buddhist kingdom in Gangetic India. The Burman historian could not bring himself to admit that a Shan principality had a right to a classical title, if indeed he knew that Kawsampi was classical. He, therefore, transformed Kawsampi into Ko-shan-pyi, the nine Shan kingdoms, and then proceeded to speculate as to which these nine kingdoms were. There are lists of the nine principalities given to the present day, but it is never possible to prove that there were not other principalities existing at the same time. In fact, it seems as doubtful that there were, as it is certain that the seven kingdoms of the Saxon Heptarchy never flourished at the same time.

The name and the implied fact of the Ko-shan-pyi was, however, introduced to English readers by Buchanan-Hamilton in the *Edinburgh Philosophical Journal*, and, as a result, Ritter, Burney, Hannay, and many others have given conflicting lists which strove to fix these nine Shan States. Any Shan chief or minister of State will give you a list now, but it is extremely improbable that the lists will agree. It is only one more of the mass of popular errors.

The Various States.

The British Shan States have an area of 59,915 square miles, and are, therefore, a little larger than England and Wales with the Channel Islands and the Isle of Man. They are divided for purposes of administration into two charges, the Northern and the Southern. In the Northern Shan States there are five chiefs, all Sawbwas, and a sixth territory beyond the Salween river which contains the settlements of the Wa, or conglomeration of village communities some federated some independent. In the near future it seems probable that the State of Möng Mit will be added to the Northern Shan States. At the time of the occupation the chief was an infant in arms. He was educated in British schools and his State was administered as a sub-division of the Ruby Mines District. The young chief is now a Cadet and a fair rifle shot, and he has qualified himself for administering justice in his State by holding and exercising second and third class magistrates' powers in various parts of Burma. In a short time now he will be of age and put in charge of his State, and this will no doubt be then added to those under the charge of the Superintendent of the Northern States.

In the Southern Shan States there are forty-three States, five of which, however, are Red Karen, whose independence was guaranteed by us to them in a treaty with King Mindôn of Burma in 1875. The chiefs are, therefore, not on quite the same footing as the Shans. They do not pay tribute and their territories are outside of British India.

Beside the two main groups of the Shan States, there are a few others isolated in Burma proper, which have survived from the time when the Tai empire spread itself all over Northern Burma. Two of these Sinkaling Hkamti and Hsawnghsup, on the Chindwin river, towards Manipur, are quite insignificant, both in size and population. Another is considerably more extensive, populous, and well-to-do, the State of Hkamti Lông. It lies in the Valley of the Mali, the western branch of the Irrawaddy river, surrounded on all sides by the Chingpaw tribesmen, to whom the chief has long paid blackmail to secure protection and immunity from attack.

These States vary enormously in size. Këngtung, with its dependencies, has an estimated area of 12,000 square miles, that is to say, it is about the same size as Belgium, or say the four English counties of Yorkshire, Lancashire, Lincoln and Hertfordshire. North Hsenwi has an area of 6,330 square miles, or only about 1,000 square miles less than Wales. South Hsenwi covers 5,000 square mile, and Hsipaw, with its dependent States, 4,524.

The State of Manglön, with the various Wa States, extend to about 5,000 square miles. Of the others, one is over 4,000 square miles, one is 3,500 square miles; five are over 2,000 square miles, that is to say, they are considerably larger than many of the States of the German Empire. Some, however, are quite insignificant in size; for example, Nam Tôk is no more than twenty square miles, and Kyông is only four square miles larger. There are three States with over 1,500 square miles and one with only seven square miles less. Four States range between 500 and 1,000 square miles. Fifteen have more than 100 square miles and less than 500. Three range between 50 and 100 square miles, and ten have less area than 50 square miles.

In the fifteen States of the Myelat, the intermediate country between Burma and the Shan States proper, there are practically no Shans. The inhabitants are Danus and Danaws and Dayès, and Taungthus and Taungyos, with a number of Karen tribes in the country to the south. Similarly in the Karen-ni States there are only a few Shan settlements here and there, and the State of Hsatung is very largely Pa-o, or Taungthu, including its chief. Similarly in the Northern Shan States the population of Taungpeng-loi-lông is Rumai or Palaung, Manglün is Wa, and considerably more than half the population of North Hsen-wi is non-Shan, a mixture of Chingpaw or Kachins, Palaungs and Chinese. The Shans of Kēng-tung pointedly call those of their race west of the Salween Tai, and reserve the name of Hkün for themselves. Still the Hkün are practically confined to the country round the capital and the Lü, who inhabit, Keng Hung State, also form a large proportion of the Shan population of Keng Hung. They are much more closely allied to the Lao or Siamese than to the British Shans, and their written character was undoubtedly derived from the Cambodians of the old Hkmêr kingdom.

The stretch of country where the Tai are found most continuously and in the greatest proportion, is in that portion which may most reasonably be called the plateau, the broad billowy plain which extends from Mawkmai due north through Möng Nai, Lai-hka, and Möng Nawng, to South Hsenwi. Yet even here there are wide districts where the Riang tribes greatly outnumber the Tai. And everywhere on the ranges which separate the States from one another, there are hill tribes absolutely distinct from the Tai, though subject to and paying tribute to them.

They, therefore, still retain the characteristics of splitting up and isolating themselves which have marked them throughout their history, and have prevented them from attaining to the power which their numbers and their energies would have entitled them to grasp.

The Burmese are usually credited with the policy of dividing them and preventing quarrels between the States, so as to make it the easier for them to govern the Shans and prevent united risings; but it hardly seems that it was a calculated policy. It was the natural bent of the Shan character, no doubt, fostered and exaggerated by the features of the country.

Civil War and Ruin.

For the twenty or thirty years before the occupation of the country by us, however, the States had been in a perpetual ferment of civil war. This began with the southward pressing of the Chingpaw tribes. They steadily overran the great northern State of Hsenwi and occupied quite half its area. The Burmese ascribed this to weakness on the part of the Sawbwa. They put that potentate in gaol and appointed another, and then another, with no satisfactory result. They then varied the process by appointing a series of Burmese civil and military officials with even less advantage, either to their own grasp of the country, or the settlement of affairs. They released some of the Tai chiefs from gaol and re-appointed them one after the other. They also called upon the Southern chiefs to send contingents to fight the Kachins, but the result was never final and seldom even satisfactory, and the State of Hsenwi, which used to be as large and powerful as all the other Cis-Salween States together, was broken up and ravaged and depopulated long before we had anything to do with the country.

Then King Thibaw oppressed and plundered Möng Nai the great Southern Sawbwa, until he rose in revolt and massacred the Burmese garrison at Monè, the largest town in the Shan States, and the residence of the Burmese Governor of the Principalities. The other Sawbwas were then called upon to aid in the punishment of Möng Nai, and he and certain other chiefs, connected with him by marriage and other ties, were driven beyond the Salween and took refuge in Kēng-tung, where the Burmese garrison had been massacred some time before.

British Occupation.

When King Thibaw was dethroned, it was practically a twelvemonth before we took over the Shan States, and in that period the Mōng Nai, Sawbwa, and other exiled chiefs came back to their States and proceeded to wipe off all old scores, and to replenish themselves with their own or other people's plough-cattle out of the States which had joined with the Burmese in expelling them. When, therefore, we took over the Shan States, it was practically in a state of universal ruin. Monè, which within living memory had had ten thousand households, was reduced to seventeen huts, and the town of Laihka was even more thoroughly destroyed.

We met with practically no opposition whatever, and peace was restored by the simple process of marching to the capitals of States, but the rehabilitation of the country has been a much slower matter. For a year or two there was not a little distress, owing to the thoroughness with which the marauding bands had destroyed all seed grain and driven off or destroyed plough-cattle. The fertility of the hill valleys, with their soil yearly renewed by silt washed down from the hills, soon put an end to this, and it was thought that the States would soon recover a certain amount of their former prosperity and attain to even greater wealth.

Trade.

In the old days huge caravans of pack bullocks had travelled about the country carrying manufactured goods and hardware, salt and fish paste, kerosene and candles, and had bought quantities of local produce as they moved about. In Burmese times the roads were far from safe, and there were constant tolls which put heavy restrictions on trade. But the joining together of a number of caravans gave safety against dacoits, and the tolls were not able to kill the trade, perhaps because they were mostly levelled in kind. In those days the Myelat, the half-way country between Burma and the Shan States, did a huge carrying trade. The merchants from below came up to various centres in the Myelat and sold their goods there, and these were then carried by the Myelat bullock caravans to all parts of the Shan States. For a time this was carried on after we took charge of the country, but it has been gradually dwindling away. In place of the thousands of pack bullocks, there are now only hundreds, and the wealthy middlemen of the Myelat have now sunk into a hand-to-mouth existence and often have gone back to the cultivation of the soil.

Part of this is due to the construction of the railway to Mandalay, which has brought goods much nearer to the hills, but a much more serious enemy to the pack bullock men has been the Government cart-road. The carts can go all the year round, whereas the bullock caravans could only travel in the rains when water and fodder were plentiful. Moreover, the carts can carry much more than the bullocks could, and they can travel in twos and threes or even singly. They can also carry goods which could only with great difficulty be loaded on pack bullocks.

It may be thought that all the pack bullock owners had to do was to furnish themselves with carts and carry on their old trade, but the matter is not so simple as that. The training of the pack-bullock to pull at the yoke was not an easy matter. Cattle accustomed to stroll along at their ease under the shade of trees, through bushes and along the cooling beds of streams did not accommodate themselves to the dusty and monotonous ways of the cart road, and where they were accustomed to choose their own paths across a swampy piece of ground they resented the hard and fast narrow limits of a Serbonian bog on the Government road which could not be skirted and was filled with other carts in as unpleasant a plight as themselves. Consequently the pack-bullock owners did not become the possessors of carts. There were soon a number of carts plying, but these were the property, not of the inhabitants of the Shan States, but of Burmans and natives of India, living down in the plains. In the great majority of cases, moreover, these men were not traders, but mere carriers, and with no desire, except to get as much as they possibly could for the carriage of goods. The prices of merchandise were soon very much reduced in the Shan States, but the money for the carriage of them all went out of the country, instead of going into the coffers of native carriers, who would have spent it again in the Shan States. The people paid much less for their luxuries. They had a greater degree of comfort, but they had much less money to spend than they used to have. More over, a great deal of their export trade has been lost. Before the construction of the railway from Toungoo to Mandalay, there was a considerable market for various kinds of produce in the plains. Quantities of dried chillies, onions, cardamoms, and turmeric

were, till quite recent years, sold in the plains. But more and more of these crops have been grown along the railway line, and no doubt more and more are brought from other places. At any rate, the export of the goods has shrunk, until now there is hardly any export whatever, and the cultivators have to reduce their plantings since the local sale practically does not increase at all.

All this, however, would be a matter of indifference if the Shan States were able to take advantage of the crops of which they have nearly a monopoly, crops moreover which have been introduced since the British occupation. It has been proved that the wheat grown in the Shan States is of the most excellent quality, and also that the area where it can be grown is capable of nearly indefinite expansion. By sowing at different altitudes, on different soils, and under varying conditions, wheat could be reaped over two-thirds or three-quarters of the year. Unfortunately, however, the cost of cart hire makes the cultivation impossible. Before the wheat can be got to the railway, the expense of carriage is so great that it cannot be sold except at a loss. Consequently wheat brought at great cost from India for the flour required by the Sepoys of the native regiments is in use in all the military stations in Burma, and the Shan States wheat, which is of admittedly better quality, can only be utilised for the local needs, which hitherto have been very small. A similar state of things prevails in the growing of potato crops. The potatoes grown in the Shan States are of the most excellent size and quality, but potatoes brought from Marseilles can be sold cheaper in Rangoon than potatoes from the Shan States; last season potatoes were selling on the fields in the Myelat for one rupee the hundred viss, that is to say eighteenpence for 370 pounds. But the cost of carriage was nine times that amount, so that when the potatoes got to the railway no profit, or only the most insignificant profits were to be made. Similarly the European fruits and vegetables, which grow in great quantities and of very creditable quality, cannot be exported, partly because cart carriage is much too slow for them, and also because the cost of export is so great that the selling price would be prohibitive.

NECESSITY FOR A RAILWAY.

So far, therefore, the British occupation of the Shan States has been of very doubtful advantage to the traders of the country. They enjoy the blessings of peace; the country is much more accessible than it was, and the chiefs have improved the lines of communication in all directions, but so far from more money coming into the country it seems rather that more is going out, and so far from the prospects for the future being brighter, it seems that they are becoming steadily more discouraging. For some years now the volume of trade has been slowly but gradually decreasing, and last year a considerable falling off in the trade returns was only prevented by an unexpected demand for stick-lac and for horned cattle, neither of which is likely to be maintained.

It might, therefore, be said that improved communications have been a disadvantage to the Shan States, and that, since a cart-road has been of no great help, a railway is not much likely to be more valuable. This, indeed, actually has been said, and the Mandalay-Lashio Railway has been pointed out as a proof not only that a railway to the Shan States will not pay, but that it will not do any appreciable amount of good to the States themselves.

But the Mandalay-Lashio Railway cannot be looked upon as a railway opening up the Shan States at all. It is the beginning of a railway intended to reach Yünnan or to penetrate into the province of Yünnan and beyond. As far as the Shan States are concerned, it merely skirts them as a cat walks round the walls of a room instead of going straight across it. The whole of the country to the north of the railway is a jumble of hills inhabited by Kachins and Palaungs, races who do not trade and never have traded, and do not seem likely ever to become good traders. The Palaungs it is true grow and export tea; they send out a certain amount in the form of dry tea and a still greater amount in the form of salad tea, or pickled tea, a compound which is neither a *hors d'œuvre* nor a *zakouska*, nor a kind of *pan sopari*, and yet has a little of the characteristics of all three. The amount of tea likely to be produced does not seem likely ever greatly to exceed what is produced now, and this amount is very far from employing a large number of goods wagons. There is no other export trade to speak of except what is beginning slowly to grow up from the States to the south-east, and no doubt in time will help to make the railway self-supporting.

The railway follows the line of a geological fault which runs east and west, a subsidence or uprising of the ground which marks the northern end of the M. Nai Laihka plateau,

and is traced across the map by the line of the Nam Tu, a river known as the Myit Ngè, where it enters the Irrawaddy, between Ava and Amarapura. Everywhere else the ranges run north and south. Here the abrupt lines of precipitous cliffs go, as nearly as possible, east and west. It is, therefore, an obvious invitation to a railway which wants to make its way eastwards. But the fault does not extend all the way westwards to Burma. On the contrary, it comes to an end not very far to the south-west of the capital of the Hsipaw State. Though, therefore, this east-west valley is a distinct temptation for a railway, it is a temptation for a railway which is to go on to the Kunlông ferry; to go up the Nam Ting valley; to go into Yünnan; to go to Chung King, and, eventually, no doubt down the Yangtzu to Shanghai, or perhaps across Kuei-chou and Kwang-si to Canton and Kowlun, opposite Hong Kong. It is not the line for a railway which is to be of any special use to the Shan States.

Moreover, in the preliminary approach to this piece of good fortune, it was entirely unnecessary to make for it straight from Mandalay. The ascent to the plateau straight east from Mandalay is at about as difficult a point as is to be found on the whole face of the wall of hills which the Shan tableland presents to the Burma plain. If it is not the most difficult it is, at any rate, far more difficult than very many other lines of approach, and, moreover, it implies the necessity of crossing the abrupt gash which is known as the Gôkteik (or Hokiit) gorge, and is spanned by what was the highest bridge in the world till the completion recently of the Victoria Falls Bridge in South Africa. The Mandalay-Lashio Railway is, therefore, a desperate mistake. It has been ruinously expensive, because it took an altogether unnecessarily difficult route to begin with. It goes through a country which was nearly entirely depopulated in the disturbances which preceded our occupation of the Shan States. It does not serve the Shan States because it creeps along the extreme verge of them, or, at any rate, the extreme limit of the country which is capable of producing valuable exports. It stops short at a point which has nothing to recommend it except that it is the headquarters of the Superintendent of the Northern Shan States. It is a railway which should never have been begun, if it were not intended to carry it on at least to the China frontier, if not into China. Yet it is quoted against the construction of a railway which will open up the Shan States, as a proof that no such railway can be made to pay. The line of approach was adopted because of the attractions of Maymyo, a pseudo-hill station, which merely furnishes a change of temperature and not a change of climate, and possibly also by the attractions which the construction of a formidable bridge had to the professional mind. If, instead, the ascent to the hills had been made from Thazi Junction on the Mandalay Railway, in the Meiktila neighbourhood, the ascent would have been easier; there would have been no big bridge, and the approach to the Kunlông ferry, and Yünnan could have been none the less easily attained in the Hsipaw-Lashio neighbourhood; while the southern Shan States would have had an opening made for them to the railway.

The Southern Shan States Railway Survey.

A survey has been made of this approach to the Southern Shan States from the Rangoon-Mandalay Railway, at a point near Thazi Junction to the neighbourhood of Taunggyi, the headquarters of the Southern Shan States. The length works out to be a little under a hundred miles, and the cost would be about Rs. 67,000 the mile. The survey shows no gradient heavier than one in forty, which compares very favourably with the many gradients of one in twenty-five on the Mandalay-Lashio line. On the other hand, the survey was made for a two-feet four inch gauge, which makes it much easier to take sharp curves than is possible with the three-foot gauge, which is that of all the Burma railways. No doubt the difference in mileage cost between a two-foot and a metre gauge would be considerable, but it seems certain that a good deal of the value of the railway would be taken away if all goods had to break bulk on reaching the trunk line from the Shan States. It would certainly be a great disadvantage in the carriage of live stock, which is likely to be considerable, and still more so in the conveyance of perishable goods, such as vegetables and fruit, which seem likely to be exported in considerable quantities.

Sanction for the construction of this railway is withheld for the present by the Government of India, for the reason that the trade returns do not prove that there would be an amount of freight which would pay for the capital invested, and also for the alleged greater necessity for railways in the delta. The real

reason for these delta railways is that it is supposed they will be much more paying adventures. The Thonzè Henzada-Bassein Railway is practically finished. The Shwegyin Maulmein or Martaban line is to be commenced immediately. The trade returns from this quarter show that there will be an immediate return, but it seems a doubtful policy to duplicate means of carriage in one place, while there are practically none whatever in another. The delta is and always has been well served with a net-work of rivers and creeks, and the railways now constructed and to be constructed can only be rivals to the boats of the Irrawaddy Flotilla Company, and to the coasting steamers of the British India Steam Navigation Company. On the other hand, the Shan States have no outlets for their trade, or only outlets which impose a prohibitive cost.

Registration of Trade.

The Department of Land Records and Agriculture has kept, for some years, stations which are supposed to note the trade coming down from and going to the Shan States. Unfortunately the villages at the foot of the hills where these registration clerks should be posted are extremely feverish for the greater part of the year for all but inhabitants who have been born and brought up there. To avoid losing clerks through fever, or to escape having to pay exceptional wages, the registration stations have all been placed at some distance away from the foot of the hills, and as near as possible to the railway. This is, no doubt, convenient from the office point of view, and might also be satisfactory if all the trade made for the railway. This is, however, very far from being the case. When the carts and the bullock caravans reach the plains they can practically go across country in any direction they please, and they do. The number of carts and bullocks which follow the Government road and come to the Trade Registration Office is not great. It is impossible to say what proportion it bears to the total, but it seems not impossible that it is no more than from two-thirds to a half. Moreover, the registration clerk naturally only remains on duty during the day. During the night the office is closed, and it is precisely at night, at any rate in the dry season, that the great bulk of the traffic passes. The cartmen and the pack-bullock owners prefer to travel between sunset and sunrise, when both they and their animals escape the heat of the sun, and, as a consequence, all this traffic escapes registration. It is not surprising, therefore, that an estimate, from the published records of the traffic, seems to prove that the volume of trade is not sufficient to warrant the construction of a railway. But the records only show a portion of the trade which really does exist; and the confident anticipation of everyone who knows anything about the Shan States is that it is not the expansion of the trade now being carried on that will pay, but the entirely new trade which will spring into existence, whenever there is a means of carrying out the produce.

It may be said that wheat ought to have been grown along the line of the Mandalay-Lashio Railway since it would be so profitable a crop, and it certainly is curious that it should not have been grown. The explanation probably is that there are no cultivators there with the necessary experience. It was only after several years of experiment in a number of different places, and particularly at different seasons of the year, that wheat was grown with any success in the Southern Shan States. Experiment proved that different altitudes required different seasons for planting and reaping. This has to be learnt on the Northern Shan States line, and it would appear that no one there has the energy, or the capital, or the time, or the land to make the necessary experiments. It is also a singular fact that potatoes, which grow so freely in the south, do not appear to do well in the Northern Shan States. However that may be, the fact remains, that in the Southern Shan States the production of both wheat and potatoes will be limited only by the demand, and when they can be exported for a reasonable sum in the way of freight, the demand will be a constantly increasing one. At present all the wheat, or practically all the wheat, consumed in Burma is brought from India at a cost with which wheat grown in the province must naturally compete successfully. At the same time no figures can be shown, for the simple reason that, until there is a market, the wheat cannot be grown. All that can be said is that, any demand, however great, can be met.

Products.

Experiments have also shown that barley and oats can be grown, and if this is the case and oats can be freely produced, there will be an immediate market beyond the province, for the oats grown in India do not run to ear, and are useful as fodder rather than as pro-

ducing grain. It is also obvious that, until there is rapid carriage, the English fruits and vegetables which grow freely wherever they are planted, cannot find a market in the plains. Strawberries can be had for nine months in the year; in fact, the fruit only ceases to form during the period of the heavy rains. Very creditable peaches and apples, and figs are to be had, and the quality of these will, no doubt, steadily improve when it is profitable to attend to the cultivation. Numbers of the chiefs in all parts have planted orchards and vegetable gardens, but at present they are an interest rather than a speculation.

Oranges have always done well in certain parts of the Shan States, and considerable quantities are sold in Burma even now, notwithstanding the heavy rate of carriage, simply because there is no competition, and the price cannot be lowered to the disadvantage of the owners of the Shan orange groves. But with a reduction in the price there would no doubt be a huge increase in the amount sold. Cotton also grows very well in all the drier parts of the States. Great quantities are exported to Yünnan; in fact, almost all the mule caravans returning to China load up with cotton. The staple of the plant now grown is very short, but this seems a drawback which can easily be got over, and the addition of a new producing field may tend to steady the market and prevent the fluctuations which have been so disastrous to the cotton trade of late years. Coffee has been grown with great success by several chiefs, not with any view to sales, but merely as an interest to themselves. There seems no reason to doubt that plantations could be put down and extended to whatever size might be required. The cultivation of tea also seems simply to require the arrival of the planters. Wild tea plants are found in very many places, and all that is wanted is the knowledge necessary to produce a leaf fit for the European market or palate. It is undoubtedly the same with tobacco. At present large quantities are grown in the misty plains of Langkö and Nawng Wôp and elsewhere, but there is no attempt to cure the leaf. It is simply sun-dried, chopped up, and in this way is sold to local smokers. The settlement of planters of experience might not impossibly result in the production of a leaf as valuable as that of Sumatra, which is almost entirely sold for wrappers. Hemp, cinnamon, indigo, and a variety of rubber-producing creepers are also found freely; in fact, there seems very little that might not be grown, if only there were a means of getting the produce to the market in a reasonable time and for a reasonable price. The climate is one which would attract many British settlers if the States were made reasonably accessible.

Minerals.

Very little has been done so far in examining the mineral possibilities of the Shan States. Coal has been found in a great many places. It appears to be lignite in the majority of the fields, but it can hardly be said that the promise of the seams has been properly tested. A few examinations have been made by experts here, and there in places at no great distance from the railway, but they have not been by any means exhaustive, or indeed much more thorough than can be effected by an officer travelling about in a tent with any sort of digging implements that can be got locally and used by people who have never done any pit sinking in their lives. The coal inspected has almost invariably been taken from close to the surface, and is weather or water-worn, frequently both, so that the test cannot be said either to have been a fair or a final one. The best coal-tracts will, no doubt, be found in the limestone hills which run through the centre of the States; but when wheat and potatoes cannot be carried out of the country at a profit, the prospects of coal are very small. The coal found appears to belong to two distinct ages—the upper carboniferous and the tertiary systems. The former is probably not very valuable, but the tertiary coal might be of very good quality.

Iron ore is found in a great many places, and is worked locally in different parts of the States and converted by the neighbouring blacksmiths into *das*, swords, daggers and choppers, and a variety of agricultural tools and household implements. It is characteristic of the Shan States and perhaps of the East generally that the miners never act as blacksmiths. The blacksmiths, in fact, in almost every case, live in their own villages at a considerable distance from the pits where the ore is obtained. The principal iron-working neighbourhoods are Hkesi Mansam, where swords and daggers are chiefly made, and Laihka, where the things made are more for agricultural or domestic use. In the neighbourhood of the Yawnghwe Lake there was formerly a considerable iron manufacture; in fact the State of Pôn-mu, which no longer has a separate existence, in Burmese

times paid its tribute in the form of sword blades.

Grains of gold are found in practically every stream in the country. The sands of the Salween are full of it, and every year in the intervals of agricultural work, parties of Shans encamp on the river and gather enough gold dust to have a festival in their village when they go home again. Many of them do the same thing in local streams, panning out the gold in the crudest possible way in shallow round wooden trays. There is, in fact, no doubt whatever of the presence of gold over very wide areas, and gold-bearing quartz even has been found in several places. The Burmese had a conviction of the existence of gold in great quantities in the form of nuggets in the Shwe-Thamin-Chaung, the Stream of the Golden Deer, in the Wa States, and sent up a large army to occupy the tract. This force had great trouble with the Wa, and was eventually practically annihilated, without even reaching the Golden Stream. A British party, which visited the actual spot in 1897, found nothing tangible, but it was only there for an hour or two, and had no experts with it. At present gold could only be obtained by the expenditure of considerable capital, but it seems not impossible that gold pockets, or deposits of nuggets, may be found. A Burmese clerk, in the course of an afternoon's washing and digging in the banks of a small stream, got nearly an ounce of gold. When this has been done once it may be done by many, and possibly in many places. But the exploiting of the mineral resources of the Shan States must wait for the railway, no less than the cultivation of the soil, and agriculture will probably prove a more valuable, and certainly a more permanent asset than gold-mining.

Extension of Lashio Line into China.

While we have done nothing practical to connect the Shan States with the Rangoon-Mandalay trunk line, we have also done little to give outlets to its trade in other directions. The Mandalay-Lashio Railway is a mere example of faint-heartedness, and the projected railway from Bhamo to T'êngyüeh is only a further proof of the same want of determination. Every year there are hundreds of caravans which come westwards and south-westwards from Yünnan. Some of them come through Ssu-mao and Kêng Hung; some come to Möng Lem, on our Mang-Lön border; some come through Lungling and Nam-hkam; and some come through Yungch'ang and T'êngyüeh to Bhamo. Fifty years or more ago the route most used was the old Ambassador's route, the road which follows the line of the Mandalay-Lashio Railway, and goes on to cross the Salween at the Kunlông ferry, and pass up the valley of the Nam Ting. At that time probably half the Chinese caravans coming to Burma used this route. The ferry at Kunlông was very busy, and there was quite a considerable Burmese settlement on the island in the Salween. Now there are only two or three dug-outs at the ferry, the island is deserted, and Kunlông village is an insignificant place. The disuse of the road began about half a century ago, when the Chingpaw moved south and seized the hills overlooking the Kunlông ferry. They robbed and blackmailed the caravans until the road was given up. We have restored orderliness and good behaviour amongst the Kachins, but we have done nothing on the other side of the Salween. There our Wa tribesmen occupy the hills overlooking the Namting valley on the south, and menace traders with the loss of their heads. The Chinese authorities have lost all interest in maintaining order, and have neither guard stations nor patrols; consequently bands of cattle thieves have established villages in parts of Mōng Ting and Mōng Hkawn, near the old caravan route, and the result is that all trade has ceased, and the only people who use the Kunlông ferry are the Chinese of our frontier district of Kokang, who send an occasional caravan westwards, and the Chinese Mohammedans of Pang Lông, who despatch perhaps one in a year.

But the old route would very soon be resumed if we were to continue the railway from Lashio to the Salween, and up the Nam Ting Valley to some point in Chinese territory. A terminus there would in a short time pass all the caravans. Those from Ching-tung and south-west Yünnan, which now make their way by Ssu-mao to Kèng-tung, would come to the rail-head, and so would the caravans from Tali and Yungch'ang. The mere avoiding of the steamy valley of the Salween and of the desperate climb of six thousand feet up from the river, on the road from Yung-ch'ang to T'êng-yüeh, would be sufficient to determine them in favour of the southern route. The road, in addition to the bald fact of the climb, is in many places a simple staircase, hewn out of the solid rock. No beasts of burden, except the goat-like Chinese mules and ponies, could get over it. The point which should be aimed at is at present uncertain, because only one

route has been surveyed, and that in a very sketchy fashion. This route was indicated by the valley of the Nam Ting, which carries it right up to the Mèkhong watershed. It was first traversed by Captain H. R. Davies, a very capable officer of the Indian Intelligence Department. His object was to get to Tali-fu, and he, therefore, took the shortest way there. The interim terminus which he suggested was either Shunning-fu or Yün-chou, but, if it is intended to carry the line on farther, the descent from here to the Mèkhong by one stream and the ascent on the other side to Tali-fu would be very formidable. A better line would seem to be to leave the Nanting valley at some point short of Shunning-fu and to cross over to the Nam Hsüng valley. The Nam Hsüng is a very considerable river, which would take the railway with no great difficulty down to the Mèkhong.

Disadvantages of Bhamo-T'êng-yueh Line.

This railway would be infinitely better worth constructing than the line which it is seriously talked of making to T'êng-yüeh from Bhamo. This railway would find no very formidable difficulties in its construction, but it would touch the merest edge of the province of Yünnan; it could not be carried beyond that place except by the construction of the Mont Cenis tunnels and Menai bridges with which Colborne Baber confronted prospectors a quarter of a century ago; it would not attract the caravans from the south-western part of the Yünnan; and, finally, it would not connect with any of the existing lines in Burma, but would end at Bhamo, where the river navigation is becoming more and more difficult every year in the season of low water. The extension from Lashio, even if it went no further than the limit of British territory on the other side of the Salween, would attract caravans from all over western Yünnan; it would connect with the Burma railway system, and it would convert a line, which at present is worked at a serious loss, into one with very great hopes for the future. It would, moreover, give the Shan States a route for the export of its goods to China by a back door, as the Southern Shan States Railway would give one by its front door, in place of the painfully inadequate outlets which the States now have. For this reason the proposed Bhamo-T'êng-yüeh line is a very dangerous temptation, because it diverts attention and capital from the true route. It would probably put off the construction of the Kunlông Railway for years, and would substitute a route ending in a *cul-de-sac* for one having the whole Chinese Empire in front of it. For this reason, a proper expert survey of the country between the Salween and the Mèkhong is necessary, and a further survey of the route through Hsen-wi, by the watershed of the Salween and the Irrawaddy, up the valley of the Nam Tu, is wanted, instead of the present very costly line surveyed down the valley of the Nam Kek, and up the banks of the Salween to the Kunlông ferry.

We are accustomed to talk patronisingly of the way in which the French manage their colonies; but in the way of railway construction they are proving much more enterprising than we are. The deadly sub-montane country between Laokai and Mêng-tzu has killed great numbers of coolies and navvies, and has seriously retarded the construction of their line towards Yünnan-fu; but it is progressing steadily, and will do so rapidly when the highlands of Yünnan are reached.

Improvement of Water Communications.

But it is not merely in the way of railway enterprise that the French give us an object-lesson. They have also done a very great deal to utilise the Mèkhong as a water-way, whereas we have done absolutely nothing with the Salween river which in the same latitudes is a larger river than the Mêkhong. It is true that the *Hat-gyi*, the great rapids, ten miles below the mouth of the Thaungyin, are quite unnavigable, and that the rapids extend over a distance of more than ten miles. But it would be quite possible to construct a light railway to pass these rapids, as the French have done at the rapids of Hkawn, or Li-pi, with a 3½ mile railway across the island of Khong. These Hkawn rapids are quite as formidable though of a different character from the *Hat-gyi* of the Salween. In the Salween the rapids are formed by the presence of bars of rocks stretching right across the river, with falls of from five feet up to twenty feet or more. In the Hkawn rapids a number of islands break up the Mèkhong into a series of channels, which in the season of low water are studded with rocks, and the total fall is estimated at sixty feet. The French had made the rapids of Preapatang, some distance below, navigable by means of extensive blasting

operations, and they continued these at the Hkawn rapids. But it was found that in addition to the magnitude of these works, they were likely to seriously reduce the depth of water in the channel above, so the blasting work has stopped and a portage was substituted. The result is that French-built launches go up to Suvannakek and Wying Chan (Vientian), and goods can go on from there to Luang Prabang and Chieng Khong by native boats. Long reaches are practicable for steam launches, and if the upper, less formidable rapids are blasted, it is not improbable that steam launches will be able to go up past Luang Prabang and Chieng Khong to Chieng-hsen and our frontier. The work of the French is all the more public-spirited and praiseworthy, because it is admitted in the Reports that the trade is in the hands of Chinamen, Germans, and Swedes.

In the case of the Salween, a not inconsiderable existing boat traffic shows us the line we ought to follow. Every year a number of trading boats, simple dug-outs, go down from Mawkmai and from the Karen-ni States to the village of Kyaukhnyat, in the Salween hill tracts. There the goods are landed and taken over a ridge to Papun, whenever they go down the Yônsalin river to its junction with the Salween and so ôn to Maulmein.

If a light hill railway, worked by a power station established on the Salween, were built, steam launches put together at Kyaukhnyat, would have a clear stretch of the Salween between two and three hundred miles long before them and would draw practically the whole trade of the Karen-ni, Mawk-mai, Möng Nai and Möng Pan States. Inspection of the formidable Tang Kao-tek rapid in the Möng Pan State might result in the discovery that it could be made navigable by means of blasting operations, and if this were effected, another rapid, the Tang Löng, would offer no very serious difficulties, and launches would reach the Kaw ferry, where the main Government road crosses the Salween. The advantage in rendering Kèngtung more accessible and in reducing the present enormous cost of rationing the garrison there would almost alone seem to justify the undertaking, but so far nothing in the way of a hydrographic survey of the river above Kyaukhnyat has been undertaken. A flotilla of the kind would in no way interfere with the prospects of the railway, and would probably add considerably to the commercial activity of the Port of Maulmein.

Question of Revenue.

Twelve years ago a paper was read before this Society by Sir Herbert Thirkell White, the Lieutenant-Governor-designate of the province. He referred to the care and cheapness with which the Shan States were governed, and to the interesting character of the experiment which was being tried. The experiment still goes on. The States are not feudatories, but actually part of British India. The chiefs have the power of life and death, and so long as their actions are in conformity with justice, equity, and good conscience they have practically unlimited power in the management of their States. The chiefs are under the guidance of the Superintendents, and have to obey their orders if occasion should arise to issue them. Hitherto practically nothing but advice has been required, and the country has remained quiet and wonderfully free from crime of a serious description. The number of political officers in the States has slightly increased, but the garrison remains the same in number, and military police have, within the last month, been substituted for the last remains of the sepoy garrison. The Shan States have always been very cheaply held, and the expense is no greater now than ever it was, but the tribute received by no means covers the expenditure. It does not seem likely that it will for very many years, unless we provide them with communications which will enable them to develop the very considerable potential wealth which at present tantalises them. The wants and desires, and even the needs of the people, have vastly increased since we took over the States eighteen years ago. Peace has been completely established, internal communications have been made comparatively easy, partly by Government, and very considerably more by the works undertaken by the chiefs. But the wealth of the country has only so far increased as is implied by the establishment of a stable Government, and there are signs that it is now almost stationary.

Great numbers of the people have paid visits to the plains, and have seen the constantly increasing prosperity of the towns and villages of Burma. All the chiefs have been to durbars in Mandalay or Rangoon. Seven of them went to the Imperial Durbar at Delhi. There they saw what wealth can do, and they acquired a taste for expenditure without any increased means of meeting it. There are not wanting signs that they are endeavouring to get more revenue out of their people than the

people can afford, or the sanctioned budgets allow. At the same time the people have discovered new outlets for their money, and have acquired new tastes. They know that there is a market for their potatoes, if they can get them down for a reasonable price; they know that they could make large profits if they could get their wheat to the railways. They believe that Burma is more wealthy than they are, simply because it has railways. Therefore, the whole population, chiefs and people, clamour for a railway as the only hope of the Shan States, and there are not wanting people who believe that the building of the railway would be a very profitable speculation for ourselves, although it cannot be proved by figures.

DISCUSSION.

The CHAIRMAN thought all would agree with him that they had listened to a most interesting paper. Sir George Scott had not only given a succinct history of the Shan States, their customs and their present condition, but he had made some very useful suggestions for the future. The author had quoted the statement that the acquisition of the Shan States on the part of the British nation was an interesting experiment; it was by no means the first of its nature that had been conducted, and he (the Chairman) trusted that it would prove no less successful than its predecessors. About ten years ago, at the Society of Arts, it had been suggested by a predecessor of his that Sir George Scott should put into a paper the results of his observations and of his work, and the treat the author had given them that afternoon was well worthy of the suggestion that was then made. They were all aware that Sir George Scott belonged to that great body of men who had shown both courage and presence of mind in the face of sudden and serious difficulties. Indeed, if he had not shown that courage and presence of mind on a certain occasion, it was doubtful whether they would have had the privilege of listening to him that afternoon. The great interest which had always been taken by this country and by our representatives in the peoples in their care, in their histories and their customs, was an evidence of the qualities which had enabled Britain, not merely to govern its various dependencies and colonies, but to draw to our rule not only the respect, but the sympathy and affection of the subject races of the Empire. He trusted that the result of the paper would be to deepen and to emphasise that interest which the great mass of the people of the British nation felt in the experiments which were going on continually throughout the Empire.

Sir FREDERIC W. R. FRYER, K.C.S.I. (late Lieutenant-Governor of Burma), thought that they had been very fortunate in getting Sir George Scott to read a paper on the Shan States, for he did not know of any English officer who knew more about them. He had served both in the Northern and Southern Shan States, and had always taken a great interest in the people and in the country, and the result of his labours had been made very clear that evening. He had told them that when the British assumed the government of Upper Burma the work of pacifying the Shan States was a very easy one, and that the British officers had only to appear in the different States for them to submit. His (Sir Frederic Fryer's) recollection of that time, however, was not quite exactly the same as that of the author. His (the speaker's) impression was that the work was one of considerable difficulty, and the fact that it was accomplished with so much ease redounded very greatly to the credit of the officers who were charged with the pacification of those States. Amongst those officers he was sure none deserved more credit than Sir G. Scott. It would have been very interesting if the author had told them something of his expeditions into the country of the Was, and also something of his experiences on the three Boundary Commissions on which he served. Speaking for himself, he knew he had been very anxious sometimes as to what would happen to Sir George Scott when he plunged into those wild countries. On several occasions he had met with very serious resistance, and it was only through the courage and presence of mind of Sir George Scott and the officers who served with him that they were able to avoid serious misadventure. On one occasion in the Wa country they were attacked by a very large force, and only emerged after very serious fighting with very great difficulty. But the audience had not been told any of those things; he supposed that Sir George Scott was too modest to tell them of the very serious difficulties he had to overcome in the course of his service in the Shan States. He (the speaker) had visited the country described on several occasions, and could endorse all that the author had said about the necessity for a railway to the Southern Shan States. He was himself very much impressed with that necessity, and, with some difficulty, procured sanction to have a survey made of the railway. The survey was not finished in sufficient time for him to procure the sanction of the Government of India to begin the construction of the railway, but he had heard from his successor, Sir Hugh Barnes, that he had strongly advocated its commencement. Sir Hugh Barnes had also stated that the former trade returns were exceedingly faulty, and that he hoped to be able to show that the traffic was very much greater than was supposed. Personally, he (Sir Frederic Fryer) was convinced that the railway would pay, and he was of opinion that, even if it did not pay, it ought to be constructed in order to remove the many and great disadvantages which the people of the Southern Shan States suffered from. The line to the Northern Shan States was

never expected, by any person who knew anything about it, to be remunerative, having been made solely to open out trade with China. When it was found that the line was exceedingly expensive and that the advisability of continuing it into China was open to doubt, the work was stopped at Lashio. A line running to Lashio was no good as far as trade was concerned; it was of some slight use politically, as it opened out the Northern Shan States. He was informed that the line did pay as far as Maymyo, but beyond that it ran mostly through a barren and uninhabited country, and unless it was continued to China he did not think there was any prospect of it ever paying within any measurable distance of time. With reference to the line which was contemplated from Bhamo to Tengueh, he had a certain amount to do with it before he left Burma, and although it was quite possible to make a line to Tengueh, beyond that place the country was impracticable, except at an expense which would be prohibitive. He was glad to say that the Shans had now practically settled down as peaceful subjects of the British Empire, and it would be very instructive if those present could see the sons of the Shan chiefs in the school at Taungyi, which had been a great success. He was quite sure the influence of education would spread over the Shan States, and when they got their railway—which they must do in time—the prosperity of the Shan States would be restored to what they had been told it was in former times.

Major H. R. DAVIES thought that to those who knew the Shan States it must have been a great pleasure to hear the country and its inhabitants so well described by the author. He thought he could say without fear of contradiction that there was no greater authority on the subject than Sir George Scott. He was glad to hear him allude to the fact that the Shans were a very numerous and widely-spread race. The few people in England who had heard of the Shans looked upon them rather as some small hill tribe on our eastern frontier; but, as the author had said, they occupied the whole of Siam, and what were now called the Shan States, and they also spread out a great deal westwards as far as Assam. Besides this they formed a very large part of the population of four of the Chinese provinces, viz., Yunnan, Kwei-chou, Kwang-si, and Kwang-tung, which were in the south-west corner of China, but. as far as three out of the four were concerned, they had not been explored enough at present for them to know how much Shan population there was in them. Even if they had accurate information on that point it would not give an adequate idea of the real extent of territory that the Shan race originally occupied. He thought that a great many of the Chinese of southern and western China had really more Shan blood in them than they had Chinese. Those who knew the Shans would have noticed the great facial and physical resemblance between them and the southern Chinese. If one were to suggest to a Cantonese Chinaman in the present day that his ancestry went back to the Shans, he would consider it an insult. He thought, however, that this was only a proof of the very thorough way that the Chinese could assimilate foreign tribes. It was recorded in Chinese history that the whole of the south and the west of China was originally inhabited by non-Chinese tribes, and it was only within the last few hundred years that the Chinese had penetrated to any great extent to a considerable part of the country. They had penetrated partly by conquest, followed by the planting of soldier colonists among the Shans and other tribes. These soldier colonists had naturally taken wives from the country, and the result had been a mixed race with a great deal more aboriginal blood in them than Chinese blood. Moreover, peaceful emigrants from time to time went from China and settled amongst these tribes, pressed on probably by the difficulty of getting a living in the more populous parts of China, and the influence of China had gradually spread in that way. All this was not mere theory, because the process could still be seen going on in Western China. In Yunnan up to the present day one could see tribes in all stages. There were some of them who still retained their language and customs, and knew no Chinese; there were others who, as Chinese influence spread, gradually began to talk Chinese and adopt Chinese customs. The final result was a most correct Chinaman, who, after a generation or two, would quite forget that he had any other ancestry than the Chinese; in fact, he would resent it if anyone suggested the contrary. The real independent Shans were still under their own chiefs and spoke their own language. In other places one found a mixed population of Shans speaking Shan, and Chinese speaking Chinese. In that case the Shans were generally under a chief of their own, but the Chinese of the place were under the district official of China. A little later they all became real Chinamen, and the place would become a Chinese district. There was one thing that had tended to save the Shans from being swamped by the Chinese, viz., the climate. The Chinaman of Western China —he could only speak of Yunnan—was accustomed to a height of 6,000 feet, and to a very pleasant country, and thought no place was fit to live in that was under 4,000 feet. Consequently, the Shans were left undisturbed in the lower-lying valleys. As Sir George Scott had mentioned, both in the Shan States and in Yunnan there were a great number of other tribes besides Shans. He thought it was a great pity that some individual inclined that way, or some learned society, did not study those tribes. The philology of that region was well worth taking up, because for the languages of that part of the world there still remained to be done what Max Müller and others had done for the Aryan language. So far this had been left principally to travellers and frontier officials, who had not time to take the matter up thoroughly. If any

learned society would undertake this work he thought they would be well repaid.

On the motion of the CHAIRMAN, a hearty vote of thanks was accorded to Sir George Scott for his admirable paper.

INDUSTRIAL ALCOHOL.

The Report of the Departmental Committee on Industrial Alcohol (Cd. 2,472) has just been issued and is both interesting and important. The Committee was appointed by the Chancellor of the Exchequer "to inquire into the existing facilities for the use, without payment of duty, of spirits in arts and manufactures, and in particular, into the operation of Section 8 of the Finance Act of 1902, and to report whether the powers conferred upon the Commissioners of Inland Revenue by this section permit of adequate facilities being given for the use of spirits in manufactures and in the production of motive power, or whether further facilities are required; and if it should appear to the Committee that the present facilities are inadequate, to advise the further measures to be adopted, without prejudice to the safety of the revenue derived from spirits, and with due regard to the interests of the producers of spirits in the United Kingdom." In interpreting the terms of reference the Committee considered that the main objects of their inquiry were to ascertain the extent to which alcohol is, or might be, employed in arts and manufactures, or in the production of heat, light, or motive power, and to determine the conditions of greatest freedom that could be accorded to its use for these purposes, consistently with adequate safety to the revenue derived from spirit as an article of human consumption.

The use of methylated (denatured) spirit duty free was first authorised in 1855 by the Act 18 and 19 Vict., c. 38. The present law on the subject is contained in the Spirits' Act, 1880, as amended by the Customs and Inland Revenue Act, 1890, and Section 8 of the Finance Act, 1902. Up to 1855 spirit could not be used duty free by the public under any circumstances. From that year until 1861 it could be used duty free for manufacturing purposes only, if methylated according to the prescribed process. From 1861 to 1891 spirit could be used duty free for any purpose other than consumption directly or indirectly as a beverage, or internally as a medicine, provided it was mixed with wood-naphtha to the extent of one-ninth of its volume. But if used in large quantities, as for manufacturing purposes, it could not be purchased from a retailer of methylated spirit but only from a methylator, and the user was subject to Excise supervision. From 1891 to 1902 the use of this kind of methylated spirit was confined to manufacturing purposes, subject to the same conditions as before, while for general purposes a spirit consisting of the above spirit with an addition of ·375 per cent. of mineral naphtha, and known as "mineralised" methylated spirit, was brought into use. It is only in this spirit that retailers are permitted to deal. Since 1902 the two kinds of methylated spirit have continued to be used as before. But an alternative to their use has been opened to manufacturers under which spirits may be employed after being subjected to some special process of denaturing, appropriate to the particular industry, or possibly even in a pure state, should circumstances be held by the Board of Inland Revenue so to require.

The Committee say that advantage has been taken of the Act of 1902 by a certain number of manufacturers, "but in examining the witnesses that have come before us, we have been surprised to find in some quarters a very inadequate acquaintance with its provisions, and much failure to appreciate its significance." The "ordinary" methylated spirit is open to certain objections as a material or instrument of manufacture. In a few cases it is unsuitable owing to the chemical properties, or of the smell of the wood-naphtha it contains. And it is always open to the disadvantage that it is somewhat heavily enhanced in cost as compared with pure spirit. For not only does the wood-naphtha, which must be present to the extent of 10 per cent., cost more than double the price of the equivalent quantity of spirit, but now and again it tends to make the mixture less efficient for the purpose in view than it would be without this ingredient. It was to meet these objections that legislation was undertaken in 1902, and the Committee consider that Section 8 of the Finance Act of that year does all that is possible in respect of the character of the spirit. It has removed all difficulty in the way of procuring a spirit suitable in character for any industrial purpose. It has also to some extent lessened the objection on the score of cost, inasmuch as the special processes of denaturing authorised by the Board of Inland Revenue are becoming less expensive to the manufacturer than is the case with "ordinary" methylated spirit. On the other hand the cost of these processes is enhanced by the charges for Excise supervision.

But the cost of denaturing touches a part only of the question of the price of the spirit used for industrial purposes. A more potent influence on price is found in the conditions under which spirit can alone be manufactured in this country. The duty on spirit used as a beverage in the United Kingdom is very heavy, and in imposing this duty it is essential to the protection of the revenue to impose on the manufacture of spirits such restraints as may be necessary to prevent any spirit from escaping payment of duty. A consequence of such restraints is to cause an appreciable enhancement of the cost of manufacture, the measure of which is not susceptible of positive determination. For its purpose the Committee assume an enhancement of the cost of producing plain British spirits by 3d. the proof gallon, or an increase of about 50 per cent. on the cost that would otherwise prevail in the production of industrial

alcohol. The final result upon the cost of industrial spirits of all the measures taken to protect the revenue is given by the Committee as follows:—Spirit used in manufacture is commonly about 64 over-proof, and is plain spirit. The price of a bulk gallon of the spirit is about 5d. more than it would have been but for Excise restrictions. The cost of methylating is put at between 3d. and 4d. per bulk gallon, so that of the price eventually paid by the manufacturer, which at present may be taken at from 20d. to 22d. per bulk gallon for large quantities at wholesale price, about 8½d. is attributable to precautions on behalf of the revenue. In the opinion of the Committee, the conditions in which the spirit must be used, and the price at which it can be procured, affect different industries in very varying degrees. Either consideration may be of vital importance to a particular industry, but speaking generally, and taking the whole range of industrial enterprises employing alcohol, the question of price is infinitely the more important of the two. A difference of, say, 6d. per bulk gallon in the price of alcohol may make all the difference between profit or loss in the carrying on of an enterprise.

The coal tar colour industry figured very prominently in the discussion which led up to the appointment of the Committee. It was said that this industry, which originated in this country, and at one time flourished here, has been lost to us very largely, if not mainly, by reason of the obstacles in the way of a cheap and untrammelled supply of alcohol. The Committee went into the evidence very carefully, and are satisfied that, "regarded as a statement of historical fact, the assertion that the coal tar colour industry has been lost to this country on account of obstacles to the use of alcohol is destitute of substantial foundation." In the earlier days of this industry alcohol was used almost wholly as a solvent, and for that purpose methylated spirit is suitable. Moreover, when alcohol first began to be used as a constituent of dyes, and until some time after the decadence of the industry in this country had become marked, the price even between duty free and duty paid alcohol was a matter that could practically be left out of consideration. In the opinion of the Committee "the cause which predominated over all others was the failure of those responsible for the management and for the finance of the industry here, during the years 1860-80, to realise the vital importance of its scientific side, and their consequent omission to provide adequately for its development on that side." In at least 75 per cent. of the whole industry alcohol does not enter into account even now, and these branches could be prosecuted in this country, as indeed they now are, whatever the conditions in regard to the use of alcohol might be. "Nevertheless," say the Committee, "even where alcohol is not immediately required for the manufacture of a dye stuff, the utilisation of waste products, and the development of new methods, may be hampered by the want of alcohol; while for the dye stuffs for which alcohol is essential, its price and the conditions of its use are matters of great moment. We are of opinion, therefore, that if the hope is to be entertained of recovering any considerable portion of this trade more favourable conditions must be established in respect of the use of alcohol."

The evidence as to whether in the smokeless powders industry ordinary methylated spirit is unsuitable or detrimental in character is described by the Committee as "conflicting and inconclusive." But the question of the price of spirit and ether is one of vital importance to the manufacturer of smokeless powder, of which nitro-cellulose is a constituent. The quantity of alcohol used, either directly in the form of spirit, or indirectly in the form of ether, for the production of one pound of this powder, is very large. The witness gave the Committee to understand that a difference of 6d. per gallon in the price of spirit would make a difference of 7d. per lb. in the cost of the powder produced, and it is manifest that a much smaller difference than that would turn the scale between profit and loss. In pharmaceutical products again alcohol plays a very important part. In Section 4 of the sub-committee's report the subject is very fully treated. The Committee content themselves with observing that "for a large and probably increasing number of substances, such as the synthetic perfumes, antipyrine, phenacetin, sulphonal, and so on, alcohol at a price not in excess of that at which it stands in competing countries, and usable under conditions not inimical to to the quality and character of the compounds provided, is essential to the existence of the industry." The production of ether again has become a most important industry, and seeing that it requires much more than a gallon of strong spirit to produce a gallon of ether, the price of spirit is manifestly a condition of primary moment to this industry. And so with artificial silk. This industry is not at present prosecuted in this country, but it employs many thousands of workpeople on the Continent. Here again the price of alcohol is a consideration of vital importance, as the combined ether and spirit required to produce one pound of the finished article represents nearly a gallon of strong spirit.

The general conclusions arrived at by the Committee may be summarised as follows:—(1) That used for general and universal purposes "mineralised" methylated spirit is quite satisfactory both to the revenue and the public in respect of character, and that at present no better method of denaturing is available. As to price, the regulations in regard to distribution might be appreciably relaxed in respect to the quantities that retailers may keep in stock, or may sell at any one time to a customer. (2) That where spirit is used for industrial purposes the Finance Act of 1902 works well. (3) That something more is required in order to place spirit used as an instrument or a material of manufacture on a footing satisfactory in the matter of cost. Anything in the nature of a bounty is undesirable, but seeing that on the price of spirit the very existence of certain

industries may depend, and that for all industries using alcohol the price of spirit is an important factor for the future of trade that lies outside the home market, it is desirable to make such arrangements as will free the price of industrial spirit from the enhancement due to their indirect influence of the spirit duties. The only way to do this is by granting an allowance on such spirit at such rate as may from time to time be taken as the equivalent of the increase in cost of production due to revenue restrictions. At the present time the rate is taken at 3d. per proof gallon for plain spirits, and the allowance would accordingly be at this rate, and should be paid equally on all industrial spirit whether it be of British or foreign origin. (4) That "ordinary" methylated spirit should contain only 5 per cent. of wood-naphtha, instead of 10 per cent. (5) That no charge should be made on manufacturers for the regular attendance of Excise officers to supervise denaturing operations, or the use of denatured spirit, in factories taking the benefit of Section 8 of the Finance Act, 1902. (6) That in the manufacture of fine chemicals and pharmaceutical products spirits specially denatured should be allowed only where the manufacture is kept entirely separate from the manufacture of tinctures and other preparations in which spirit remains as spirit in the finished product. (7) That an allowance be granted to all industrial spirit whether of British or foreign origin at the rate from time to time prevailing for the allowance to British plain spirits on export. (8) That the imported methylic alcohol be relieved from the obligation to pay the surtax imposed by Section 8 of the Finance Act, 1902, and that methylic alcohol be given favourable treatment in the matter of denaturing.

GENERAL NOTES.

PRIZES FOR DYEING.—The Council of the Society of Dyers and Colourists announce that funds have been placed at their disposal for distribution in the form of prizes for the solution of technical problems. The following prizes are now offered:—1. £10 for a satisfactory systematic tabulation of the reactions of dyestuffs on the fibre, and a comprehensive scheme for their identification on dyed fabrics. The scheme should include the principal colouring matters dyed singly on all fibres for which they are employed. Competitors may adopt any method of classification they think desirable, but it is suggested that one or two reagents only be used as group tests, other reagents being subsequently applied for distinguishing the individual colours in a particular group. 2. £10 for a reliable method of distinguishing between unmercerised and mercerised cotton of various qualities, and for the estimation of the degree of mercerisation without reference to lustre. 3. £20 for a full investigation of the causes of the tendering of cotton dyed with sulphide blacks, and the best means of preventing such tendering. 4. £20 for a satisfactory standardisation of the strength and elasticity of cotton yarns of various qualities and twists in the grey and bleached conditions. 5. £20 for a full investigation of the average degree of tendering brought about in cotton yarn of various qualities by—(a) cross dyeing with acid colours; (b) dyeing aniline black; and (c) various other dyeing processes, with the object of fixing standards for the trade. Further information can be obtained from the hon. secretary, Mr. Ernest T. Holdsworth, Westholme, Great Horton, Bradford.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

MAY 3.—"Recent Excavations in Rome." By MRS. BURTON-BROWN.

MAY 10.—The Native Races of the Unknown Heart of Central Africa." By VISCOUNT MOUNTMORRES. J. CATHCART WASON, M.P., will preside.

MAY 17.—"The Use of Wood Pulp for Paper Making." By S. CHARLES PHILLIPS, M.S.C.I.

MAY 24.—"Modern Lightning Conductors." By KILLINGWORTH HEDGES, M.Inst.C.E., Hon. Sec. to the Lightning Research Committee.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

MAY 11.—"The Manufactures of Greater Britain.—III. India." By HENRY JOHN TOZER, M.A.

MAY 18.—"Plague in India." By CHARLES CREIGHTON, M.D. SIR DENNIS FITZPATRICK, K.C.S.I., will preside.

COLONIAL SECTION.

Tuesday afternoons at 4.30 o'clock:—

MAY 23.—"The Cape to Cairo Railway." By SIR CHARLES H. T. METCALFE, Bart., M.Inst.C.E.

APPLIED ART SECTION.

Tuesdays, at 4.30 or 8 o'clock:—

MAY 2, 4.30 p.m.—"The Monumental Treatment of Bronze." By J. STARKIE GARDNER, F.S.A. SIR GEORGE BIRDWOOD, K.C.I.E., C.S.I., will preside.

MAY 16, 4.30 p.m.—"Excavation of the Oldest Temple at Thebes." By H. R. H. HALL, M.A.

[Mons. Lalique (of Paris) is unable to read his paper on "Popular Jewelry" which was announced for this date, and Mr. Hall has kindly undertaken to read the above paper in its place.]

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

ALAN S. COLE, C.B., "Some Aspects of Ancient and Modern Embroidery." Two Lectures.

LECTURE I.—MAY 1.—Application of the term embroidery to methods of working ornamentally with threads—Specimen of Egyptian embroidery, 1450 B.C.—Correspondence of its method with that of much Greek and Roman embroidery—Embroidery as an occupation in Greek houses, and as a trade in Rome—Embroidery in Benedictine monasteries and convents—The relation of illuminations in MSS. to designs for embroideries—The Dalmatic of Charlemagne, and suggestions of its figure designs being derived from Frankish illuminations of the 9th century—Comparison of designs for Bayeux tapestry, with outline figure drawings in MS. of Ælfric's Pentateuch.

LECTURE II.—MAY 8.—Embroidery in England, 12th and 13th centuries—MS. illumination, painting and embroidery as secular arts in 13th and 14th centuries—Influence of work in one art craft (the Goldsmiths') on that in another (Embroiderers')—Types of ecclesiastical English embroidery 13th, 14th, and 15th centuries, compared with contemporary illuminations in MSS. — Designs for English embroidery gradually affected by developments in ornamental weaving abroad—Symmetrical and floral patterns taking the place of designs with figure subjects having an epical or story-telling interest—English secular embroidery of the 16th and 17th centuries—The "conceits" in embroidery of the Elizabethan and Stuart periods—Embroidery in costume in 16th, 17th, and 18th centuries—Aspects of modern English embroidery—the designs for it: different phases of its practice, for ordinary trading purposes, for more limited purposes, and for special occasions in connection with technical instruction—Embroidery.

HENRY WILLOCK RAVENSHAW, Assoc. M.Inst.C.E., Mem.Fed.Inst.Min.Eng., "The Uses of Electricity in Mines." Two Lectures.

May 15, 22.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MAY 1...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Mr. Alan S. Cole, "Some Aspects of Ancient and Modern Embroidery." (Lecture I.)

Farmers' Club, 2, Whitehall-court, S.W., 4 p.m. Prof. Wrightson, "The Expenses and Commensurate Advantage of Turnip Cultivation in Southern England."

Royal Institution, Albemarle-street, W., 5 p.m. Annual Meeting.

Engineers, in the Theatre of the United Service Institution, Whitehall, S.W., 7½ p.m. Mr. Ernest R. Mathews, "The Parade Extension Works at Bridlington."

Chemical Industry (London Section), Burlington-house, W., 8 p.m. Prof. Chiri Otsuki, 1. "The Study of the Action of Hydrogen Peroxide on a Photographic Plate in the Dark." 2. "The Influence of the Length of the Time of Development on the Degree of Darkening of the Photographic Plate."

British Architects, 9, Conduit-street, W., 8 p.m. Annual Meeting.

Victoria Institute, 8, Adelphi-terrace, W.C., 4½ p.m. Mr. Edward P. Frost, "The Influence of Physiological Discovery on Thought,"

TUESDAY, MAY 2...SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Applied Art Section.) Mr. J. Starkie Gardner, "The Monumental Treatment of Bronze."

Royal Institution, Albemarle-street, W., 5 p.m. Prof. L. C. Miall, "The Study of Extinct Animals." (Lecture II.)

Central Chamber of Agriculture (at the HOUSE OF THE SOCIETY OF ARTS), 11 a.m.

Pathological, 20, Hanover-square, W., 8½ p.m.

Photographic, 66, Russell-square, W.C., 8 p.m. Mr. Redmond Barrett, "Retouching and Improving the Negative."

Zoological, 3, Hanover-square, W., 8½ p.m.

WEDNESDAY, MAY 3 SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Ordinary Meeting.) Mrs. Burton-Brown, "Recent Excavations in Rome."

Royal Archæological Institution, 20, Hanover-square, W., 4 p.m. The Viscount Dillon, "The Rack."

British Archæological Association, 32, Sackville-street, W., 4½ p.m. Annual Meeting.

Obstetrical, 20, Hanover-square, W., 8 p.m.

THURSDAY, MAY 4...Electrical Engineers (at the HOUSE OF THE SOCIETY OF ARTS), John-street, Adelphi, W.C., 8 p.m. Discussion on Mr. A. M. Taylor's paper, "Standby Charges and Motor Load Development."

Linnean, Burlington-house, W., 8 p.m. 1. Mr. A. G. Tansley, "Ecology: its present position and probable development." 2 Mr. R. N. Rudmore Brown, "The Flora of Gough Island."

Chemical, Burlington-house, W., 8 p.m. 1. Mr. H. D. Dakin, "The synthesis of substances allied to adrenaline." 2. Mr. J. Johnston, "Methylation of p-aminobenzoic acid by means of methyl sulphate." 3. Mr. J. M. Wadmore, "Some notes on sodium alum." 4. Messrs. M. O. Forster and H. E. Fierz, "Camphoryl-ψ-semicarbazide."

Royal Institution, Albemarle-street, W., 5 p.m. Prof. Sir James Dewar, "Flame." (Lecture I.)

United Service Institution, Whitehall, S.W., 3 p.m. Lieut.-Col. H. A. Iggulden, "The Tibet Expedition."

Civil and Mechanical Engineers, Caxton-hall, Westminster, S.W., 8 p.m. Mr. J. C. Osborne, "Card-Indexing and Filing."

FRIDAY, MAY 5...Royal Institution, Albemarle-street, W., 9 p.m. Professor H. E. Armstrong, "Problems underlying Nutrition."

Art Workers' Guild, Clifford's-inn Hall Fleet-street, E.C., 8 p.m. Paper on "The Work of Reynolds."

Geologists' Association, University College, W.C., 8 p.m.

Junior Institute of Engineers, Westminster Palace Hotel, S.W., 7 p.m. Mr. Leslie C. Lambert, "The Influence of Depth of Water on Speed of Vessels." Mr. James N. Boot, "Condensing Plant."

Philological, University College, W.C., 8 p.m. Annual Meeting.

Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m.

SATURDAY, MAY 6...Royal Institution, Albemarle-street, W., 3 p.m. Prof. Marshall Ward, "Moulds and Mouldiness." (Lecture I.)

Journal of the Society of Arts.

No. 2,737. VOL. LIII.

FRIDAY, MAY 5, 1905.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

NOTICES.

NEXT WEEK.

MONDAY, MAY 8, 8 p.m. (Cantor Lecture.) ALAN S. COLE, C.B., "Some Aspects of Ancient and Modern Embroidery." Lecture II.

WEDNESDAY, MAY 10, 8 p.m. (Ordinary Meeting.) VISCOUNT MOUNTMORRES, "The Native Races of the Unknown Heart of Central Africa."

THURSDAY, MAY 11, 4.30 p.m. (Indian Section.) HENRY J. TOZER, M.A., "The Manufactures of Greater Britain.—III. India."

Further details of the Society's meetings will be found at the end of this number.

CANTOR LECTURES.

On Monday evening, 1st inst., Mr. ALAN COLE, C.B., delivered the first lecture of his Course on "Some Aspects of Ancient and Modern Embroidery."

The lectures will be published in the *Journal* during the summer recess.

APPLIED ART SECTION.

Tuesday afternoon, May 2; SIR GEORGE BIRDWOOD, K.C.I.E., C.S.I., in the chair.

The paper read was "The Monumental Treatment of Bronze," by J. STARKIE GARDNER, F.S.A.

The paper and report of the discussion will be published in the next number of the *Journal*.

CONVERSAZIONE.

The Society's Conversazione this year will take place at the Royal Botanic Gardens, Regent's-park, on Tuesday evening, July 4, from 9 to 12 p.m.

The programme of arrangements will be announced in future numbers of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

NINETEENTH ORDINARY MEETING.

Wednesday, May 3, 1905; CARMICHAEL THOMAS, Treasurer of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Cato, W. C., Malvern, Augusta-road, Hobart, Tasmania.
Davis, Charles E., 847, North Church-street, Rockford, Illinois, U.S.A.
Parker, Critchley, Broken Hill-chambers, 31, Queen-street, Melbourne, Australia.
Ruffer, Henry, Menival, Crystal Palace Park-road, S.E.
Sheath, James T. T., 87, City-road, E.C.
Sturgess, Archibald T., M.I.Mech.E., Messrs. Sturgess and Foley, Alcala 52, Madrid, Spain.
Thompson, Charles Herbert, F.C.S., Enville-street, Stourbridge.

The following candidates were ballotted for and duly elected members of the Society:—

Ababrelton, Robert à, P.O. Box 322, Pietermaritzburg, Natal, South Africa.
Kinch, Walter S., Burtholme, Worthington, near Wigan.
Lucchesi, Andrea C., 2, Camden Studios, Camden-street, N.W.

The paper read was—

RECENT EXCAVATIONS IN ROME.

By MRS. BURTON-BROWN.

In 1898 Commendatore Boni began to excavate the Roman Forum for the Italian Government. It may be said, without exaggeration, that all the remains of classic Rome which are most full of significance, and which throw the greatest light upon the Romans, upon the development of their religion, their political institutions, and their life, have been revealed

during the seven years of his work there. The Forum was the centre of every side of the life of the City; its most ancient shrines, its place of political assemblage, its judicial tribunals, and its best shops were all situated in the narrow and marshy valley which first rose into importance as the common market-place of the small villages set upon the hills in the midst of which it lay. Through it passed the great triumphal possessions, and in it every class of Romans assembled for social intercourse. The times of the Kings and of the Republic are those in which the foundations of the Roman power were laid, and in the institutions of those times the pure Roman elements which lay at the base of it are to be traced. The centuries of the Empire shew us a Rome in which foreign influences and importations had modified, and in great part changed, the true characteristics of the Roman, and of his religious and political ideals: it is therefore to the remains of kingly and republican Rome that Signor Boni has striven to reach, and striven with a success which has exceeded all expectation.

It would seem that the Latin tribes entered Italy from the north-east corner, and wandered along the low flat coast, about 1000 B.C. At last they crossed the Apennines and again settled, on the western side of the peninsula, rather upon low hills rising out of the marshes than upon lofty mountain peaks. They would seem to have been originally lake-dwellers, and the name Latin has been derived from *latus*, "the people of the plain." From the small volcanic group of the Alban Hills some of them came westwards to the Septimontium, and communities grew up on the Capitol, the Esquiline, the Palatine, the Quirinal, &c., which, about the eighth century B.C., were united into one city by the chieftain of the Palatine, whom we call Romulus. The villagers met for exchange and barter in the valley of the Forum, and so great was the loyalty of the Romans in later times to the traditions of their city, that for a thousand years that valley remained, in spite of all its inconveniences, the central point of its life. The Sacra Via, the famous path of the triumphs, and the road where Horace strolled with his friends, was at first a track across the marsh, passing along its higher and its sunnier side, and uniting the two chief villages of the Palatine and the Quirinal.

All dwellers upon hills must fetch their water from a spring below, or rather they must send their womenkind to fetch it. Under the steep cliff of the Palatine a copious spring rose to the surface, which the Romans called the fountain of Juturna. From it the first Palatine women carried water in rough earthern jars up to the village, as the women of so many little towns in Central Italy do to-day. When the Romans had learned to dig wells for their water the primitive associations of this spring with the origins of the State gave it a peculiar sanctity in their eyes, and it became a shrine of that nature-worship which held their allegiance so much longer, in its purer and more abstract form, than it did that of the Greeks. The Romans had an implicit belief in the curative powers of water, and what water was so likely to be beneficial

FIG. 1.

CLIVUS SACRÆ VIÆ.

as that of the first sacred pool of their forefathers? A sanctuary of healing grew up around the place, which became a kind of pool of Bethesda of the city. Varro derives the name of Juturam from *juvare*, "because so many sick are wont to seek the aid of the waters." A number of small arched cells behind the pool were found to contain the statues of health divinities, and seemed to have formed a kind of open-air hospital.

The story went that Castor and Pollux, appearing from the sky upon white horses, decided the battle of Lake Regillus in favour of the Romans, and afterwards announced this crowning victory over the Tarquins in the Forum, where they washed their horses in the fountain of Juturna. Their statues were set up at the place, and numerous fragments of these have come to light there. The sacred

pool was placed in the charge of a priesthood, and since it was mainly resorted to by women, this was very naturally a female one. Close beside it stood the hut of the public fire from which the same women might fetch embers to rekindle their own hearths, and which was under the care of the same priesthood, the Vestal Virgins. These were "the daughters of the City," and performed for the State all such duties as in each household were performed by its womenkind. They were present at all ceremonies connected with the harvest, they brought the sacred water for expiatory sacrifices, they cooked the sacred cakes of the mola salsa, and they kept alight the fire upon the City Hearth. It was this intimate connection of theirs with the corporate State which gave them so deep and abiding a sacredness to a Roman mind.

The Hut of the Fire was called the "Aedes Vestæ," and since it was above all the shelter of the hearth of the city, it kept throughout its many successive re-buildings the circular form of a primitive hut, such as we see in the clay hut-urns found in early Latin cemeteries. The dwelling of the Vestals adjoined it, and close to both stood the Regia,* "the royal house," and the dwelling-place of the King and Father of the primitive Family State of Rome. Thus it came about that there grew up in the south-eastern corner of the valley, around the spring, a group of shrines closely connected with the earliest beginnings of the joint city.

In the diagonally opposite, and north-western corner, was the Comitium, or place of political assembling. It was railed off by Tullius Hostilius, who built the first Senate House, or Curia, on the slope of the hill above. In the Comitium stood the platform for orators, which was called the "rostra" because it was decorated with prows of the ships taken in naval warfare. In the Comitium, Boni has explored 23 archæological strata, these being floors laid down one upon another, and each one scattered with relics of the pottery and the sacrifices of the Romans. Several passages from Latin writers agree in stating that there was here, and in close connection with the "rostra," a "Lapis Niger," which marked the site of the tomb of Romulus, which tomb was guarded by two lions of stone (or by one). The famous Black Stone was found in 1899 and is actually a trapezoidal piece of black marble pavement let into the white pavement of the Comitium, undoubtedly in order to hide from view certain ancient and ruined monuments which it covers, while for ever commem-

FIG. 2.

THE REGIA (from "Recent Excavations in the Roman Forum.")

orating their position. In order to discover whether a tomb of Romulus did really exist beneath it, Boni dug under the marble, having supported it on iron props. He found there two bases on which the lions may well have stood, together with two broken columns, the one conical, the other pyramidal, in shape. Around them lay the remains of a great sacrifice, and many votive offerings. Boni's own theory is that during the social wars of the Republic, when the plebeians were attempting to seize a share in the government from the patrician families of pure Roman blood, and when their tribunes appropriated the "rostra" for their own demagogic harangues, the patricians made a violent onslaught upon them. The ancient monuments before the platform were broken, but the plebeians performed a great expiation, and covered down the ruin with black marble brought from Cape Matapan.

FIG. 3.

ARCHÆOLOGICAL STRATA IN THE COMITIUM.

The pyramidal column is covered on all four sides by an inscription, written *boustrophedon*, and in Chalcidic Greek; but, in spite of all efforts, only a very general idea of the meaning of this will ever be gathered, since two-thirds of it are broken away.

The period of the Republic has few remains of importance in the Forum which distinctively belong to it, although it is very clear that the notions of the Romans of that most important time in their history, as to religion and as to political aims, are greatly elucidated by the monuments which have just been described. Pavements and mighty drains of Cato and his contemporaries can indeed be pointed out *in situ*, and the latest discovery is one which must not be forgotten. It is the Lacus Curtius. Ovid remarks that in the spot where the gulf opened and closed upon Márcus Curtius, a pavement had in his time been laid down. This pavement, together with two others beneath it has come to light in the centre of the Forum, and upon it is part of the altar where sacrifice was performed to the Manes of Curtius.

Julius Cæsar determined to put an end to the republic, and to establish an autocracy based upon a wide democratic popularity. As he planned to transform the State, so he transformed the Forum. The buildings in it, whether consecrated to religious or to political uses, had been orientiated according to the sun's course, when they were inaugurated by the augurs. Walls and pavements can be seen in every part of the Forum lying below those of the Empire, and set upon these lines. One by one each was rebuilt or changed by Julius Cæsar and by Augustus, and in defiance of the old customs of inauguration the new imperial Forum grew up, a broad open square following the natural conformation of the valley and the Capitol. This Forum was dominated by the new Rostra of Cæsar, from which the orators addressed the mob assembled in the open space, and no longer the free men of the Comitium. It was lined on both sides by the Basilicæ Julia and Æmilia, and at the further end, appropriately enough, stood the temple of Divus Julius, just behind the altar which Augustus erected on the site of the pyre of the great dictator. The people, as they assembled in the Forum, saw it surrounded by monuments of imperial magnificence, and the lofty temple of Julius, together with the triumphal arch of Augustus, shut the primitive shrines of Vesta, Juturna, and the Regia out of sight and out of mind. In order to enhance his popularity, Julius determined to hold the games on a scale of greater splendour than before. It was difficult, as may well be imagined, to find room for this, and it is now found that he tunnelled its length and breadth by a system of five subterranean corridors. By means of these, theatrical properties, fighters, and wild beasts were brought beneath the arena, and were hauled up to it by small lifts. There are ample traces of the windlasses by which these were worked. The

FIG. 4.

INSCRIPTION ON THE PILLAR UNDER THE BLACK STONE.

FIG. 5.

ROSTRA OF CÆSAR (from "Recent Excavations in the Roman Forum").

corridors when found were quite choked with earth and rubbish, and now that they have been cleared they are the most salient proof which could be found of Cæsar's political aims.

Statius tells us that a colossal bronze equestrian statue of Domitian was set up under that emperor in the midst of the Forum. Its concrete base was discovered recently. On searching it Boni found a block of travertine embedded in the concrete. A small hole in the middle of it contained six vases of a very primitive type, a type indeed which was in use as we have every reason to believe about the eighth century B.C. Their contents comprised some gold ore. We know that Vespasian in laying the foundation-stone of the temple of Jupiter placed in it unsmelted precious metals, and there can be little doubt that we have here the remains of the inaugural votive offering of Domitian's monument, contained in what the Romans called "Vasa Numæ," *i.e.*, vases made in imitation of those actually in use under the King, whom they revered as the founder of the religious institutions of the city.

Outside the Forum a most beautiful monument of Augustus has recently been partially explored by Signor Pasqui, the "Ara Pacis Augustæ." It was dedicated in the year 9 B.C. by the Senate, in commemoration of the victories of Augustus, and of the opening of that golden age of Peace which it was hoped that they might bring to the Roman world. It consisted of an altar of sacrifice raised on a platform, and surrounded by a marble enclosure wall covered with carvings in relief, both on the inner and the outer side. A large number of slabs from this wall have long been at the Villa Medici, others in the Vatican, the Uffizi, and the Terme Museum. Only recently, however, has it been recognised that they were connected, and that they belonged to the Ara Pacis, and in consequence, Pasqui was entrusted with the further exploration of the site from which they came. Many more fragments have come to light as well as the plinth of the wall.

The outer face of the screen had a frieze which represented a procession of majestic and dignified Romans, led by the Emperor Augustus, to do sacrifice at a shrine. They comprise four Flamines and other priests, as well as the ladies of the Imperial Family, and portrait figures of Tiberius, Drusus, and others. The sacrifice is offered by a symbolical figure representing the "Senatus Romanus," at a rustic stone altar. The shrine is shown as that of a graceful reclining woman surrounded by the emblems of fertility. She has been usually explained as "Tellus," but may equally well represent Augustan Peace, surrounded by the accompaniments of Fruitful Earth. The frieze may be regarded as the marble counterpart of the Carmen Seculare, which is filled with rejoicing over the prosperity which was expected as the result of Augustus's rule. This processional frieze challenges comparison with that of the Parthenon, and in the contrast between them lies the difference between the ideals of Greek and Roman. Upon the Parthenon all dignity and majesty is concentrated in the figures of the "Deathless Gods," the people are full of lighthearted gaiety, and not one of them is individually characterised. The true religion of the Romans was their loyalty to the State and its officials; hence upon the Roman frieze the dignity and clearly marked personality of the latter is the first quality which strikes the spectator, and the figure of the worshipped is marked by a merely symbolic grace. Augustus knew how to use every Roman feeling of devotion to early political and religious traditions as yet one further aid to his own greatness. He called himself Tribune of the Plebs for life, and associated himself with the institution of the Flamines as well as with that nature-worship, which, as we have seen, had always had so strong a hold on the devotion of the Roman mind. Where Julius had openly grasped at absolutism and had fallen, Augustus built up his power by diplomacy and succeeded.

DISCUSSION.

The CHAIRMAN said it was only occasionally that the members of the Society had the opportunity and pleasure of hearing a paper read by a lady; and he was sure everyone present would agree with him that the presence of Mrs. Burton-Brown had been very welcome, and that they had listened to her admirable paper with very great appreciation. There must be many members whose professional and business duties prevented them visiting the interesting places of the world; and on looking at the wonderful photographs which had been shown he could not help feeling what a great debt everyone owed to the great improvements that had been made in photography during the last 20 years by means of which the treasures of the world had been brought to their very door; in fact, there were comparatively few places of great interest which were not to a certain extent known, thanks to those good-natured people, like the

authoress, who wandered about the world with their eyes open for any artistic possibilities, with camera ready to be touched, and with the pocket-book handy in which to take down notes. Although great artistic institutions sent their promising students to Rome, it was on the camera that the majority of students must rely if they wished to increase their artistic knowledge by constant reference to the antique. The thoughts of every student turned to Rome, and it was not surprising that it should be so when one looked at the beautiful specimens of architecture and sculpture that were constantly being shown on the well-known screen of the Society. Only the previous day, Mr. Starkie Gardner gave a most interesting lecture at the Society on Bronze, and there again the finest work was Italian; in fact, which ever way they turned, if the papers were in any way connected with art, the screen was bound to have some representation of Roman art upon it. It was not only in art matters, however, but in other subjects that Roman influence predominated. For instance, he noticed in the paper Mrs. Burton-Brown mentioned that in the arena the wild beasts were taken up to the performance by lifts, in the same way that similar performances were conducted at the Hippodrome or the Coliseum at the present day. An open-air hospital had also been mentioned, which made one believe that perhaps the modern cure for diseases of the lungs was not so very modern after all.

Prof. Flinders Petrie, F.R.S., stated he had come to the meeting with the hope of getting a clearer crystallisation of ideas in regard to the discoveries which had been made during recent years in the Forum, and he had been amply rewarded. He would only say how glad all the members were to have the various discoveries so well oriented and put together in order that they might grasp them more clearly and see their meaning more distinctly, thus being better prepared for looking over the ground the next time they passed through Rome.

On the motion of the Chairman, a hearty vote of thanks was accorded to Mrs. Burton-Brown for her interesting paper, which Mrs. Burton-Brown briefly acknowledged, and the meeting terminated.

LARGE IRRIGATION SCHEME FOR THE PUNJAB.

The Government of India has just published the report of the Chief Engineer, Mr. J. Benton, C.I.E., on the Project Estimates of the Upper Jhelum, Upper Chenab, and Lower Bari Doab Canals, the construction of which has been recently authorised. The entire scheme is one of considerable importance and magnitude, involving an expenditure of Rs.7,82,38,925 (approximately, £5,216,000). Of the three canals, the Upper Jhelum Canal is to irrigate portions of the Upper Jech Doab, and convey the surplus water of the Jhelum to the Chenab River, tailing in above the head works of the existing Chenab Canal. The Upper Chenab Canal, is to commence opposite Sialkot, and to draw off as much water as is tailed in by the Upper Jhelum Canal, is to proceed through Gujranwala to the Ravi, irrigating portions of the Upper Rechni Doab. The Lower Bari Doab Canal, is to start from the end of the Upper Chenab Canal and to irrigate the Lower Bari Doab tract. The following Table gives the leading particulars concerning the cold weather supply in the Punjab rivers:—

1. *River Indus.*—Wholly unutilised at present. Surplus cold weather supply in cusecs, 9,434 (minimum). Tracts to be served with cold weather supply—(i.) Sind Sagar Thal. (ii.) Sidhnai Canal. (iii.) Chenab series of canals, Mooltan district.
2. *River Jhelum.*—Lower Jhelum Canal. Balance wasted at present. After setting aside 2,000 cusecs for the Lower Jhelum, the average amount of surplus water throughout the cold weather will be from 5,651 to 7,946 cusecs in dry and ordinary years respectively. Tracts to be served with surplus cold weather supply—(i.) Upper Jech Doab, by proposed Upper Jhelum Canal. (ii.) Upper Rechna Doab, by proposed Upper Chenab Canal. (iii.) Lower Bari Doab, by proposed Lower Bari Doab Canal.
3. *River Chenab.*—All utilised by existing Lower Chenab Canal. Surplus cold weather supply, nil.
4. *River Ravi.*—All utilised by existing Upper Bari Doab and by Sidhnai Canals. Surplus cold weather supply, nil.
5. *River Beas.*—Wholly unutilised. Flows into the Sutlej at Hariki. Surplus cold weather supply in cusecs, 4,000 (minimum).
6. *River Sutlej.*—Wholly utilised at off-take of Sirhind Canal at Rupar. No surplus water, but receives a supply at the confluence of the Beas of 4,000 cusecs. Beas River to be wholly used for Sutlej Valley, riverain tracts, and high land on each side.
7. *River Jumna.*—Wholly utilised by Eastern and Western Jumna Canals. Surplus cold weather supply, nil.

Considerable attention was given during the period of drafting the scheme to the question of a sufficiency of water for irrigation during the cold weather. From observations of the available supply which had been collected during the preceding fourteen years, it was found that in ordinary years, which occur twice in four years, there was a satisfactory surplus. In favourable years (occurring once in four) a larger margin, in dry years a bare margin, while in extraordinarily dry years there would be a deficiency of 11 per cent., an amount which occasionally occurs with existing canals. In this connection the con

version of the Woolar Lake into a great reservoir for the storage of flood water has been mooted. As an additional supply is only required at rare intervals, the consideration of this project is for the present postponed.

The following are the leading particulars concerning the three canals:—

Particulars.	Canal.		
	Upper Jhelum.	Upper Chenab.	Lower Bari Doab.
Length of Main Line (miles)	88	99	43
Length of Branches (miles)	48	113	113
Length of Distributaries (miles)	562	1,092	1,060
Discharge at Head of Main Line (cusecs)	8,500	11,694	6,481
Annual Irrigation (acres)	344,960	648,367	882,528
Annual Gross Revenue, Direct and Indirect (rupees)	18,35,040	32,14,789	45,32,640
Annual Nett Revenue, Direct and Indirect (rupees)	13,60,720	25,66,422	38,70,744

In order to popularise the speedy development of irrigation, Mr. Benton suggests that on all old village lands water should be supplied free for one crop, and at half rates for the next. Such a procedure would hasten the extension of irrigation by facilitating the rapid construction of watercourses through privately-owned lands, a work of much importance, liable to be delayed if great inducements are not offered.

The annual amount of land to be irrigated by these canals is estimated to be 1,875,855 acres, while it is highly probable that this will exceed 2,000,000 acres as the works become fully developed. Several very important reasons are given for the sanctioning of this important project. Among these may be cited several which are also common to all irrigation schemes, and which unhappily represent the state of affairs in many districts where irrigation is impossible. On their completion famines will for ever cease in the Gujrat district, which will be irrigated by the Upper Jhelum Canal; the dense population of the Upper Rechna Doab, to be irrigated by the Upper Chenab Canal, will find their circumstances greatly improved; while the Sharakpur Tahail of the Lahore district will become as prosperous as the Chanab Canal Colonies, and the great unfructuous dry jungle wastes of the Lower Bari Doab, to be irrigated by the Lower Bari Doab Canal, will become one of the richest and most fruitful in the province. In addition, the widespread failure of crops dependent on rainfall in Gujrat, Shahpur, Gujranwala, Lahore, Montgomery, and Mooltan districts, may be expected to practically cease for those portions of these districts which lie within the tracts commanded by the proposed works.

Quite apart from these important humanitarian considerations, the available food produce of the country will be greatly increased, with the result that Government railway receipts, which always benefit by irrigation works, will be greatly increased. Part of the Lower Bari Doab will be available for colonisation, and thus relieve the congestion in certain other districts, and at the same time afford the Government the opportunity of rewarding many of its deserving servants. Industrially, also, great developments are certain to accompany the rise of a prosperous agricultural population. Provision is made in the scheme for the construction of 21 flour mills, containing 270 stones; these are estimated to cost 459,000 rupees, and to yield a nett annual revenue of 1,12,800 rupees. There are two falls, over 30 feet, at the head of the Gujrat branch, and one at the tail 11 feet, which might be used for generating electric energy for transmission elsewhere.

Allowing for the enhanced land revenue which will be obtainable, the three projects will yield a handsome net profit of about Rs.50,00,000 annually after defraying working expenses and meeting interest charges. Apart, however, from the fact that this large scheme offers a financial profit, there will be none who can honestly controvert Mr. Benton's claim that "Government, by executing these works, will make a great, an everlasting, and a praiseworthy advance in its beneficent administration of the country."

GERMAN TRADE.

Mr. Consul-General Schwabach's report on the trade of Germany for 1904 (No. 3.333 Annual Series) affords abundant evidence of the continual expansion of the industrial enterprise of the Empire. Whilst 1904 cannot be described as an exceptionally good year, the condition of German trade and industry was, perhaps, the Consul-General thinks, "better on the whole than that of any other European country." A significant feature of the trade returns is the evidence they afford of the increasing importance of the export trade in machinery and highly-finished iron goods, testifying, as it does, to the unremitting and successful efforts of the German manufacturer to turn out good work at moderate prices, in fact, at lower prices than his competitors. The iron industry, the manufacture of machinery and instruments, and the electrical and chemical industries, at present form the centre of industrial life in Germany. But the great expansion of the iron works necessitated either an enormous increase in the inland demand, or an extension of the export trade if the works were to be fully or even moderately employed. With but a slowly increasing inland demand, and a greatly reduced export trade, the record production of 10,086,000 metric tons of pig iron in 1903 was only just maintained in 1904, and the increase in the output of coke, and also, to a considerable degree, of coal, was smaller than in the two preceding years. Although

the iron and steel works, after completion of the extensions and improvements had been decided upon during the period of great expansion, are capable of a much higher production than they are likely to dispose of for some years to come, the existing iron works are, says the Consul-General, being constantly augmented by the erection of new furnaces and the carrying out of extensive improvements and modernisations. "The policy of expansions for which there is no present need, would seem to indicate great confidence in the possibilities of the industry, possibilities which must be looked for primarily in the export trade, as the inland market, though capable of improvement, is of limited extent. Great attention is paid to reducing the cost of production to a minimum, and manufacturers constantly urge the revision of the goods tariff of the German railways, and the construction of new waterways, in order to lessen the cost of transport. There is also a growing tendency to make each iron and steel works as complete as possible, and practically independent as regards raw materials, and so further concentrate within single works the whole process of production from the smelting of the iron to the finished article."

A Table dealing with the motor-car industry is deserving of attention. The export of motor cars from Germany more than doubled within the last year. The total exports of automobiles in metric tons in 1902 amounted to 527, in 1903 to 588, and in 1904 to 1,309. Of this export 299 tons were exported to the United Kingdom in addition to 235 under the head of "other motor vehicles," 434 to France, 221 to Austria-Hungary, and the rest to various other continental countries. On the other hand Germany imported 846 metric tons of automobiles, and 59 of "other motor vehicles." Of the former almost 75 per cent. were imported from France, and only 19 tons from the United Kingdom; of the latter description 50 tons were imported from the United Kingdom.

In Germany, as elsewhere, the growing demand for industrial labour is thinning the country side. Urban life offers strong inducements to the rural population in the form of higher wages, greater independence, often better housing and treatment, and greater facilities for amusement. The hope that the agricultural labour bureaux, which were considerably extended a few years ago, and systematically connected with labour industrial bureaux, would benefit agriculture by facilitating the exchange of industrial hands has not been fulfilled. "In the year of depression," writes the Consul-General (1901-02), "they no doubt helped to draft a part of the surplus population back to the country, but they proved powerless at the first symptoms of returning industrial activity. Farmers, are, of course, greatly agitated by this state of affairs, and, since they cannot compete on equal terms with the manufacturing industries, they openly advocate the repeal, or at least restriction, of the "Freizugigkeit" or liberty of movement of the agricultural population in order to secure an adequate supply of agricultural labour." The great and ever-increasing dearth of agricultural labourers, particularly in Eastern Germany, makes it necessary to prevent as far as possible the hitherto frequent breach of contracts on their part. With this object a Bill has been laid before the Prussian Diet imposing heavy penalties on agricultural labourers and farm hands for breach of contract. It stipulates, *inter alia*, that whoever engages labourers, farm hands, or servants whom he knows, or might have known to be under contract of service with another employer, shall be liable to a fine of £7 10s., or a corresponding period of imprisonment, and a similar penalty applies to agents, middlemen, or others who induce or persuade farm labourers or servants to quit service n contravention of their agreements, or who assist them to take service elsewhere while still bound by contract.

AUSTRALIAN BUTTER AND CHEESE.*

Although small experimental shipments of Australian butter had been made to London, at intervals, during the last forty years, mostly in air-tight cases, it was only recently that the possibilities of its forming a regular article of export became apparent. Much of the experimental butter was found equal in appearance, flavour and quality to the finest imported from Normandy, from which it could not be distinguished when packed in the French manner. But the comparatively high prices, occasioned by the heavy cost of freight, and the almost total absence of cold storage accommodation on both steam and sailing vessels, proved an almost insuperable obstacle. As these difficulties became surmounted, and it was found possible to place Australian butter on the British market at fairly remunerative prices, the dairy farming industry began to expand rapidly in New South Wales and Victoria, and, subsequently, in Queensland, in which there are extensive areas, embracing a total of several thousand square miles, admirably adapted for dairying purposes. At the end of 1903 the estimated number of dairy cows in the Commonwealth was 1,270,706, of which all, save 115,108, are found in the three States above mentioned. The estimated quantity of milk produced was 343,909,000 gallons, the total value of the milk, butter, and cheese obtained being £5,547,000. The quantity of butter obtained in 1903 was 100,678,000 lbs., Victoria leading the way with 46,686,000 lbs., and New South Wales following with 38,727,000. The cheese production amounted to 13,659,000 lbs., of which Victoria's share was 5,682,000 lbs., and that of New South Wales 4,748,000 lbs. The surplus production available for export, after supplying local requirements, was: butter, 38,675,258 lbs.; and cheese, 1,920,914 lbs.

* Communicated by Mr. John Plummer, Sydney, New South Wales.

In 1904 the production of butter became enormously increased, and it is anticipated that the advance will be maintained in 1905, especially in Queensland, where a considerable portion of the coastal belt possesses a rich soil, with a fairly copious rainfall, while the climatic conditions are apparently favourable to the production of large quantities of milk. Considerable portions of the inland districts are also being utilised for dairy farming purposes, the monthly payments for milk supplies at Warwick alone reaching a total of £1,500. In New South Wales the exports of butter have risen from 284,257 lbs. in 1889, to 7,461,575 lbs. in 1903; in Victoria, from 505,478 lbs. in 1889, to 15,908,342 lbs. in 1903; in Queensland, from 1,064 lbs. in 1893, to 951,501 lbs. in 1903; and in South Australia, from 10,050 lbs. in 1890, to 453,656 lbs. in 1903. In 1900 New South Wales exported 8,477,617 lbs.; Victoria, 26,185,679 lbs.; while in 1894 the South Australian figures were 1,233,539 lbs. These were favourable years. In New South Wales the coastal districts south and north of Sydney are among the finest in existence, the bulk of the milk consumed in the State being obtained from the Illawarra region, where the pasturage is of a most luxuriant character, especially in the country watered by the Shoalhaven River, the rich alluvial flats on either side of the stream being studded with plump, sleek dairy cattle, which any British or other gentleman farmer would be proud of possessing. Neither France nor Denmark can produce butter of a finer quality than that made in this part of the Commonwealth. Victoria is fortunate in the possession of rich natural pastures, which, as in portions of the other States, renders unnecessary much of the artificial feeding indispensable in colder countries. A considerable portion of the butter and cheese production is based on the co-operative system. The dairy farmers supply the creameries and butter factories with milk on certain terms periodically arranged, the payments being in accordance with the quality of the milk. They also participate in the profits obtained from the sale of the butter and cheese. The skim milk is used for feeding pigs. The number of butter and cheese factories in Victoria in 1903 was 207; there were also 281 creameries, the total number of hands employed being 1,319, and the value of the buildings, machinery, plant, &c., £524,448. In New South Wales there were 125 butter factories and 97 creameries, employing 951 hands, the value of the machinery, plant, &c., exclusive of land, buildings, &c., being £182,567. With the opening up of fresh country by means of railway and other means of communication, and the subdivision of extensive areas alienated in bygone years and now required for closer settlement, a further expansion, on a most extensive scale, is inevitable. A gcod dairy farm in experienced and industrious hands is said to be a surer source of competence, if not wealth, than would be the possession of a rich gold mine.

STATISTICS OF THE FEDERATED MALAY STATES.

There was published in the autumn of 1904, at Kwala Lumpur, the capital of the Federated Malay States, a Blue-book entitled "Manual of Statistics Relating to the Federated Malay States." Its compiler, Mr. A. R. Venning, the Federal Secretary of the Federated Malay States, explains in the introduction that "The publication of a Blue-book for the Federated Malay States in the form adopted by the Colonial Office for use in British Colonies has not hitherto been found practicable under existing conditions; but, at the same time, there is ample evidence of a demand for statistics to show the position of these States in respect of such matters as Population, Financial Prosperity, Trade, Customs Duties, Railway Construction, &c." To meet this demand, this Blue-book, printed at the Government printing office, has been prepared. It gives a complete list of all taxes, duties, fees, &c., in connection with mines, forests, harbours, and other sources of wealth, or branches of industry which lend themselves to taxation. Particulars are also given of the revenue and expenditure of Perak, Selangor, Negri, Sembilan and Pahang; since 1875, in the case of the first three, and since 1889 in the case of the State last mentioned. The amount of revenue collected under various heads is recounted, nearly one-half being obtained in the shape of an export duty on tin. The Federated Malay States possesses a Public Works Department, which has done a great deal towards the development of the country. During the past five years 3,731,508 dols. have been expended on the construction of roads, streets, and bridges. As regards the mileage of roads, there have been constructed and maintained 1,079 miles of metalled cart roads, 400 miles of other cart roads, and 683 miles of bridle paths. The capital expenditure on some 340 miles of railway open for traffic amounted, on December 31st last, to 31,060,657 dols.

As regards area and population, the gross area of the four States amounts to 26,380 squaie miles, of which 523,408 acres are alienated under permanent title for agricultural, and 290,002 acres for mining purposes. Forest reserves of a total area of 242,816 acres have been provided. The bulk of the agricultural land is given to rice cultivation, 125,811 acres being under this crop. Cocoanuts are grown on 74,650 acres, tapioca on 39,731 acres. Rubber is cultivated on 24,551 acres, coffee on 22,701, and sugar on 17,729 acres. Some 25 acres have been planted with cotton. The total population at the time of the last census amounted to 678,595 persons, of whom 1,422 were Europeans or Americans, 1,532 were Eurasians, 299,739 Chinese, 312,486 Malays and miscellaneous aboriginal inhabitants of the Malay Archipelago, 58,211 Tamils and other Indians, and 2,582 other races. Of the Chinese population, 6,056 are Straits born, and 27,155, or, practically, 1 in 11, are females.

Import and export trade returns are given, the former in 1903 being slightly under 48,000,000 dols., and the latter slightly over 80,000,000 dols. Of individual items of import, live animals, food, drink, and narcotics account for rather less than two-thirds, or 30,112,685 dols., manufactured articles of 6,933,748 dols., and bullion and specie for 6,362,772 dols. The chief item in the export returns is that of 73,500,000 dols. for raw materials, consisting mainly of tin and tin ore. In connection with this latter, several columns of figures are given of the weight of tin and tin ore exported, but an enumeration of the values is lacking.

This interesting review closes with some meteorological tables, and a note on the chief features of the meteorology of the Federated Malay States by Mr. A. E. Young. It appears that "the climate of the Federated Malay States is very uniform, and can be described in general terms as hot and moist. The annual rainfall, except in places close to the mountain ranges, is about 90 inches. In towns such as Taiping, Tapah, Selama, &c., close to high mountains, upwards of 50 per cent. more is registered, the average of ten years' record at the first-named being 164 inches. There is no well-marked dry season. Generally speaking, July is the driest month, but has seldom anywhere a less rainfall than 3½ inches. The wettest season is from October to December, and there is another wet season of slightly less degree during March and April. Rain rarely falls before 11 a.m., so that six hours of out-door work can generally be depended upon all the year round.

"The average maximum temperature occurring between noon and 3 p.m., is in low country just under 90 deg., and the average minimum occurring just before sunrise is just over 70 deg. The general mean temperature is just about 80 deg. There is very little change in the mean monthly temperature during the year, the average of ten years' readings in Taiping exhibiting a difference of only 3·2 deg. between the mean temperature of May, the hottest, and of December, the coldest, month of the year."

SISAL PRODUCTION IN THE PHILIPPINES.

Maguey or sisal fibre has a variety of uses in nearly all civilised countries of the world. In the United States it is used principally for binder twine, also for ships' ropes and cables and for small cordage. In Mexico and South America it is employed in the manufacture of lines, nets, hammocks and saddle cloths. In European countries it is used for various classes of cordage. The active efforts of cordage manufacturers to obtain suitable material to supply the growing demand for fibre have greatly increased the interest of producers in the development of sisal production in various parts of the world. According to a recent report by the fibre expert of the Philippine Bureau of Agriculture, there is reason to believe that the production of maguey or sisal can be made one of the most important industries of the Philippine Islands. The plant is already widely distributed, having been reported from twenty-two different provinces of the islands, and the output has grown to such an extent that beginning with June, 1904, separate mention of the amount exported is to be made in the monthly trade bulletin issued by the Bureau of Insular Affairs. Most of the fibre at present imported into the United States is produced in Mexico and Central America. There is a good demand for it, the current quotations in the New York markets usually being but about two cents less per pound for sisal than for the Manilla hemp. In the Phillippine Islands there are large areas of land suitable in every way for the cultivation of this crop, and efforts are being made to improve the conditions of plantation management and to encourage the introduction of modern fibre extracting machinery. Maguey was first introduced into the Philippine Islands from Mexico or Central America by the Spaniards. The plant has long been grown in a small way, but it is only in very recent years since there has been an increased demand for the fibre, that its cultivation has become an important industry. From the provinces of Ilocos Norte, Ilocos Sur, and Union, maguey fibre is now exported in large quantities. The plant is found in many other provinces, and in numerous instances the fibre is extracted for local uses. The production of abaca, or Manilla hemp fibre, has been such an important industry in the islands, and its cultivation has received so much attention that the good qualities and true value of maguey have been, to some extent, overlooked. Ilocos Norte and Ilocos Sur are the two important maguey producing provinces of the islands. Nearly all the fibre exported comes from these two provinces, the plant being found in all districts. In the pueblo of Batac, it is estimated that one-fourth of the population is engaged in producing maguey. In Paoay it is stated that there are 750 acres of maguey under cultivation. It is the general custom on plantations to use the rich lowlands for rice and corn, reserving for maguey, sandy knolls, and any waste lands, it being considered that the only requirement for maguey is sufficient room in which to grow. There has been a great increase in the area devoted to the cultivation of maguey in Ilocos Norte during the past few years, owing to the higher price paid for the fibre. The province of Ilocos Sur produces by far the largest amount of maguey fibre of any province in the islands. The plant consists of a heavy short stem which bears an aloe-like cluster, or rosette, of from twenty to forty thick fleshy leaves. These leaves are from three to seven feet long, and from two to four inches wide. They are light green in colour, are covered with a whitish powdery substance, bear sharp lateral teeth and a terminal spine. The leaf is composed of pulpy material interspersed with vascular bundles which furnish the fibre. When the plant

matures, which is in from seven to fifteen years, a central stalk or pole grows to the height of from fifteen to twenty feet. This stalk first bears flowers, and afterwards a large number of small bulbs, which, when mature, fall to the ground. After flowering once the plant dies. The fibre of the maguey, belonging to the class known as structural fibres, it produced by the leaves. I is obtained by separating the pulpy portion of th leaf from the fine filaments, or fibro-vascular bundles which run along this pulp. The fibre, if carefully separated and dried, is quite white and brilliant. It is four or five feet long, is fine and soft, and is more wavy or fluffy than Manila hemp. Another market quality is its great elasticity. It is said that its main faults are its stiffness, shortness, and thinness of wall, of the individual fibres, and a liability to rot. With reference to the relative tensile strength of the two fibres, it is claimed that Manila hemp spun into a single-strand twine, 650 feet to the pound, should show a tensile strength of 85 pounds for the breaking strain of the weakest portion, while sisal running 500 feet to the pound will show a tension of 50 pounds at breaking strain of the weakest part. Almost any tropical or sub-tropical climate appears to be favourable to the growth of maguey. Owing to its long, fleshy leaves, it will not suffer during a prolonged drought, while it also flourishes in the humid climate and during the rainy season of he Philippines. It is stated that in a humid climates a longer and more elastic fibre is produced. The only injury which the plant suffers in the Philippine Islands from climatic conditions is from the strong winds whieh sometimes tear and lacerate the leaves. There are several methods used in the Philippine Islands for extracting the fibre :—(1) The abaca stripping process; (2) the split bamboo stripping process; (3) the piña scraping process; and (4), the maceration and retting process. The methods of extracting by which the fibre is separated from the pulp without the use of water for retting give a product of very superior quality. These methods, however, are slow and laborious, and are not in any general use. The retting process has for its object the dissolution of the gummy, resinous substance which envelopes the filaments. This substance being very adhesive prevents the free separation of the fibres. If the leaf is not sufficiently rolled, the fibres will still adhere to each other, while if the process is carried too far, the product is seriously injured or rendered utterly worthless. Two distinct methods are in use. In one, the leaves are cut, crushed or beaten, gathered in bundles, and allowed to ferment. When fermentation has ceased the bundles are placed in water until the pulpy material has further deteriorated. By this process one-third or more of the product is converted into tow. By the other method, after the leaves are cut and the thorns removed, they are split in four or five pieces and made into bundles, these bundles being immediately placed in the water for retting. Much depends upon the water used for retting; salt water is preferable to fresh. The tide waters of rivers are most generally used. When the retting process i complete the fibre is removed from the water and dried in the sun. This drying ordinarily requires from two or three days, care being taken that the fibre is not exposed to rain or heavy dews during the drying process as these will injure its appearance. After being thoroughly dried a shaking and brushing is necessary to remove whatever extraneous matter may still adhere to the fibre. The finished product is now ready for baling. During whatever process is necessary care is always taken that the fibre is kept dry, and that the different strands and hanks do not become tangled and dirty. The use of fibre-extracting machines is a question which has received much attention, and is a matter of general interest in the Philippine Islands. In the case of abaca no machine has been introduced which has met with any considerable degree of success. With maguey, however, several different machines are in use in Mexico, the West Indies and Hawaii. There appears to be no reason why such machinery should not be in use in the Philippines. The quantity of fibre produced is amply sufficient to justify its introduction. With suitable climate and soil conditions it only requires machinery to make the production of maguey an important industry in these islands. Maguey or sisal fibre has a recognised place as one of the leading commercial fibres of the world. Its production on a large scale has proved to be a profitable industry in Mexico and Central America, where conditions are in no way more favourable than conditions in the Philippines. With the same business-like management of plantations, and the use of fibre-extracting machinery, the industry, according to the Philippine Bureau of Agriculture, is one which should yield reasonable profits and which is worthy of being widely extended in the islands. Maguey plantations constitute a safe and profitable industry, and where abaca will die for want of water, and cotton is destroyed by insect enemies, maguey continues to flourish and to yield good returns.

ALCOHOLIC BEVERAGES.

A very interesting memorandum has recently been presented to Parliament showing the production and consumption of alcoholic beverages in the various countries of Europe, in the United States, and in the principal British colonies. On page 26 there is a statement showing the part played by the revenue derived from these beverages in governmental finance. Nowhere do taxes on them contribute so large a part of the total national revenue as in the United Kingdom, where the proportion is 32 per cent. The United States comes next with 29 per cent.; then come the Dominion of Canada and Holland with 19 per cent., France and Belgium following with 18 per cent. The percentage for Germany is not worked out owing to the revenue from beer being

raised by the States in several portions of the Empire. Passing to particulars, and beginning with beer, the United Kigdom ranks after Germany as the greatest producer. In 1903 the German production was 1,516,944,000 gallons, as against 1,279,367,000 gallons for the United Kingdom. In the 14 years 1890-1903, that is, during the completed years in which the standard gravity remained unchanged, the consumption of beer per head of population in this country was lowest (29·5 gallons) in 1894, from which point it rose yearly until in 1889 it reached 32·6 gallons. Since then it has steadily declined, and in 1903 amounted to 29·7 gallons. The fluctuations correspond fairly closely with the changes in industrial prosperity. The figure last given is higher than that of any country included in the tables except Belgium, where the consumption per head increased from 38·5 gallons in 1889 to 48·2 in 1900. In Germany it has ranged from 23·2 gallons in 1891 to 27·5 gallons in 1899 and 1900. But the figures apply to the whole of Germany. In 1899, when the maximum consumption per head was reached, it amounted to 37·8 gallons in Baden, 42·2 gallons in Wurtemburg, and 54·6 gallons in Bavaria. Among the principal British colonies, Western Australia takes the lead with a consumption per head not far below that of the United Kingdom. In Canada it is about 5 gallons per head, and in Newfoundland insignificant.

More spirits are produced in Germany than in any other country, but Russia produces almost as much. The substances used for distillation vary greatly. In Russia spirits are distilled chiefly from potatoes and rye; in Germany from potatoes; in the United States from maize; in France from beetroots and molasses; in the United Kingdom from malt. The greatest consumption per head is attained in Denmark, where it is more than three times as great as in this country, and the lowest probably in Portugal. Taking 1903, the Tables show that the consumption of spirits per head of population in Denmark was 3·07 gallons of proof spirit, the Australian Commonwealth coming next with 3·01 gallons, then Germany and Hungary with 1·76, Holland with 1·72, Sweden with 1·65, and France with 1·56. The United Kingdom had only 0·99 in 1903. In the United States the consumption per head was greater than in this country in 1889-93, but less in 1894-99. In 1900 to 1902 it was again greater, having increased whilst the consumption in the United Kingdom diminished. The consumption of spirits, as of beer, has followed nearly the same course, namely that of of general industrial prosperity.

Just as Bavaria heads the list for consumption of beer, and Denmark of spirits, so France produces and drinks the most wine. Practically no wine is produced in the United Kingdom, and not very much in the Empire, the Cape of Good Hope and the Commonwealth producing between them 11,741,000 gallons in 1903, and the rest of the Empire nothing worth speaking about. During the period when the French vineyards were ravaged by the phylloxera, Italy had, in certain years, a greater output, but since 1899, when there was a practical failure of the crop in both countries, the phylloxera has, to a large extent, been stamped out in France, and in many districts the vineyards have been replanted with hardy American vine roots, on which the more delicate French vines have been grafted. In 1898, and again in 1902, the Italian output was greater than the French, but in 1903 the French was 779,000,000 gallons as against 772,000,000 gallons in Italy. The consumption of wine within the British Empire is relatively small. It is the highest in the Cape, where it reaches two or three gallons per head per annum, though exact figures are wanting for recent years. In the United Kingdom the average of the last five years is only 0·37 gallons per head, and it shows no tendency to increase—rather the contrary. The average consumption per head of population in France, taking the five years 1899–1903, was 23·0 gallons, in Italy 18·2, in Spain 19·4, in Portugal 17·0, in Switzerland 15·2, in Bulgaria 15·0; then comes Roumania dropping to 7·08. Austria-Hungary to 3·1, and Germany to 1·4. The consumption per head of the United Kingdom is almost the same as that of Holland and the United States, and, as in Holland, is entirely derived from imports, whilst the greater part of the small consumption of the United States is of home production. Rather more than one-third of the wine intended for consumption in the United Kingdom is derived from France, about a quarter from Spain, and nearly a quarter from Portugal.

EDUCATION FOR THE CONSULAR SERVICE IN AUSTRIA.

An institution, entitled the Vienna Consular Academy, has been founded in that city for the sole purpose of educating young men for the Consular Service of Austria-Hungary. The pupils receive the same general instruction, the exception being in languages which are divided into Oriental and Occidental departments. Pupils who desire to become consuls in the Near East are placed in the Oriental department, where they receive a thorough training in the Turkish language principally, and in the Arabian and Persian tongues secondarily. Instruction has been given in the Chinese language also during the last two years. According to the American Consul at Eibenstock, the conditions of admission are as follows:—(*a*) Austrian or Hungarian citizenship; (*b*) completion of the prescribed course of study in an Austrian or Hungarian gymnasium; (*c*) knowledge of the French and German languages; (*d*) candidates coming from Hungary must have a good knowledge of the Hungarian language; (*e*) knowledge of any other language by the candidates should be noted in his application. The entrance examinations cover the following subjects:—Oral

examination—(1) General history, from the treaty of Westphalia to the Congress of Berlin in 1878, with special attention to the history of Austria-Hungary; (2) the French language; (3) for Hungarian subjects, the Hungarian language. Written examination—(1) A thesis in the German language upon some given subject; (2) a translation exercise from German into French; (3) the same from French into German. The decision as to candidates to be admitted rests with the Austro-Hungarian Foreign Office. Upon entrance, the pupil is placed in the department best suited to the needs of the service and his inclinations. The course of study covers a period of five years. The subjects taught are as follows:—Political economy, commercial politics, science of finance, materials of commerce, commercial geography, elements of jurisprudence, constitutional law, international law, history of diplomacy, military geography, French, English, Italian, Hungarian, Turkish, Arabian, Persian, German, Russian, and Chinese. Thorough training is also given in gymnastics, dancing, fencing, riding, and swimming. The Government has provided for twenty-five State grants, which permit as many students to attend the Academy at Government expense for a period of five years. Ten of these grants amount to £140 each, and fifteen to £110 each per annum. It is possible for a student in the Oriental department who enjoys a grant of £110, to be advanced to £140 at the beginning of the second school year. This is also possible at the beginning of the fourth year for those pupils who take up the study of the Chinese language during the last two years. Students who complete the five-year course of study may be appointed at once to the active service as consular attachés. Inasmuch as they are greatly favoured by the Foreign Office, their appointment to minor posts in the service is practically a certainty. That the academy is accomplishing the mission for which it was founded is evidenced by the fact that only a few months ago a new building was set apart for its special use.

THE SWEDISH MATCH INDUSTRY.

Match-making is one of the most important among Swedish industries. Between 1830 and 1840, Dr. J. S. Bagge, Professor at the Technical High School in Stockholm, made great efforts to obtain light by means of friction matches. Though the importance of ordinary phosphorus in the production of matches of this kind was tolerably evident, and had actually been pointed out by Berzelius, its use was purposely avoided, until it was discovered that really practical matches could not be obtained without phosphorus in their heads, and Professor Bagge himself drew up directions for their manufacture. Phosphorus matches have been manufactured wholesale in Sweden since 1843. The celebrated match factory in Jönköping was founded by Johan Edward Lundström in 1844. At first sulphorised phosphorus matches were almost the only kind made there. In the same year, 1844, however, G. E. Pasch, Professor at the Caroline Medical Institute at Stockholm, made the discovery that a rubbing surface containing amorphous phosphorus, called by Pasch, phosphor oxide, could be used for matches with heads containing no phosphorus. His invention was patented on October 30th, 1844—a date of importance as proving the priority of Pasch's invention against claims on behalf of a German inventor. The manufacture of matches according to the new patent at once began. According to a report by an official of the Swedish Central Bureau of Statistics, the method employed by Pasch for producing the phosphor oxide was not, however, a very practical one, and it was not until a cheaper method had been discovered in England, in 1851, that his invention was put to practical uses. In this also priority belongs to Sweden, for in 1852 the Jönköping Match Factory commenced to manufacture those "safety matches" which, at the International Exhibition, held in Paris in 1855, were pronounced the best of their kind. The matches turned out by the firm have since attained a world-wide celebrity, and there can be few commodities which have been so often imitated in all parts of the world, both as regards labels and general appearance, as the "Jönköpings Säkerhetständstickors" (safety matches). In the progress of the match industry it has been found necessary to make great use of labour-saving machines, and many machines had already been brought into use before 1870, more especially such as are calculated to simplify the arranging of the splints ready shaped in frames previous to their dipping in the igniting composition to form the heads. A. Lagerman, by his so-called "complete machine," contributed greatly towards reducing the manual labour in match manufacture to a minimum. The match material, which is first cut by other machinery, is fed into the complete machine at one end, to emerge at the other ready-made and packed in boxes, without the intervention of a single workman during the process. One of these machines turns out at least 40,000 boxes in the space of eleven hours. The first machine of this description started working in 1892 in the old Jönköping match factory. A large number of other match factories have sprung up by degrees, but many of them were very soon obliged to cease by reason of the severe competition. Though the old phosphorus matches were driven out of favour by the safety matches, they still continued to be made, but since July 1st, 1901, the sale of them in Sweden has been prohibited, on account of the danger connected with the yellow phosphorus contained in their heads. They possess, however, one advantage over the safety matches which cannot be denied them, and that is said to be the possibility of striking them on almost anything. Continued experiments and the offering of prizes have now resulted in the manufacture of matches which may serve as a substitute for the old phosphorus matches

without containing the yellow poisonous phosphorus, instead of which is used in the Jönköping factory, sesquisulphide of phosphorus. Most of the chemicals required in match-making, such as phosphorus, antimony. sulphur. paraffine, &c., must be imported; chlorate of potash, on the other hand, can now be obtained in Sweden. The sort of wood in greatest and almost exclusive request for matches is aspen; it is easy to cut up, and is sufficiently porous to admit of impregnation with sulphur or paraffine. The home supply of aspen wood of a sufficiently good quality for use in match-making, has now been so reduced that a considerable amount has to be imported from Finland and especially from Russia. The most serious obstacle to the progress of the match industry in Sweden, or even to its continuance in its present proportions, consists not so much in foreign competition as in the excessively high protective duties imposed by other countries to benefit their own manufactures—duties often so high as to preclude all importation — and also the State monopoly on the manufacture of matches established by several countries, *e.g.*, France, Spain, and Greece. The largest match factories in Sweden at present are the Vulcan Factory at Tidaholm, and the Old Factory and the West Factory at Jönköping. At some factories, the headless splints for matches are made for sale. This branch of the industry was estimated at £15,000 in 1900. Swedish matches are exported chiefly to Hamburg and London, for distribution to all parts of the world. In order to avoid competition between home manufacturers, and at the same time to facilitate the trade with foreign countries, the most important Swedish match factories have of late formed a joint stock company, of which the Vulcan Factory and the two factories in Jönköping are the largest shareholders. The total value of matches of Swedish manufacture exported from the country amounted in 1902 to £432,000, and in 1903 to £466,000.

THE PITCAIRN ISLANDERS.

In February of last year the High Commissioner of the Western Pacific instructed Mr. R. T. Simons to proceed to Pitcairn Island in order to inquire into its general state of affairs. Mr. Simons reported on June 25, 1904, and his report has just been published (Cd. 2397). It is rather melancholy reading. The islanders increase in numbers very slowly. In 1878 they did not exceed 90. In 1901 they were returned at 126. Mr. Simons puts them at 141, 68 males and 73 females. "The narrow-mindedness and seeming lack of intelligence noticeable in many of the Pitcairn people," says Mr. Simons, "are more due to ignorance, I think, than to any mental infirmity, and there are now on the island about 40 males and 30 females, ranging from one to seventeen years of age, in need of education and attention." Some years ago the islanders embraced the faith of the Seventh Day Adventists, a religious sect having its origin and headquarters in the United States, and the people contribute 10 per cent. of their produce, and of any moneys they may receive, as a tithe to the church. The produce so contributed is sold, and the proceeds, together with other cash collections, are forwarded to the Foreign Mission Board of the Adventists in America. The only market available for the islanders is Tahiti, and the only communication kept up with it is by means of a cutter, a small vessel of 14 tons, which plies more or less regularly between Pitcairn and Mangareva, where communication with Tahiti and elsewhere may be obtained at intervals of about three months; but there is no anchorage except occasionally in very calm weather. The voyage between Pitcairn Island and Mangareva is often long and boisterous, and no docking facilities are to be had at either place. Some years ago, before they adopted the Adventist faith, the islanders possessed many pigs. To-day there are none in the island. Coffee grows luxuriantly, and is of good quality. Once the islanders have pigs and coffee for export it would be an easy matter, Mr. Simons thinks, to arrange for direct communication between Tahiti and Pitcairn Island, and from the revenues to be derived from these pursuits the islanders should in time be able to procure machinery and appliances adapted to the manufacture of arrowroot, which is of excellent quality at Pitcairn, and worth commercially about £12 per ton.

Mr. Simons says the islanders are "a hard-working people, more or less healthy, exhibiting certain vicious tendencies, which education has been unable to eradicate." They have adopted an extraordinary *patois* (derived from the language of the Tahitian women who accompanied the mutineers of the *Bounty* to Pitcairn Island), which is employed in conversation among themselves, although "most of the adults can speak the English language fairly well." As to the morals of the islanders, Mr. Simons can say little in their favour. They use no intoxicants, but illegitimacy, petty thefts, brawls, and bad language are common, and "it was disquieting to learn that the laws and regulations dealing with those (and other) offences had seldom been enforced." The Government was formerly conducted by a magistrate, assisted by a council of two persons, but "owing to lack of strength and firmness on the part of Government officers," the people became dissatisfied, and in October, 1892, Captain Rooke, of H.M.S. *Champion*, suggested a change. On his recommendation, a president, vice-president, and a judge, and seven members of Parliament, charged "with power to legislate, to plan for the public good, to execute the decisions of the Court, and to see that public demands are speedily attended to," were elected by the islanders in the belief that "a larger number of officers will tend to make a stronger Government, and that plans for the public welfare will be executed with greater success." For some time this method of

administration worked fairly well, but within the last two or three years there has been inquietude. "During my visit," says Mr. Simons, "to the island, I perceived that the functions of the members of Parliament had become merged in those of the president; that the judges, annually elected, were often times incompetent to deal with the matters brought before them, and frequently incapable of enforcing their decisions; that jealousies among the officials had become rife; and that, in view of the general laxity observable, a radical change was necessary." A new system of government was inaugurated by Mr. Simons, and it is to be hoped that it will work better than the old one. The opening up of a system of frequent communication with Tahiti, and a better system of education, would seem to be indispensable if the Pitcairn people are to enjoy anything like prosperity on their very inhospitable island.

TRADE OF MEXICO.

Owing to the troublous times through which it had to pass during the greater part of last century, Mexico is only now beginning to come before the public as a possible country for investments, and there is no good reason why the United Kingdom should not take advantage of this prosperity. In the early part of last century the whole of the commerce of Mexico was practically controlled by British merchants and bankers, and even as late as the early seventies the advance of any undertaking was in a great measure due to British enterprise. But since the construction of the railways in 1875-88 the supremacy in all enterprises has passed into American hands, and there it is likely to remain. But British trade might have a larger share of Mexican orders if only its representatives were abreast of the times. With the development of the country, writes Mr. Bioruland, Clerk to His Majesty's Legation, in his report received at the Foreign Office on March 10 last (No. 3332, Annual Series), the opening up of new districts, both agricultural and mining, the building of the port works and other public works, the construction of railways, the sanitation of many of the large towns of the Republic, the starting of new industries, &c., an ample field is open for all kinds of articles which in former years were never even thought of for this market. Electricity, too, a power which, under the present conditions, seems destined to take the place of steam and water, supplies motive power in districts which last century were still considered to be too far from any centre to be of any importance either for commercial or industrial purposes. This furnishes a sufficient proof that commerce in general is in a more flourishing condition than formerly, and foreign capital has found its way into the country in almost every branch of industry. The Americans have taken advantage of this in a very great measure, and American enterprises are found in almost every State of the Republic, and many places are very prosperous. The Germans also are rapidly increasing their commercial interests in the country, many of the large breweries being controlled by German capitalists, and the hardware trade, both wholesale and retail, is in their hands; but the iron smelters and refineries are not German companies. Agricultural companies have been formed in many of the large cities of the United States for operation in Mexico, as also mining companies, but British influence is felt in very small measure as compared with the former.

The trade of Mexico shows considerable increase in the last six years, for which the returns are available, as will be seen by the following figures:—

Year.	Rate of Exchange.	Value of—	
		Imports.	Exports.
	s. d.	£	£
1897	1 11⅛	7,841,143	12,875,590
1900	2 0	13,094,480	16,881,554
1903	1 8¾	18,220,403	18,587,643

The excess of exports in the year 1897 was greater than in any subsequent year, yet the imports of the year were only about half what they were in 1903. The exports, though showing a steady increase, have not increased so rapidly in proportion as the imports. Turning to the percentage of the import trade of coal of the principal countries during the same period we have the following:—

Country.	Percentage.		
	1897.	1900.	1903.
United Kingdom	19	17	14½
United States	49	51½	53½
France	13	10¼	8¾
Germany	10	11½	12½

As usual, Germany is making headway, but the United States, from their geographical position, must control the largest share of Mexico's foreign trade. Mr. Bioruland makes what would appear to be very sensible suggestions for the quickening of British trade with Mexico. He points out that a careful examination of the country and people by competent persons is essential for ascertaining the wants and requirements of the country and its inhabitants, and though commercial travellers make periodical visits to Mexico they, as a general rule, only inquire into the special branches of commerce in which they are interested, and while they often receive sufficient orders to defray the cost of the going, the country in general does not reap any

advantage from merchandise put on the market in this manner. The business circulars just out continue to be for the most part unsuitable. If they were printed correctly, and in the language of the country, and were to contain the necessary information as to signs and weights, &c., much needlesss correspondence might be saved, and the importers would then be in a much better position to judge whether the goods fulfilled the requirements of the market. Then again English weights and measures always prove a difficulty to foreigners accustomed to the metric system. This question of weights and measures is one of great importance to countries like Mexico, where the import duties are collected on the standard of weight, and where all operations are conducted on the same basis. In many of the American catalogues, Mr. Bioruland says, the prices and discounts are also given, so that the actual cost of an article can be calculated before it is ordered.

THE ALASKAN SALMON FISHERIES.

During the past year there has been a marked decrease in the salmon pack of Alaska. In 1902 the season's catch was 2,631,320 cases, in 1903, 2,631,782, and in 1904 it was estimated at not exceeding 1,935,000 cases, a falling off in two years of 696,320 cases. Throughout the entire world there has been a large reduction of the pack of salmon, which approximately is only 2,810,000 cases for 1904, against 4,317,000 cases for 1902, a loss of 1,507,000 cases. This is an estimate which has been made by the United States Department of Commerce and Labour, and does not profess to be exact, as the detailed statistical reports are not yet all available. Notwithstanding this decrease in the volume of the pack, there has been a marked increase in its aggregate market value, the receipts for 1903 having been about 30 per cent. more than those of the preceding year, and from present indications it would appear that a further increase will be apparent in the complete 1904 figures. The steady decrease in the salmon pack of Alaska is due to constantly enlarging operations of the packers beyond the natural resources of the streams, and to unfavourable conditions under which the propagation of salmon is carried on. The regulations promulgated by the United States Departmeut of Commerce under the law require that persons engaged in taking salmon shall maintain suitable artificial propagating plants or hatcheries, and shall produce yearly and plant in the natural spawning waters of each fishery so operated, red salmon fry in such numbers as shall be equal to at least ten times the number of salmon of all varieties taken from the said fishery during the preceding year. Despite the safeguards which have been thus thrown about the salmon industry by the law and the regulations, and by the personal inspection given by the agents of the Government, the supply of fish, as has been noted, is steadily decreasing. It has been found impracticable to enforce adequate artificial propagation by private persons.

CORRESPONDENCE.

BRITISH WOODLANDS.

Sir George King writes:—I have just had an opportunity of reading Sir Herbert Maxwell's admirable paper on "British Woodlands" in the *Journal* of your Society.

As an old Indian forester I rejoice to see that the subject of British forestry is not allowed to lie dormant, and that the Society of Arts, which has for so many years done its utmost to stimulate this art, is still ready to encourage anyone who shows a real interest in a matter of such vital importance to Great Britain. Would that the Government were equally ready!

The report of the Select Committee of the House of Commons, which sat during the years 1885 to 1887, produced no appreciable result, and the report of the later Commission of 1902 seems, so far as I can ascertain, to have fallen exceeding flat. Beyond the establishment of a small school for lads of the gardener or woodman class under Mr. Hansen in the Forest of Dean, most of the recommendations of the Commission have, so far as I know, been neglected. Sir Herbert Maxwell's paper, backed as it is by Mr. Munro Fergusson, may, it is to be hoped, receive attention in Parliament. The discussion on this paper at the meeting at which it was read recalls to memory a valuable and suggestive paper read before the Society so far back as December, 1894, by that veteran Indian forester, General Michael, C.S.I., who has aptly been called "the Father of Practical Indian Forestry," and to whose initial success in the Madras Presidency, India may be said mainly to owe its present Forest Department. I have the General's paper here, and perhaps I may be allowed to quote from it two very important and inexpensive suggestions which the Commission of 1902 appear to have approved. These are, first, that encouragement and facilities should be given for the education of the class of man most urgently required for the successful working of forests in Britain, viz., a workman who would be content with a salary such as the average British landowner can afford to pay—say, from £60 to £100 a year, and who would not be above working with his own hands. Second, that the Board of Agriculture should maintain a small staff of trained officers, capable of giving sound practical advice about the present and future management of plantations, the services of these men being placed, free of cost, at the disposal of anyone desirous of planting waste land, or of improving already existing

woods. General Michael truly remarks that there must be a number of landowners, large and small, in Great Britain and Ireland, who can point to some acres of land on their properties which, by reason of their being next to worthless for cultivation or grazing, bring in only a shilling or two per acre per annum. Proprietors of such lands would doubtless be glad if they could see their way to render them more valuable for their children or grand-children, but they do not know exactly how to set about doing so. They have vague fears as to the trouble and expense which such improvements might involve, and these fears too often deter them from doing anything. It is here that State aid might advantageously come in; for confidence would probably be established by a personal interview on the spot with a member of such an advisory staff deputed by the Board of Agriculture, who could make suggestions as to details, and who could give a rough estimate of cost. Many a doubting landowner, General Michael says, would probably be both astonished and encouraged by discovering how small an outlay need be incurred in converting an odd and hitherto unprofitable corner of a property into a timber plantation. General Michael, in the paper just referred to, shows how, in many cases, only about £7 per acre would be required. I venture strongly to recommend to anybody interested in British forestry, a perusal of General Michael's paper on "Forestry and Forest Education," printed in the Society's *Journal* for 21st December, 1894. After that paper was read an interesting discussion followed in which Sir Clements Markham, Sir George Birdwood, and Sir Joseph Fayrer took part, and many of their remarks form excellent and instructive reading.

San Remo, Italy.

OBITUARY.

Sir JOHN BARRAN, Bart.—Sir John Barran, who died after a short illness on the 3rd inst., at his residence in London, was a member of the Society of Arts of considerable standing, having been elected in 1877. He was born in 1821, the son of Mr. John Barran, gunmaker, of Wandsworth. Early in life he settled at Leeds, where he founded a large clothing business, and became a prominent citizen. He was mayor of Leeds in 1870 and 1871, and in 1876 he became M.P. for the borough. He lost his seat in 1885, but was returned in the following year for the Ottley Division of West Riding, which he represented until 1895, when he was created a baronet. Sir John Barran was for many years a governor of the Yorkshire College, and he took the greatest interest in the founding of the University of Leeds.

GENERAL NOTES.

OPTICAL CONVENTION, 1905.—As already announced, an Optical Convention will be held at the Northampton Institute, Clerkenwell, E.C., from May 31st to June 3rd, inclusive.. An Opening Address will be given by the President, Dr. R. T. Glazebrook, M.A., F.R.S., on the evening of May 30th. The programme of the Convention includes papers and discussions on optical subjects, an exhibition of optical and scientific instruments, with demonstrations of instruments of special interest, and evening lectures and social gatherings. The mornings will be devoted to the papers and discussions, and many important papers are promised. These will be collected and published in a volume to be issued by the Convention; this volume will be obtainable by members at a reduced rate. Demonstrations of novel and important instruments will be given in the technical laboratories of the Northampton Institute during the afternoons. The Exhibition of Optical and Scientific Instruments will appeal to all users of optical and allied instruments, such as microscopes, binoculars, photographic cameras, projection lanterns, &c. It will be open daily from 12 to 10 p.m. during the Convention, and members will have free admission to it at any time between the hours mentioned. The catalogue, an illustrated volume of some 300 pages, descriptive of British optical and scientific instruments, will be issued to members at a reduced rate. Arrangements for the evenings are being made, and will include lectures and a conversazione. A lecture is promised by Professor Silvanus P. Thompson, D.Sc., F.R.S., President of the Optical Society. This will probably be given on the evening of Thursday, June 1st. On the afternoon of Saturday, June 3rd, an opportunity will be given for the inspection of the National Physical Laboratory, Teddington, at the invitation of Dr. R. T. Glazebrook, M.A., F.R.S., the President of the Convention.

ALIEN IMMIGRATION.—The return just issued "of the number of aliens that arrived from the Continent at ports in the United Kingdom in each month for the year 1905," shows an increase in the immigration as compared with 1904. The return is brought down to the 31st March, and if that month of the two years is taken the gross numbers are 20,115 for March, 1905, as compared with 16,888 for the same month of 1904. If deduction is made of the aliens known to be *en route* to other countries, the figures are 8,118 for March, 1905, and 5,899 for March, 1904. Deducting again the number of sailors included with the aliens, not described in the alien lists as *en route* to places out of the United Kingdom, the figures are further reduced to 6,828 for March, 1905, and 4,857 for March, 1904. Taking the gross figures for the three months they are 42,287 for the period ended March 31, 1905, and 34,437 for the

similar period of 1904. Deducting aliens *en route* the figures are 21,685 and 15,773 respectively, and again deducting sailors the figures are further reduced to 18,398 and 12,782 respectively. A note to the return points out that the figures as to aliens *en route* are incomplete inasmuch as "particulars on this point are not required by law to be furnished."

THE REVENUE FROM WINE.—The Chancellor of the Exehequer in his Budget statement complained that "the wine duties have for many years been a falling source of revenue." But a Board of Trade paper issued last month (Alcoholic Beverages, 1903), shows that the Customs Revenue—and of course there is no Inland Revenue—from wine has steadily increased. Thus the receipts in the years named were as below, 1902 being the latest given in the return:—

1892.		1897.		1902.
£		£		£
1,268,000	..	1,325,000	..	1,524,000

If Mr. Austen Chamberlain had said that the consumption per head had fallen he would have been right, although the fall has been very slight. The consumption was 0·38 in 1889, and the average of the last five years was 0·37. It is practically stationary. Mr. Austen Chamberlain lamented the decline in the import of wines from British possessions. But the production has not diminished. In Australia it has nearly doubled in ten years. In 1893 the total production was 3,567,025 gallons, in 1903 it had risen to 6,159,169 gallons. In 1893 the production of the Cape of Good Hope was 6,145,344 gallons, but that was an exceptional year; in 1903 it was 5,332,349 gallons. Not much wine is produced in other colonies. Ontario is credited with 500,000 gallons in 1900, but there are no returns for other years, and returns are also lacking for Cyprus and New Zealand.

WINDMILLS FOR SOUTH AFRICA.—German manufacturers appear to be devoting special attention at the present time to the demand which has sprung up for windmills in South Africa. Austrian manufacturers are also doing all in their power to get control of the South African market, and the American representative at Chemnitz says in a recent report to his Government that both the Germans and Austrians are making disastrous inroads into the market in the lines mentioned. This demand for windmills has arisen owing to the continued dry seasons in South Africa. The sinking of wells has become a necessity, and even the Government boring machines have been called into use to supply cattle with the necessary quantity of water to sustain life. Two kinds of motors are saleable, a light one for pumping water for cattle, and a heavier one to pump for irrigation purposes. Of the first kind there is a great variety on the market at Cape Town. The main points considered in purchasing such motors are lightness combined with great capacity, facility of removal from one place to another, and ability to be set in motion by the lightest breeze. Windmills answering these conditions are at the present time very scarce, and it would be well for British manufacturers to give strict attention to this market if they wish to retain it. Care should be given to the questions of packing and shipment. Duplicate parts should be available, so that broken machinery can be repaired at short notice. This is a point to which German manufacturers devote special attention.

REVENUE (COLLECTION OF TAXES).—The returns showing for each of the three kingdoms (1) the amount charged for House Tax, Land Tax, and Inhabited House Duty for the financial years 1903, 1904, 1905, and (2) the amounts and per-centage of same collected in each country by 31st day of January and 28th of February respectively in each of these years, hardly supports the general opinion that payments this year have been very much quickened by the pressure of the authorities. Taking England, the return shows that at the end of January, 1903, the per-centage collected was 32·4 as against 29·5 in 1904, and 35·0 in 1905; and at the end of February the per-centage stood at 56·0, 55·5, and 62·6 respectively. It is explained in a note that the year 1903-4 was a year of re-valuation of property assessed under Schedules A and B in England and Wales outside the metropolis. Re-valuations always cause some delay in the assessments under the schedules, and, as a result, the collection in the months of January and February, 1904, was retarded. Comparing then 1903 with 1905, and taking the end of February, the per-centages are 56·0 and 62·6 respectively. It is noticeable that in Scotland 95·8 per cent. had been collected by the end of February, 1905, and in Ireland only 50·09.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

MAY 10.—The Native Races of the Unknown Heart of Central Africa." By VISCOUNT MOUNTMORRES. J. CATHCART WASON, M.P., will preside.

MAY 17.—"The Use of Wood Pulp for Paper Making." By S. CHARLES PHILLIPS, M.S.C.I.

MAY 24.—"Modern Lightning Conductors." By KILLINGWORTH HEDGES, M.Inst.C.E., Hon. Sec to the Lightning Research Committee.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

MAY 11.—"The Manufactures of Greater Britain. —III. India." By HENRY JOHN TOZER, M.A. HIS HIGHNESS THE MAHARAJA GAEKWAR OF BARODA, G.C.S.I., will preside.

MAY 18.—"Plague in India." By CHARLES CREIGHTON, M.D. SIR DENNIS FITZPATRICK, K.C.S.I., will preside.

COLONIAL SECTION.

Tuesday afternoons at 4.30 o'clock:—

MAY 23.—"The Cape to Cairo Railway." By SIR CHARLES H. T. METCALFE, Bart., M.Inst.C.E. The DUKE of MARLBOROUGH will preside.

APPLIED ART SECTION.

Tuesdays, at 4.30 or 8 o'clock:—

MAY 16, 4.30 p.m.—"Excavation of the Oldest Temple at Thebes." By H. R. H. HALL, M.A.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

ALAN S. COLE, C.B., "Some Aspects of Ancient and Modern Embroidery." Two Lectures.

LECTURE II.—MAY 8.—Embroidery in England, 12th and 13th centuries—MS. illumination, painting and embroidery as secular arts in 13th and 14th centuries—Influence of work in one art craft (the Goldsmiths') on that in another (Embroiderers')—Types of ecclesiastical English embroidery 13th, 14th, and 15th centuries, compared with contemporary illuminations in MSS. — Designs for English embroidery gradually affected by developments in ornamental weaving abroad—Symmetrical and floral patterns taking the place of designs with figure subjects having an epical or story-telling interest—English secular embroidery of the 16th and 17th centuries — The "conceits" in embroidery of the Elizabethan and Stuart periods—Embroidery in costume in 16th, 17th, and 18th centuries—Aspects of modern English embroidery—the designs for it: different phases of its practice, for ordinary trading purposes, for more limited purposes, and for special occasions in connection with technical instruction—Embroidery.

HENRY WILLOCK RAVENSHAW, Assoc. M.Inst.C.E., Mem.Fed.Inst.Min.Eng., "The Uses of Electricity in Mines." Two Lectures.

LECTURE I.—MAY 15.—*Application of Electricity and Character of Load.* — Winding—Haulage—Pumping—Coal cutting—Other uses underground—Surface requirements—Generating stations—Cables and distribution — Lighting — Signals — Telephones—Shot firing.

LECTURE II.—MAY 22.—Alternating and direct currents — Precautions — Enclosed motors — Home Office rules—Costs—Typical and historical plants described.

The lectures will be illustrated by lantern slides.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MAY 8...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Mr. Alan S. Cole, "Some Aspects of Ancient and Modern Embroidery." (Lecture II.)

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Sanitary Institute, Margaret-street, W., 5 p.m. Dr. Louis C. Parkes and Mr. W. Rolfe, "Housing in Mansions let as Flats."

Geographical, University of London, Burlington-gardens, W., 8½ p.m. Lt.-Col. C. Delmé-Radcliffe, "The Nile Provinces and Western Uganda."

Camera Club, Charing-cross-road, W.C., 8½ p.m. Mr. Horace Fulton, "The Photo-Lino Process."

Medical, 11, Chandos-street, W., 8 p.m. Annual Meeting.

TUESDAY, MAY 9...Hellenic (in the Rooms of the Society of Antiquaries, Burlington-house, W.), 5 p.m.

Asiatic, 22, Albemarle-street, W., 3 p.m. Annual Meeting.

Royal Institution, Albemarle-street, W., 5 p.m. Prof. L. C. Miall, "The Study of Extinct Animals." (Lecture III.)

United Service Institution, Whitehall, S.W., 3 p.m. Commander the Lord Ellenborough, "The Possibility of our Fleets and Harbours being Surprised."

Medical and Chirurgical, 20, Hanover-square, W., 8½ p.m.

Photographic, 66, Russell-square, W.C., 8 p.m. Mr. E. P. Butler, "Three-Colour Photography—with Examples."

Anthropological, 3, Hanover-square, W., 8½ p.m.

Colonial Inst., Whitehall Rooms, Whitehall-place, S.W., 8½ p.m. The Earl of Ranfurly, "New Zealand and its Dependencies."

Horticultural, Drill-hall, James-street, Victoria-street, S.W., 3 p.m. 1. Mr. N. Hayashi, "Japanese Horticulture." 2. Mr. R. Farrer, "Japanese Plants and Gardens."

WEDNESDAY, MAY 10...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. The Viscount Mountmorres, "The Native Races of the Unknown Heart of Central Africa."

Biblical Archæology, 37, Great Russell-street, W.C., 4½ p.m.

Geological, Burlington-house, W., 8 p.m.

Royal Literary Fund, 7, Adelphi-terrace, W.C., 3 p.m.

THURSDAY, MAY 11...SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Indian Section.) Mr. Henry J. Tozer, M.A., "The Manufactures of Greater Britain. III.—India."

Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Royal Institution, Albemarle-street, W., 5 p.m. Prof. Sir James Dewar, "Flame." (Lecture II.)

Electrical Engineers (in the ROOMS OF THE SOCIETY OF ARTS), John-street, Adelphi, W.C., 8 p.m. Mr. H. Laws Webb, "Telephone Traffic."

Camera Club, Charing-cross-road, W.C., 8½ p.m. Colonel David Bruce, "In the Fly Country" (Central South Africa).

FRIDAY, MAY 12...Royal Institution, Albemarle-street, W., 9 p.m. Prof. Ernest Fox Nichols, "The Pressure due to Radiation."

Astronomical, Burlington-house, W., 8 p.m.

Clinical, 20, Hanover-square, W., 8½ p.m.

Physical, Chemical Society's Rooms, Burlington-house, W., 5 p.m.

SATURDAY, MAY 13...Royal Institution, Albemarle-street, W, 3 p.m. Prof. Marshall Ward, "Moulds and Mouldiness." (Lecture II.)

Journal of the Society of Arts.

No. 2,738. VOL. LIII.

FRIDAY, MAY 12, 1905.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

NOTICES.

NEXT WEEK.

MONDAY, MAY 15, 8 p.m. (Cantor Lecture.) H. W. RAVENSHAW, "The Uses of Electricity in Mines." (Lecture I.)

TUESDAY, MAY 16, 8 p.m. (Applied Art Section.) H. R. HALL, "Excavation of the Oldest Temple at Thebes."

WEDNESDAY, MAY 17, 8 p.m. (Ordinary Meeting.) S. CHARLES PHILLIPS, "The Use of Wood Pulp for Paper Making."

THURSDAY, MAY 18, 4.30 p.m. (Indian Section.) CHARLES CREIGHTON, M.D., "Plague in India."

Further details of the Society's meetings will be found at the end of this number.

CANTOR LECTURES.

Mr. ALAN S. COLE, C.B., delivered the second and last lecture of his Course on "Some Aspects of Ancient and Modern Embroidery," on Monday evening, 8th inst.

A vote of thanks to the lecturer for his interesting course of lectures was passed on the motion of the Chairman.

The lectures will be published in the *Journal* during the summer recess.

INDIAN SECTION.

Thursday afternoon, May 11; HIS HIGHNESS THE GAEKWAR OF BARODA, G.C.S.I., in the chair.

The paper read was "The Manufactures of Greater Britain.—III. India," by HENRY J. TOZER, M.A.

The paper and report of the discussion will be published in a future number of the *Journal.*

SOCIETY OF ARTS AND LONDON INSTITUTION.

The following Resolution was passed by the Council of the Society of Arts at their meeting held on the 8th May, 1905:—

"In view of the feeling which appears to have been aroused amongst some of the Proprietors of the London Institution with regard to the proposed amalgamation with the Society of Arts, and the consequent probable difficulties of effecting a harmonious fusion of the two Corporations into a single Institution, the Council of the Society of Arts have decided not to take any further action in the matter, and hereby discharge the Committee which, at the instance of the Board of Managers of the London Institution, they appointed to consider the scheme for amalgamation."

PROCEEDINGS OF THE SOCIETY.

APPLIED ART SECTION.

Tuesday afternoon, May 2; SIR GEORGE BIRDWOOD, K.C.I.E., C.S.I., in the chair.

The CHAIRMAN, in introducing the reader of the paper, said that he was well-known as the author of "Armour in England," (1897), "Foreign Armour in England" (1898), and "Ironwork" (1893-6). In 1897, 1900, 1901 he wrote the sumptuously illustrated catalogues of the Burlington Fine Arts Club on "Enamels," "Ironwork," and "Silversmith's work of European Origin;" and in 1904 he brought out his monumental work on "Old Silver Work, chiefly English, from the 15th to the 18th Centuries." Mr. Gardner had already read five papers before the Society, namely, on "Wrought Ironwork," in 1887, on "The Monumental Use of Bronze," in 1888, on "Enamels and Enamelling," in 1891, on "Pewter," in 1894, and on "The Revival of Tradesmen's Signs," in 1899.

The paper read was—

THE MONUMENTAL TREATMENT OF BRONZE.

By J. Starkie Gardner, F.S.A.

Seventeen years ago I had the honour of addressing this Society on the subject of "The Moumental Uses of Bronze." I then confined myself to illustrations of sepulchral monuments. Not many weeks since, my friend Mr. Marion H. Spielmann also read here a paper on Royal monuments, describing those erected and in process of erection to the memory of our great Queen Victoria and her mighty contemporaries, the Emperor William and King Victor Emanuel, all three builders of Empires. There remains, however, a vast field to which not one but many meetings of this Society might be usefully devoted. Commemorative monuments, indeed, may be classified into five great groups: Religious, Sepulchral, Allegorical, Historical, Iconographic, each a subject for separate treatment.

Those designed to honour divinities, lest unseen their awful power should be forgotten, are the earliest of which we have any knowledge. These were visible symbols if not actual habitations of the gods, or temples set apart for their cult. Later, temples were erected with more mixed motives, but always with the dominant, if unexpressed, idea of bettering the life to come. Associated with religious beliefs, they took the practical form of providing places of worship for the people and domiciles for the priesthood. The few other religious monuments, as fountains dedicated to the Virgin, or isolated statues of saints, are exceptions of slight importance.

Another group marks the burial-place and perpetuates the memory of illustrious dead. These sepulchral monuments assumed at times vast proportions, like the Pyramids, the Mausoleum, the Castle of St. Angelo, the Taj Mehal, the Medici Chapel, the Cenotaph of Maximilian, and the Chapel of Henry VII. Like the Wellington Monument in St. Paul's, and the Royal Mausoleum at Windsor, they denote the actual places of interment.

Another more fanciful and poetic group consists of impersonations of the forces of Nature, of the Attributes, Passions, the Past and the Future, as well as concrete things, such as rivers, and people, by means of symbolic or allegorical imagery. The Greeks and Romans delighted in these, and they continue to appeal to the multitude even at the present day. With us no symbols are more popular than Britannia, the British Lion, and John Bull. The series of seated statues of the cities of France around the Place de la Concorde in Paris, erected with no such motive, serve in no small degree to keep green the memory of the losses of the Franco-German war.

An equally imaginative group is the Historical, commemorating auspicious or important national events. These are for the most part set up in public places and take varied forms, the most usual being arches, columns, obelisks, cairns, and allegoric statuary. These monuments, so important among nations of antiquity, had fallen into disuse in Europe until revived by Charles V. and Louis XIV. The Columns of July and Napoleon, our own Monument, the Arcs de Triomphe and du Carrousel, and the Portes St. Denis and St. Martin are conspicuous examples.

The last and by far the most numerous group is Iconographic, or erected to commemorate the deeds, virtues, and appearance of famous personages. These were equally familiar in ancient Greece and Rome, but forgotten later until the classic revival in the Italian Renaissance led to the production of monuments resembling those of antiquity. Our Nelson and Duke of York columns and Albert Memorial are familiar examples, but such memorials more commonly take the less ambitious form of simple portrait statues.

We in England have shown little interest hitherto in monuments commemorating past events, however important, and few are of historic value unless sepulchral. The commemoration of our monarchs and greatest men in bronze or marble was never a national concern until late in the seventeenth century. The men themselves, or their immediate heirs, erected the monuments that exist, as well as countless others that have perished through fire and decay. Had the customs of Greece or Rome by good fortune been maintained, statues would have been set up to most popular heroes of the day, and the likenesses of hosts of interesting personalities preserved and now be familiar to us.

Setting aside sepulchral monuments, with which I do not propose to deal, the most ancient and the most touching is the series of stone crosses erected to mark the resting-places of the bier of the beloved Queen Eleanor, of whom we have fortunately a splendid portrait in bronze in Westminster Abbey. For the most part the crosses have long since crumbled away and been removed, but one especially is perpetuated for ever in

the name "Charing Cross." The sentiment that dictated the erection of these and its mode of expression have remained unique. A long interval elapsed before any other commemorative monument was set up in London, and then it needed nothing less than the apalling destruction of the entire City proper with all its churches and historic buildings, to awake in the English mind a sentiment that had been so predominant in ancient Greece and Rome. "The Monument," so called because there was no other, remains practically unique in England, and except in the naming of Waterloo-bridge and Trafalgar-square, there is no visible sign that the nation cares to perpetuate the great events which have built up its history. But for the Guards' Monument there is nothing publicly commemorating the Crimean war; there is no sign of any national monument in remembrance of our struggles for supremacy in South Africa; and even the arrival of "Cleopatra's Needle" failed to make us realise that in it we possess the most fitting memorial of our occupation of Egypt. Monuments of stirring national events should provide history written large and artistic object-lessons for the people. To ancient historic monuments we are indebted for our sole accurate knowledge of the actual arms and appearance of such mighty historic nations as the Egyptians, Assyrians, Medes, Persians, Dacians, Scythians, Greeks, Romans, Gauls, indeed of every nation that has made up the world's history. A Roman triumphal arch affords the only actual representation of the mystic seven-branched candelabrum of the Jewish Temple, while Trajan's column presents a minutely accurate representation of the chain-mail and weapons that proved as fatal to Crassus, as to the English at Hastings a thousand years later. Our neighbours across the Channel show a thorough appreciation of the value of grand commemorative monuments. The columns of July and Napoleon, their triumphal arches, the Trocadero, the bridges, and names of streets and places keep alive the national glories and chequered career of the great nation. Already most of these monuments are mellowing into historic value, just as in time to come even our indifferent Guards' Monument will serve not only to preserve the memory of our first great struggle with our secular enemy but will record the exact costume of those who fought the battles. How valuable contemporary monuments in bronze would be to us of the heroes and rank and file who won our historic victories. Our pride in our Empire should surely induce us to hand down the presentment of those of us who fight our country's battles, and also of their gallant foes, whether Zulus, Afghans, or others. With no very earnest or successful antiquaries among our living sculptors, it is perhaps unwise to attempt to construct monuments commemorating anything but the immediate past and present, for certainly Boadicea, in her scythed chariot, and the warrior waving a sword in Palace Yard, with bronze bas-reliefs on the pedestal, do not appeal to us as historically accurate; but the great events of our own day, the Union of the British Isles, the Federation of the Colonies, and the Consolidation of our Indian Empire, our political freedom, and that of the Press, might be treated seriously, if competitions were open to all British subjects. An Alfred Stevens may exist among us, or some scenic artist or poetic dreamer might give birth to ideas for the professional architect and sculptor to realise. My own experience is that the power to design and the power to execute do not necessarily or invariably occupy one cranium. The dearth of reasonable presentments of our historic worthies in the public spaces of our metropolis has only been lessened of late by the portrait in bronze of Cromwell; and the Achilles in Hyde-park still remains our only symbolic statue, against the scores set up in other capitals.

Contrasted with those of Paris, our monumental efforts appear insignificant indeed. Emerging a few days since from the Louvre on to the Place du Carrousel, I was at once faced by a series of superb monuments, including that to Gambetta. A few steps west led by the triumphal arch with its bronze quadriga to the Tuileries gardens, where I was confronted with a galaxy of statues and groups, comprising two fine groups of lions, and rhinoceros and tigers, in bronze. Continuing to the Place de la Concorde, I found myself in the presence of the great Luxor Obelisk and two splendid fountains, around which are placed in solemn dignity the great statues emblematic of the noblest cities of France. Beyond, again, are other monuments, including the Marly Horses, the vista being closed by the great Arc de l'Etoile. Grand monuments meet the eye in every part of Paris, and, unlike ours, are effectively placed, and appear to be purposely designed to occupy the positions in which they are seen, frequently amidst trees and flowers. Our monuments, on

the contrary, are generally designed before any position is allotted to them.

In our vast metropolis—laid out for the most part to accommodate the high number of inhabitants by the great landowners, who parcel out the largest part of its area—there are fewer magnificent sites for monuments than in cities laid out by monarchs or powerful corporations. Most of the open places of London are enclosed squares and gardens closed to the public, each of which in Paris would be laid out with palms, plantains, and flowers, and seats around some central fountain or artistic monument. At some not far distant time the happiness of the many may be regarded as more worthy and pleasing than the solitudes of which so few make use. Meanwhile, several fine sites for monuments are available. A new and splendid *façade* to the National Gallery, with loggias and statues, and Trafalgar-square remodelled as a broad approach to it, could commemorate the federation of the Empire. Parliament-square, with its majestic surroundings, would also provide a matchless site for a noble commemorative monument. There are other less important sites, though it is unfortunate that the few commanding spaces at the intersections of main thoroughfares, created by our municipal councils, fit for the reception of beautiful objects, have been seized upon by the sanitary department for underground conveniences which a refined taste would have gladly relegated to equally accessible but less prominent situations.

It must be quite obvious that monuments that tell in London are not the ordinary portrait statues in garments which do not lend themselves to artistic treatment, and on which so many thousands of pounds have been expended without adding one touch of beauty to the town. Monuments to be telling in London must either comprise more than a single figure, or be of larger size than the heroic size sanctioned by tradition or, best of all, be equestrian. A rider on his steed assumes a dignity of pose embodying mastery of an animal many times more powerful than himself, which is most gratifying to humanity. Monuments might assume grander proportions were kindred spirits to be commemorated, associated in groups, or as parts of a whole. Britannia and some of her statesmen might symbolise the union of the British Isles; Neptune, with seamen and navigators our vast maritime power; Victory and warriors a victorious reign. Allegories of Commerce, Science, Peace, Prosperity, Wealth, Fortitude, Charity, Justice, Mercy, Truth, are all capable of artistic treatment, and would elevate the thoughts of the gazer and passer-by, which I take to be the chief reason for setting up monuments, which are not erected merely for

FIG. 1.

ANCIENT PYTHIAN TRIPOD FROM THE TEMPLE AT DELPHI.

pomp and vain glory. Such might take the form of groups, or combine with columns, triumphal arches, fountains, or bridges—which will perhaps provide the most important sites we are likely to acquire in the near future under existing *régimes*. Mediæval bridges with their defensive gates, chapels, and figures

of guardian saints, were picturesque objects. In the cases of Blackfriars and Westminster, we have realised the difficulty of decorating bridges not designed for the purpose of receiving statuary; while visitors to the Paris Exhibition realised on the other hand the surprising possibilities afforded by bridges when designed to be commemorative. Instead of the commonplace pannier-like widening of London-bridge, it might have been converted into a glorious monument to the British Navy; while the new bridge at Vauxhall might have been fitly made to commemorate the services of the Household Brigade in Egypt and South Africa; the purely utilitarian expenses being defrayed as heretofore, and the monumental features by subscription.

I fear I have trespassed on your time by this discursive preface. But the loss, all too recent, of a beloved and one of the greatest monarchs of our history, and the losses incidental to the far-reaching struggle in South Africa, have turned the thoughts of all towards the subject of memorials. The spirit of Empire too, seems in the air, beginning to stir the pulse of the nation, and perhaps ideas now sown, may, like grains of mustard, produce large results in the future.

I shall now proceed to exhibit a very few examples of monuments of the past, limiting them to those of bronze which, in our climate, is the only material suitable for sculpture exposed to the elements. In the short time at our disposal these must obviously be limited to one or two minor groups. Objections and difficulties notwithstanding, it is unlikely that committees who manage these things will set aside the full-length portrait statue. We have no recognised embodiments of the powers of nature, like the Greeks had, Zeus, Athena, or Apollo, to represent and idealise, neither do we commemorate victorious athletes in the nude, nor is the general attitude of the populace encouraging as yet. In ancient times it was one of eager expectancy, and general acclaim rewarded the sculptor when one of his triumphs was set up. This was so in the halcyon days of Greece, Rome, Italy, and it is still seen, to some extent, in France, as we saw at Bordeaux a few days since, when the unveiling of the Gambetta monument amounted to a national fête. Even Germany and other countries contrast favourably with the utter apathy of the English, who seem collectively to have lost touch with everything truly artistic. Added to this is the difficulty of modern costume, which proves an almost insurmountable and always distressing problem to the modern sculptor. If those he habitually commemorated were champion swimmers, oarsmen, football, or tennis men, the matter would be otherwise; but, unhappily for art, those deserving of statues are great statesmen, like Joseph Chamberlain, scientists, benefactors, and so on, and the costume in which we know them best, the tall hat and eyeglass, the immaculate frock-coat and well-stretched trousers, the starched waistcoat and stiff collar, must make artists despair, however well-knit and alert the original may actually be. Only the few can be portrayed in majestic draperies, like kings and German emperors.

With animals, the sculptor is on safe ground; they present their natural grace and beauty unspoiled by art. The most venerable bronze in existence, still resisting the ravages, not of centuries, but of milleniums, and yet retaining its ancient position in the hippodrome at Constantinople, where it was set up as a trophy when Christianity was in infancy, is the ancient Pythian tripod from the temple at Delphi (Fig. 1). It is formed of intertwining snakes, now headless, and the monument is now sunk in a deep pit, a witness to the change in the level of the ground brought about during the centuries it has stood erect at Constantinople.

Once in near association with this, and no less venerable, are the four bronze horses of St. Mark's, removed from the hippodrome by Doge Dandolo in 1204 (Fig. 2). They originated in Greece, probably in the fifth century B.C., and after adorning several triumphal arches in Rome, were transferred by Constantine to his new capital, whence they found their way to their present position over the porch of St. Mark's Cathedral in Venice. They formed part of a quadriga, and were formerly gilt, and are said to be of pure copper cast extremely thin, hardly one-sixth of an inch in thickness, and are thus triumphs of the founder's skill, unless they are hammered work. The head and neck were cast separately, the junction being hidden by the collar. Parts of the horses, being ungilt, show where the trappings formerly existed, and there are holes for its attachment. Their frequent removals have caused injuries to the lower parts of the legs, and some of the gilt trappings and ornaments disappeared after the French had taken them to Paris and been compelled to restore them. The bodies are round, the necks short and muscular, and the heads superb. A bronze horse of the same date, but mutilated, is in the Conservatorio at Rome. The third illustra-

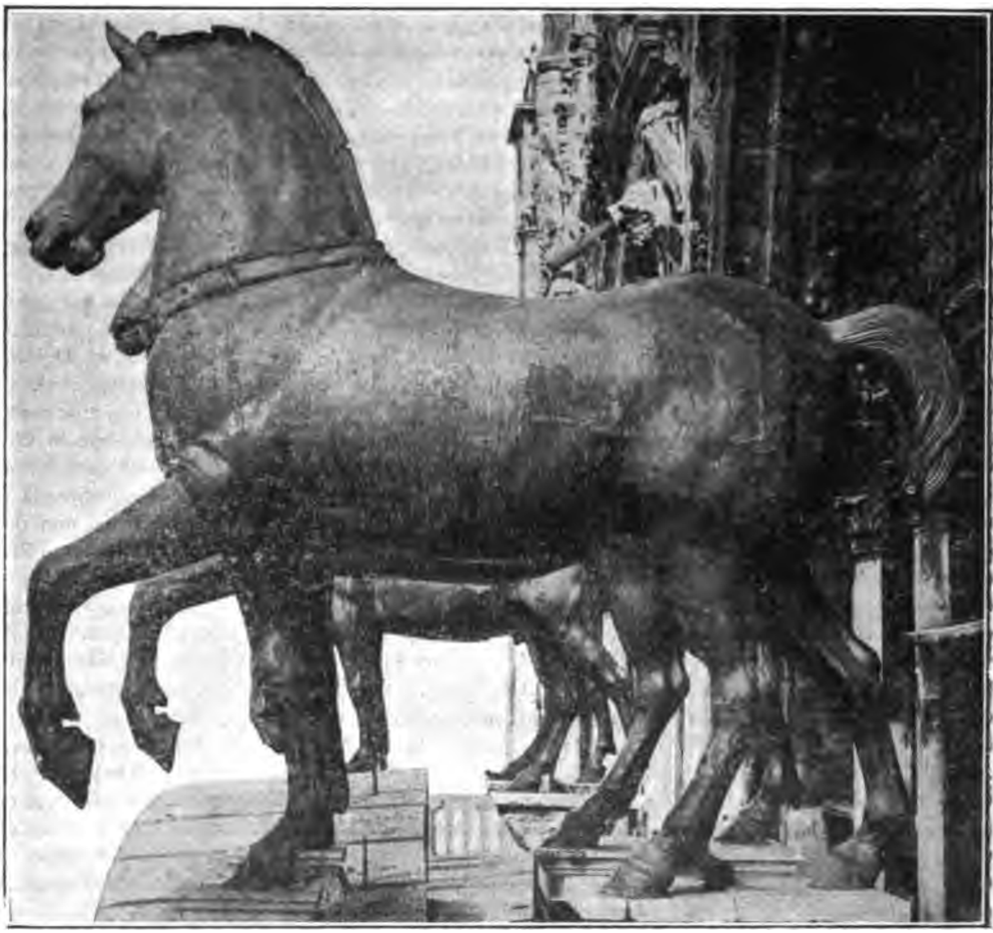
tion is also of venerable antiquity, and by far the most ancient bronze equestrian portrait statue in existence. It stands in the Piazza del Campidoglio at Rome, and was placed on its present pedestal by Michelangelo in 1538 (Fig. 3). The figure is that of Marcus Aurelius, bareheaded and in simple drapery, seated in an easy attitude upon a saddle cloth or saddle of singular construction.

There is a long interval between this and the next equestrian statue, which is said to be of iron, and not bronze. This is the St. George and Dragon in the Cathedral square at Prague, made by Martin and George Clussenbach in 1373, and shows armour partly scaled and partly of plate. It was partially restored in 1562. There is a cast of it in the Victoria and Albert Museum.

There is mention of a cast of an equestrian statue of St. George being in England in the time of Richard II.

Equestrian statues were produced in Italy during the Renaissance, the earliest being that of Gattamelata, by Donatello, in the Piazza in front of the great church at Padua. (Fig. 4). This celebrated commander of the Venetian Army in 1438 is in the armour of the period, truncheon in hand. He is bare-headed, with curly hair and a slight beard. An enormous cross-hilted sword is slung at his side, and he wears the long rowelled-spurs of the fifteenth century. The horse is short-necked, and

FIG. 2.



BRONZE HORSES AT ST. MARK'S, VENICE.

extremely powerful, the tail being twisted into a knot.

An even finer statue is that of Bartolomeo Colleoni, another Captain-General of the Venetian forces, who died in 1475, and was one of the first to use field cannon in war (Fig. 5). He is sheathed in richly decorated armour, and wears the Venetian salade and short rowelled-spurs. The horse, like that by Donatello, resembles those of St. Mark's, but with more vigorous action. The saddle is high, back and front, and richly decorated like the harness; the feet are in stirrups. The statue stands in front of the church of SS. Giovanni e Paolo, in Venice. It was modelled by Andrea Verrocchio, who, however, died in 1488, leaving it to be cast by Alessandro Leopardi, who completed it in 1496. This is probably the finest equestrian statue in existence, the pose is superb, and horse and rider present an irresistible force.

Passing over the French equestrian portrait statues, most of which were destroyed in the Revolution, we come to those of our own country. The only one still remaining of the seventeenth century is that of Charles I. at Charing-cross, by Hubert le Soeur, a French pupil of John of Bologna. It was cast in London in 1633, at the expense of the Howard family, and saved from destruction during the Rebellion by John Rich, a brasier, who presented it to Charles II., in whose reign it was re-erected in 1674. This graceful and commanding bronze statue has been erroneously described as of lead. The same artist commemorated James I. by a bust over the principal entrance to the Banquetting-house, and both James I. and Charles I. by statues now on each side of the choir at Winchester Cathedral. An equestrian portrait of Charles II. was set up in the Stocks' Market by Sir Robert Vyner in 1672, which had a similar fate to the George II., of lead, brought from Canons, the seat of the Chandos family, and set up in Leicester-square in 1754. The statue of George III. in Cockspur-street was not erected till 1837, and is by Matthew Wyatt, and the George IV. in Trafalgar-square was not completed till after the artist's (Sir Francis Chantrey) death in 1843. It would be easy to produce faithful representations of at least Elizabeth, Cromwell, William III., and Marlborough, and who would all form splendid subjects for commemoration in this manner.

Statuary was formerly rendered realistic by colouring, and the material chosen mainly for texture, more than one material being used for producing a single figure. Ivory for the flesh and golden drapery was most favoured, but Parian, Naxian, and Pentelic marble, probably left white for the flesh, with coloured hair, eyes, &c., and drapery, were most often used for female figures. Sometimes the head and limbs only would be marble and the rest of porous stone filled in with stucco and strongly coloured. There can be little doubt as to bronze having been chosen to represent athletes and demigods from its colour resembling the sunburnt bodies of these, and probably the original colour was carefully maintained. Otherwise the pallor of death given to Jocasta by alloying with silver, and the red blush of shame to Athamas, by iron, as Pliny says, would have disappeared under the ordinary patina, even under Grecian skies, after a few days' exposure. We are accustomed to admire bronze for its patina, and to take pleasure in the varying shades of rich browns and greens it assumes everywhere away from our fuliginous cities, and cannot understand the obvious admiration of the ancients for the natural golden glint of the well scoured metal, often replaced by actual gilding. But then we are equally unable to realise their love for polychromatic statuary, the idea of painting or staining marble being repugnant to us. We even dislike, or are slow to replace, the gorgeous blue, scarlet and gold decoration of the carved stone interiors of our perpendicular churches and screens.

Admitting that art bronzes are to be patinated, the question of the best means of controlling and producing the tones becomes of interest. The Japanese excel in this. Our own empiric methods range from inhumation in a dung heap, to suspension up a smoky chimney—preferably where wood or peat fires are burnt, besides acids and alkalis and trade solutions, the components of which are secrets. The exhaustive researches on the cooling of bronze alloys carried on within the past few years shows that the metals remain separate and crystalline, but present structures as diverse as those of the porphyries, gneisses, and granites, according to the rate at which they are cooled. The tones of the more delicate natural patinas would be considerably affected by the internal structure of the alloy. The chemicals useful for the purpose will be found chiefly among the muriates, ammoniates, and sulphides.

The time remaining at my disposal must be given up to a form of monument which was practically never known in England, and

Fig. 3.

Marcus Aurelius, Piazza di Campidoglio, Rome.

the high symbolic import of which is even yet scarcely appreciated.

When not only palaces and pleasaunces, but every edifice, sacred or lay, and every city, was closed with defensible and well-nigh impregnable gates, the question as to whether these would be found open or shut must have been of the most momentous. The hope of the night's shelter, warmth, and food hung upon the contingency, and oft the traveller must have been met with the stern rebuke, "Too late, too late; you cannot enter now." Inevitably the imagination fenced in the places to be desired in a future life with gates, inexorably closed except to the favoured few. The keys of the gates of Heaven or Paradise were committed to St. Peter, rarely to be opened to anyone without intercession, but the gates of Hell and Purgatory gaped wide. Open or shut, gates were the focus of interest, and could not be approached in primitive days without awe, curiosity, or emotion. It is hence not surprising that they were sumptuously and magnificently decorated. The Roman triumphal arch was only the apotheosis of the gate, recalling difficulties gloriously overcome. The question, figuratively, of the open or closed door to commerce is almost the only one about which civilised nations might still go to war.

In the days when iron was little used, the massive wooden doors were sheathed, for protection from fire and for strength, in bronze, and revolved upon massive bronze hinges. Upon these were sometimes pictured the mighty deeds of the monarch of the country. The bronze portions of two pairs of enormous doors were found many years since by Mr. Harmuzd Rassam in excavating at Balawat in Assyria. The city contained a palace standing in a long rectangular enclosure, with four entrances, near two of which the remains of the doors were found. The larger were about 22 ft. high, 6 ft. wide, and 3 inches thick, each leaf being attached to a cylindrical post, about 18 inches in diameter, to which strong bronze pivots were fixed, working in stone sockets. Across each door seven or eight plates of bronze 11 inches wide were fixed by nails at regular intervals, these plates lapping round the post. On each of these plates are representations of the Assyrian army on its war path, and other events of the first 9 years of the reign of Shalmaneser II. These are in two bands of *repoussé* work, executed with great fidelity and spirit, and much freedom of drawing. Between embossed bands narrow spaces are left, relieved at regular intervals with the rosettes through which the nails are passed that fixed the plates to the woodwork of the doors. The "brazen gates" of antiquity were probably of this kind, and we are singularly fortunate in the possession of these splendid examples by our national museum.

Of the Roman period, there are several bronze doors, but of a different type and not depending on wood for their construction, still preserved in Rome itself. These are the large central doors of St. John Lateran, decorated with foliage, and brought from the Æmilian Temple in the Forum, and of about the date of Our Lord. Another pair, brought from the baths of Caracalla, and of about the third century, close the oratory of St. John the Baptist, in the church of S. Giovanni in Fonte, the ancient baptistery in Rome. The vast bronze doors of the Pantheon remain in their original position, dating possibly from the time of Agrippa, 31 B.C. The doorway of marble, 39 feet high and 19 feet wide, contains their massive framing, consisting of two bronze pilasters, to which the doors are hinged, and the lintel over them which is a pierced bronze scale pattern grille. The doors themselves are not decorated in relief, but are of severe and dignified simplicity.

Next in point of antiquity are the Byzantine gates which revert to the partly wood construction of the East. Examples of these still exist in Constantinople, but the best known are the bronze doors to the vestibule of St. Mark's, in Venice. Some of these were brought from Constantinople, it is supposed from S. Sophia, after its reconstruction by Justinian, and may date back to the sixth century. Three of the oldest are divided into four panels of double arches with crosses and foliage rising out of vases under each arch. The other two are in the later Byzantine style, the central one, of early eleventh century, divided into forty-two framed panels inlaid with figures of saints in silver, the heads of some in relief, and a lower row of six panels decorated with bosses only. The frames are broad and studded with bossed nails, and twisted pillars separate each row of panels vertically. The remaining door is treated similarly, but divided into twenty-eight panels with figures, and is older since the inscriptions are in Greek characters. The framing of the panels are richly decorated with geometric and florid designs, and there is a central row of six lions' heads among the bosses. In the large

FIG. 4.

GENERAL GATTAMELETA, BY DONATELLO, AT PARDUA.

central doors these are replaced by a row of eight lions' heads with rings, and the inscriptions identifying the prophets and saints are in Roman characters.

Next in age are the principal doors from the venerable Abbey Church of Monte Cassino, executed by order of Abbot Desiderio, later Pope Vittorio III., 1088. They also are inlaid with silver curiously reciting a list of the properties held by the Abbey in 1066. The crosses at the base are like those of the earlier doors of St. Mark's. The Cathedral at Amalfi has doors similarly ornamented; and the doors of the Cathedral at Salerno, erected by Robert Guiscard, are also inlaid with silver, and were executed at Constantinople in 1099. Other examples exist.

The central doors of the Cathedral of Benevento are divided in seventy-two panels, filled with bas-reliefs, except four containing lions' heads with ring handles. Those above represent scriptural scenes crowded with figures, and below are single saints under simple canopies. The framing is made of egg-and-tongue moulding, with large rosettes at the intersections. They are supposed to have been made in Constantinople in 1150.

There are exceedingly interesting bronze doors at Canosa closing the Mausoleum of Boemond, the son of Robert Guiscard: portions of the cathedral doors of Susa, of Byzantine eleventh century work, are preserved in the treasury of that cathedral.

FIG. 5.

BARTOLOMEO COLLEONI AT VENICE.

Bronze doors of Italian make first appear in the twelfth century, the earliest artist of whom we have definite records being Barisano da Trani. The bronze doors to Trani cathedral, made in 1160, are his work, and are divided into 32 panels of subjects in relief with rich scrolled borderings, and mounted on hard wood. The side doors of Monreale are by the same artist, but somewhat later, divided into 28 panels with reliefs and excessively rich borderings. Even finer are the doors of the Cathedral of St. Pantaleone, at Ravello, by the same artist, and produced in 1179. The figures are

very varied and of some merit, considering the date, and constitute a landmark in the history of Italian art. Equally celebrated for bronze work is Bonanno da Pisa, who produced the great central doors of Monreale in 1186. The entrance is arched and richly sculptured, and the doors are divided into 40 small panels, with scriptural subjects in relief, and in plain frames studded with rosettes, and separated vertically by bands of acanthus foliage treated conventionally. At the base are two lions and two griffins, and above are enthroned the Saviour and the Madonna with angels. To the same artist we owe the doors of the Baptistery at Pisa, less important as to size, but more delicate in design and workmanship. To the last year of the thirteenth century belong the well-known open-work scale pattern doors of St. Mark's, Venice, inscribed "MCCC + Magister Bertucius Aurifex Venetus me fecit +." The details of these are noteworthy.

The doors of S. Zeno Maggiore at Verona are in the Italian style, but have been assigned to an unknown German artist, who produced them in 1178. They comprise 48 panels with scriptural subjects in relief and two with large heads, serving as knockers or closing rings. They betray a slight tendency to the grotesque, but the architectural details seen in the panels are of great interest, suggesting an Italian source.

With the appearance of Andrea Pisano in the fourteenth century, we reach more familiar ground. He was commissioned in 1311 to make the doors to the baptistery of the cathedral in Florence, designed by Giotto, being regarded as the best artist for the purpose to be found in all Italy. They occupied 22 years, notwithstanding the assistance of his son and two fellow artists, Lippo Dini and Piero di Jacopo, and were cast in Venice by Master Leonardo del Avanzo, and finally gilded by fire in 1339. They were shifted from the northern entrance to make way for the gates by Ghiberti, and re-erected at the south. They consist of 28 panels with scenes from the life of the Baptist in relief, placed in barbed quatrefoils with rectangular moulded framing, studded with bosses and lion heads in relief. When they were set up the Signory came in solemn state to applaud the artist and confer on him the dignity of citizenship. The architrave was added by Ghiberti, who made a corresponding pair of doors or the northern entrance in 1403, when he was but 22. These occupied 21 years, though many assistants were employed, including his father-in-law, Bartoluccio, a great silversmith. They weighed 34,000 lbs., and cost 16,204 florins. Founded on the work of Andrea Pisano they nevertheless show marked progress in Italian art. In 1425 the same Lorenzo Ghiberti was commissioned to execute the central doors, spoken of by Michel Angelo as worthy to be the gates of Paradise. They mark an entirely new departure, a striving for pictorial effects, to an extent never before attempted. Ghiberti has left on record that he "strove to imitate nature to the utmost, and by investigating her methods of work to see how nearly I could approach her. I sought to understand how forms strike upon the eye, and how the theoretic part of sculptural and pictorial art should be managed. Working with the utmost diligence and care, I introduced into some of my compositions as many as a hundred figures, which I modelled upon different planes, so that those nearest the eye might appear larger, and those more remote smaller in proportion." Perhaps the novelty led to the somewhat exaggerated praise. The founding was commenced in 1440 and completed in 1452 at a total expense of 14,594 florins. They thus occupied 27 years, or, according to Vasari, 40! The scenes are from the Old Testament, and fill the 10 panels. The framing comprises 20 statuettes in niches and four recumbent figures, and 24 heads in the highest relief, among them one of the sculptor himself. The framing of the doorway, also of bronze, comprises foliage, fruit, flowers, and numerous animals and birds, all in high relief.

Florence also boasts two small pairs of doors by Donatello for the sacristies of the church of S. Lorenzo, with 10 panels in relief of saints and martyrs. These were produced in about 1457, 11 years before his death. There are also bronze doors to the sacristy of the cathedral by Luca della Robbia, executed in 1464, comprising 10 panels of subjects in high relief, which have almost the finish of silverwork, and were highly commended by Vasari.

A pair of magnificent bronze doors were cast for the Triumphal Arch of the Castel Nuovo at Naples, erected by Pietro di Martino for Alfonzo of Aragon to commemorate his entry into the city in 1443. They occupied 19 years, not being finished until after his death—a grief to a prince known as the Magnanimous, and a great patron of art. Guglielmo lo Monaco of Umbria completed the work in 1465. They are divided

into six large panels, the two uppermost forming segments of an arch, all crowded with figures of mounted men-at-arms in battle array, with citadels in perspective in the background.

The art of bronze-founding had, no doubt, attained its zenith in Italy in the fifteenth century, yet to the sixteenth belongs the superb door to the sacristy of St. Mark's, Venice, by Jacopo Sansovino, produced about 1529, when he was appointed architect and sculptor to the Venetian Republic. It is divided into two panels, with scenes from the life of Christ, bordered in the manner of the later Ghiberti gates, the portraits being, however, of great interest, since they are those of himself, Titian, Aretino, Paul Veronese, Giorgione, and Tintoretto.

The front of the cathedral at Loreto has three pairs of most sumptuous doors, the central by Girolamo Lombardi, of Ferrara, and his sons, who worked on them from 1534 to 1560. They comprise six large and eight smaller panels, illustrating the story of Adam and Eve, with richly worked borders. The left-hand doors are by Tiburzio Verzelli da Camerino, of somewhat later date, but corresponding generally in design, and those on the right by Antonio Calcagni, each having employed several assistants.

The seventeenth century produced the three magnificent doors to the Cathedral at Pisa, by John of Bologna, executed in 1602, evidently inspired by the later door of Ghiberti in Florence. The principal panels represent scenes from the life of the Virgin, and the borders comprise branches of laurel and of orange, roses, figures, &c, with a considerable tendency to realism. He employed several assistants.

The last of the illustrations shows the bronze gates of the Campanile Loggia in Venice, to our taste perhaps wanting in repose, but comprising some fine modelling. Gates of this sort are almost confined to Italy, and few exist anywhere wholly of bronze unless closing an arch or entrance. Little appears to be known of the artist—Antonio Gai.

It may have been noticed that the doors were originally modelled on the lines of the strongest form of wooden doors known, and the interspaces occupied by the panels are therefore necessarily reduced to very small dimensions. Ghiberti was the first to abandon the strongly constructional form and introduce larger panels, and these were generally adopted, until in the doors at Naples there are only three panels to each leaf.

In England we have rarely since mediæval days, when splendid iron-work was laced over doors to give them strength, been conscious of the decorative value of metal for doors, though the Italian artists had for centuries lavished their finest work upon them, and many were famous *chefs d'œuvres*. The oldest bronze gates we have close the entrance to Blenheim Palace. In London there are bronze gates closing both the Marble and Wellington arches, and there is a pair in the central arch to Buckingham Palace. Those for the Marble Arch cost 3,000 guineas.

There are many occasions when relatively small sums are available for commemoration, and many sites where beautiful gates, whether of iron or bronze, would add greatly to the importance and dignity of the scene. Memorial gates can be and are produced at from £60 to several hundred pounds, in iron, and I have plans before me for bronze gates running into thousands. When these are executed it may be interesting to describe the process of manufacture from the commencement. A very fine pair of bronze doors for a Liverpool bank is illustrated in the "Encyclopædia Britannica" under Art Metal Work.

In conclusion, I have to express my thanks to Sir George Birdwood, our Chairman, for his kindly introduction, to Mr. William Reid, of Lauriston Castle, Midlothian, who obtained for me during his recent tour in Italy the illustrations you have seen, and to Lady Theodora Guest for most kindly translating the descriptions of the gates, which I have made use of, from the original Italian.

DISCUSSION.

The CHAIRMAN said that deeply grateful as they must all be to Mr. Starkie Gardner for his learned and most inspiring paper, and, he must add, most illuminative lantern slide "demonstrations," he was himself under a special obligation to Mr. Starkie Gardner. He had for over twelve years been seeking for a paper to be read in the Applied Art Section of the Society of Arts in continuation of the paper given by Mr. Starkie Gardner eighteen years ago on bronze work; but he had sought for it in vain until this year he found that Mr. Starkie Gardner was prepared to read a second paper on the subject provided that he himself undertook to occupy the chair on the occasion. In justice to himself he must add that when he consented to do this it was on the understanding that Mr. Starkie Gardner would treat of bronze work with the special object of promoting a revival of the ancient use of bronze in jewelry; and

he never anticipated that Mr. Starkie Gardner would devote his paper to an erudite exposition and an eloquent eulogy of bronze in its application to monumental statuary and architectural decoration. He had a natural feeling for applied art, and he hoped a sound judgment on it—in its more homely and familiar departments—and for sixty years he had with more or less responsibility given himself up to the study of its commercial and literary history; but he knew nothing of the so discriminated "fine arts," and he therefore felt himself in something of a false position in filling the chair that evening. It was not for him, he felt, to look up into the face of "the blue-eyed Maid," whose content it was to bow himself humbly down to the shadow of the latchet of of her "beautiful shoes,—ambrosial and golden" [*kala pedila, ambrosia, chruseia*, Od: xxiv., 340-1]. But as one of the general audience he had appreciated Mr. Starkie Gardner's paper as gratefully as anyone present, and in that sense no one was better qualified than himself to convey to Mr. Starkie Gardner the expression of their most hearty thanks for the charmed hour of instruction and delight they had all been privileged to pass with him. He would call on others to speak on Mr. Starkie Gardner's paper from the author's own standpoint; and all he himself proposed to do was to supplement Mr. Starkie Gardner's paper with a summary explanation of the etymologies of the words copper, bronze, and brass, for such explanations often throw much light on the earlier, unwritten history,—the pre-history,—of the industrial arts; and an equally brief reference to the copper, bronze, and brass work of India,—India of the Hindus,—as this would be found full of unexpected significancies not only for workers in the great metallurgical handicrafts, but also for the students of sacred iconography and doctrine and ritual. Brass, the alloy of copper with zinc, although said by some to have been unknown to the Greeks and Romans [who, however, probably used it as familiarly as the Hindus have always done, and in common with bronze], bears in the name by which we discriminate it from bronze the stamp of its high antiquity, the word "brass" being the Icelandic *bras*, "solder," from *brasa*, "to (harden with) fire" [compare "braze," "brazier," &c.], cognate with the Sanskrit *brajj*, "to burn," "roast," "fry." Bronze, the alloy of copper with tin, has been known from the first use of copper in Egypt, Assyria, India, Greece, the world of Rome, &c.; but the word "bronze" is not older than the sixteenth century, being the Italian *bronzo* [received by us through the French *bronse*], "scorched," remotely cognate with "brown," "bruin," *i e.*, the *brown* bear, "burnt," burnish, brew, and more remotely with brass." The etymology of the word copper is more concisely traceable forwardly than backwardly:—Sanskrit *ayas*, "copper," then "metal," and, finally, in the form of *kala-ayas*, "iron," *i.e*, "black copper," [compare Homer's frequent *chalkos aithops*, "black copper," *i.e.*, "bronze," and *chalkos eruthros*, Iliad ix., 365, "red," *i.e.*, "native, copper"], and *loha*, "copper," but now exclusively "iron" [*pitala*, literally "bile-coloured copper," now signifying enclusively "brass]"; Old Persian *ayan*, "copper," then "iron," *ayan-hæna*, "metallic," literally "made of copper," or "made of iron," *ayokshusta*, "molten copper" [compare Greek *chalkos*, and also Semitic *nchoset*, Chaldee *nechaseh*, Syraic *nechosch*, Arabic *nuhas*, and the "Nehustan" of 2 Kings xviii. 4 = "Brummagem"]; Umbrian *ahenum*, "copper," and Latin *ahenum*, "a copper" cauldron ["caldron" being the Latin "caldaria," French *chaudiere*, but compare Greek *chalkos*] "aenus" "copper coloured," "signum aeneum," "a bronze statue"; and again "æs Cyprium," "Cyprian copper," *i.e.*, bronze or brass, in Low Latin "cuprum," "copper"; [compare "*gopper*-wood," of Genesis vi. 14, which if correctly identified with "Cypress," means "Cyprian-wood"], and Gothic *ais*, "copper," German *eisen*, "iron," Anglo-Saxon *iren*, "iron," and English "harness," "era," "ore," "iron," and again from the Low Latin, "cuprum," "copper," the Spanish and Portuguese *cobre*, French *cuivre*, German *kupfer*, and Dutch *koper*. It is generally assumed that the metallurgy of copper originated in pre-Semitic Assyria, and the Sumiro-Akkadian for copper, *urudu*, "fiery red," cannot but be connected with the Latin "raudus," "'slug'-copper," and "rudis," "rough," "unwrought," "unformed," "untilled," "rude"; and with the Baluchi and Old Persian *rod*, and Modern Persian *roi*, "copper"; and the Greek *eruthros* "red." But in a Sumiro-Akkadian hymn to the God-Smith of copper [*urudu*] and tin [*anak*] he is addressed [compare Tubal-Cain, Genesis iv., 22] as *Gibil*, a name resembling the Albanian *jebjiti*, literally an Egyptian [compare Gipsey], but meaning a "smith," and suggestive of the possibility of the Sumiro-Akkadians having acquired their knowledge of copper, and the art of working it, from Egypt. Certainly the Egyptians were acquainted with copper [*chomt*] from the earliest period of their Pharaonic history; while it would appear equally certain, from the etymologies above given, that it was through Asia, and not directly from Egypt, that the Aryan races of Europe acquired their earliest knowledge of copper. How primitive man came to discover copper and the other metals, and to use copper and iron for arms, implements, and utensils, is told by Lucretius [v., 1250-5] and Horace [Sat.: I., 3] with a vividness of detail the accuracy of which has been confirmed by the researches of modern ethnographers. The xxxivth Book of Pliny's Natural History is "the classical place" for an account of the monumental use of copper, by the Greeks and Romans; and it is a truly wonderful bequest to every student of the history of "the fine arts," for he therein enumerates 366 artists, with their most celebrated works in brass and bronze. In India there is no end of the store of copper and brass domestic utensils; while the treasure of brazen vessels and lamps,

and other sacred furniture, and of sacrificial implements in the temples is infinite; and the use of copper, and bronze, and brass for images of the gods is absolutely prodigious; and much is used also on some temples for the adorning of the panels of the folding doors, and their jambs and lintels, and thresholds, and of the clustered columns, and the bold architraves they upbear. The ring of the coppersmith's hammer, as sonorous and clear as the echoing note of the little green barbet [*Megalaima viridis*] called after him, cheers the weary wayfarer from every throbbing village of the upland steppes of the Deccan; and the clangorous coppersmiths' bazaar is always one of the most animated and inspiriting sights of the greater polytechnical cities of Western India. Wooden images of the gods are lawful only in the temples, and may not be used in private houses, and this may be the reply to Pliny's exclamation of wonder [xxxiv. 16 (7)], that notwithstanding the high antiquity of stone and metal statues of the gods in Italy, those in the temples were either of wood or earthenware. In India the clay images of the gods are worshipped both in temples and private houses, but they must be thrown into some sacred stream or tank after being once worshipped. Similarly, all domestic utensils of clay have to be broken into sherds by the Hindus after once using them. When the late Sir Henry Doulton first heard this statement in this very room, he sympathetically cried out:—"What a Paradise for the potter." Stone images, most of them black, but some white, are common in all temples, and may be set up also in private houses, but there they are usually of small and even minute size, and of crystal or precious stones. Images of all the gods [graven or molten] in all the metals, gold, silver, tin, quick-silver (with tin), copper, zinc, and lead, are also worshipped both in the temples and private houses; but only the images of the wives of the gods are of gold, as of Saraswati the wife of Brahma, "The Lord Creator"; Kali the wife of Shiva, "The Lord Destroyer"; Lakshmi the wife of Vishnu, "The Lord Preserver"; and Radha the mistress of Krishna, "The Lord of the Joy in Life"; and this is because these goddesses are the representatives of the highest glory and praise of the gods. All the images of the gods must be of a polished, or sparkling, or resplendent surface, or be brightly painted. [Compare Pausanias ii., 2.5, vii. 26.11, and vii. 39.6.] They must always shine, if only in their names, just as the Roman god of war shines in his name of "bright" Mars; and this explains the use of marble [Latin "marmor," and Greek *mar-mar os* "the doubly," "the pre-eminently shining stone,"] in the divine imagery of the gods of Greece and Rome. The standard lamps of the Hindu temples built up in a conventional similitude to trees in full foliage, and laden with flowers or fruits, are truly glorious objects to look upon at the hour of evening service ["Hymnus ad incensum Lucernæ"], when all their fruits or flowers are lighted up, and the whole tree quivers into the light as of its own irradiant life. Such was the candelabrum Alexander the Great took away from the sacking of Thebes and dedicated to the Temple of the Palatine Apollo at Cyme [Pliny xxxiv. 8 (3)]. Mr. Starkie Gardner's paper was obviously pertinent to the actualities and interests of a moment when Londoners were awakening to the duty of rendering their city,—"this God Protected, wonderful Tree of Life," as a former Sultan of Zanzibar, Seyyid Bargasch, phrased it while here in 1875—more worthy, in the "setting out" and architecture of its reconstructing streets and squares, of its place of authority and pride in the history of these islands. The most spacious, the most commodious, the most populous, and the most opulent of the marts of merchandise yet known to man, by its free hospitality toward "all they who go down to the sea in ships, and do business on great waters," even more than by its natural opportunities of position, London has during the past thousand years become the centre of the traffics, and drawn to itself the trade and wealth—"the peaceful commerce from divisible shores"—of the whole habitable globe; and Mr. Starkie Gardner's paper in its motive and expression was another impressive warning that the critical time has arrived, and cannot longer, with any safety, be procrastinated, for a determinate, sustained, and conclusive effort to make this the most famous of modern cities, also the most stately and beautiful; and a pre-eminent, exemplary, and imperishable symbol of the genius, achievements, and renown of the English speaking peoples, not only of the United Kingdom, but settled throughout the world in all their several States, Dominions, Commonwealths, and Confederations. This was the immediate purpose of Mr. Starkie Gardner's paper, to which he—the Chairman—would desire to direct the attention of those who followed him in the discussion on it.

Mr. HUGH STANNUS thought the paper was one of the most interesting which had been delivered before the Applied Art Section of the Society, illustrated as it had been by so fine a collection of lantern slides. It was possible to deal with the subject from three points of view—the technical, the æsthetic, or that of storiation. A man might speak of bronze, with reference to its alloys, and the method of working, which would be its technical side; or he might speak of it, having reference to its qualities, as fine art, which would be the æsthetic side; or he might speak of it in reference to the story it had to tell to the people who looked upon it in all years, which was the storiation side of the subject. He was very much interested to notice how much attention the author gave to the last. Bronze, by reason of its being so noble a metal, and having the power of permanence, lent itself especially to telling a story to those who came after. The author had spoken very feelingly about the unfortunate manner in which the important spaces at the intersection of main thoroughfares were

desecrated by institutions which though useful might very well be placed in less conspicuous positions. While the author was speaking on the subject, he was reminded of the decorative treatment at the crossing of four streets in the City of Rome. Mr. Gardner would recollect the street which runs from the Pincian Hill to the Santa Maria Maggiore, which is crossed by the Via del Quirinale, four pieces of sculpture on fountains being placed at the corners, the street hence being called Via Quattro Fontane. He supposed that in modern mercantile days people would object to putting up fountains which would waste space that might be occupied by shop windows; but they had a very monumental effect in Rome, and it was well worth considering whether treatments of the same nature could not be carried out in London. The author had referred to Blackfriars and Westminster bridges, and had stated that people realised the importance of decorating bridges as well as building them. Blackfriars-bridge was designed with pedestals for groups of sculpture, and Westminster-bridge was not; and by that curious method of doing what ought not to be done, and leaving undone that which ought to have been done, a group of sculpture had been placed at Westminster, whilst Blackfriars-bridge remained tenantless, so far as its pedestals were concerned. With reference to the statuary for Blackfriars, he was reminded of the competition which was held many years ago for designs for sculpture to occupy the four large blocks of pedestals. Judges were appointed, who went about their work in the wrong way. The competition was for *designs* and not for *modelling* only; but the judges awarded the competition entirely for the modelling, the result being that the competition was a fiasco. Among the designs sent in were some which would have been good for the spaces, but the prizes were given to modelled equestrian statues. The Boadicea on Westminster-bridge was a fine piece of work, but he would like to see that piece of sculpture applied to Blackfriars rather than to Westminster-bridge. The author had referred to the ivory, the gold, and the mixing of the various materials in polychromatic statuary. He submitted for Mr. Gardner's consideration whether those materials were not intended for protected statues which were placed indoors. They read of the chryselephantine statue in the Parthenon, and the chryselephantine statue to Zeus at Olympia; but the mixing of the various materials would leave joints or crevices between the joinings of the materials which made them unsuitable for outdoor statues. As the author had so admirably said, the Greeks had not that objection to colour that people in Puritan England seemed to have, and they therefore mixed not only marble, ivory, and metals, but also enamels in a very delightful manner. The author had also referred to Gates and Doors, and had shown a very fine series of slides which must have involved an enormous amount of collection. He thought the thanks of the members were particularly due to the author for his admirable illustrations, and his remarks upon them. He was reminded of two designs for doors by British artists, the first of which had not been carried out, but the drawings of which were at South Kensington, namely, the design for the doors of the Geological Museum in Piccadilly, which he included in the illustrations of his Book on Stevens. Happily the designs and models of a pupil of Stevens for another pair of doors had been executed, and were at the South Kensington Museum, serving as the doors from the Quadrangle to the Refreshment Corridor. Small as they were, they were admirable in style. He would like to contest Mr. Gardner's complaint as to the time taken by the Italian artists. First of all, he submitted there was no authority for supposing that the gates designed either by Ghiberti or Pisano were their *exclusive* occupation during the 20, 22, or 27 years upon which the author had commented. Those artists might have had other commissions on hand, indeed it was extremely likely they had. And, when one read, for instance, in the Biography of Cellini, of the manner in which the artist's time in those days was cut to waste by his noble patrons, he thought they should have a good deal of sympathy with the artists. He knew of a modern monument in St. Paul's Cathedral which took something like 20 years to complete. If it took 20 years to complete the central Ghiberti gates, they were well worth waiting for. In conclusion, he could not help feeling that the author had touched on only the fringe of the subject, and what was really needed was not a solitary paper but a Course of Lectures which would give material for a future hand-book on the subject.

Mr. S. B. GOSLIN said the subject of the paper was very interesting to him because bronze founding was his everyday occupation. He thought the apathy of the British public towards bronze founding was attributable to two facts, firstly, that the Founders' Company, to which both Mr. Stannus and himself belonged, did nothing whatever to foster the art in London or in England. He thought it was time the Founders' Company altered their course of procedure. An Exhibition was held a few years ago of what was supposed to be British or London founding, and it was a great difficulty for the Master and Wardens at the time to find sufficient specimens to make an exhibition. He believed the Exhibition passed off with the usual lunch, and nothing had been heard of British founding since. In walking past the School of Trades in Cleveland-street, near the Middlesex Hospital, he anxiously looked down the list of subjects on which instruction was given to workmen to see if founding was among the subjects taught; but although carpentry, masonry, bricklaying, and sheet metal work were taught, founding was not. It was not to be wondered at that the art of bronze founding did not advance when so little was done for it in this country at the present time. Since the cessation of the Boer war, however, he had been astounded to receive so many enquiries

for all sorts of articles in bronze, such as monumental tablets, figures, and ornaments. He supposed that at no previous time within the history of the country had there been such a demand for bronze work connected with monuments as there had been since the Boer war. A variety of designs for figures, tablets, and ornaments had been placed before him, and he knew that several of them had been excellently carried out. It seemed to him that at the present time people were really waking up to the fact that bronze ornaments were the most suitable in this country for such work as the author had mentioned. Mr. Starkie Gardner had not mentioned in his paper anything about the bronze work carried out in the time of the Egyptians or the Israelites. It was his privilege a short time ago to be amongst some Jewish ministers who wished to decorate their synagogue at Stepney Green, East London, and he at once suggested to them that the columns of the synagogue should be decorated with bronze, as bronze had been freely used in Solomon's Temple. He was happy to say they fell in with the idea, and representations were placed on the columns of the synagogue of the fruits of the Holy Land, such as grapes, figs, olives, and so on. He had also made a great many mausoleum doors in bronze, all of the plain type, with one exception. He had recently been called upon to make a decorative mausoleum door, the model representing Christ as the Good Shepherd. It was now attached to a mausoleum in the cemetery of the Necropolis Company at Woking, and was much appreciated by many people who had been to see it. He was inclined to think that that style of decoration in monumental work would increase. He would like to ask the author whether the panels in the ancient Italian doors which had been shown were cast separately, and then put into the frame, or whether they were cast in one piece, and what was the thickness of the doors.

Mr. STARKIE GARDNER said they were all separate, but the other question he could not answer off-hand, but the thickness could be ascertained by comparing the weight with the size.

Mr. GOSLIN, continuing, said that probably one reason why the artists in ancient Italy spent so much time over their work might have been due to the fact that they had to make several castings before they obtained a perfect one, a large casting being so liable to warp when it was cooling. He remembered on one occasion he had to cast a large monumental tablet 8 ft. by 4 ft. 6 ins. for the cathedral at Madrid, and he had to make three castings before he obtained one which was anything like flat.

The CHAIRMAN stated that in the instances of the Indian doors to which he had referred the panels were all separate, and beaten. He suggested that Mr. Goslin should go and see the Indian doors, particularly the bronze ones, at South Kensington. Personally he did not see why Indian workmen should not be imported into this country to do this sort of work. It would wake our Trades Unionists up a little if they saw how much better the Indians could do such work.

Mr. CYRIL DAVENPORT stated that his sympathies were more with hammered work than cast work. There was no doubt that the bronze horses at Venice and the statue of Colleoni were the finest pieces of bronze work in the world, but the horses had hitherto been generally considered to have been cast. Mr. Gardner had stated they might be hammered, and if so they were the finest pieces of hammered work in existence. It was a curious thing, but he had ~~recently seen~~ at the St. Louis Exhibition, some Japanese hammered work, which was absolutely in the round, which showed that, strange as it might seem, the author's conclusion was quite possible. He presumed Mr. Gardner thought the bronze horses must have been hammered-up piece-meal, and soldered together in places, but the Japanese work was hammered-up from a flat sheet of iron. It was most remarkable work which he had not seen noticed anywhere.

The CHAIRMAN enquired if there were two sheets, one for each side.

Mr. CYRIL DAVENPORT replied that there was only one sheet. The ancient Greeks did some very wonderful work in bronze; they hammered up a few small pieces in the round, or very near it, but he never saw a piece of work anywhere which was of such marvellous technical skill as the figures in the round done by the modern Japanese, and if the Japanese could do it to-day the ancient Greeks might have been able to do it in former days. Mr. Gardner's statement was a very remarkable one, and was probably quite right, because to cast horses with the wonderful grace they had must have been excessively difficult. He agreed with the Chairman that there was a very large field indeed for bronze jewellery, but he hoped it would be hammered and not cast. Cast work might be made from a piece of hammered work, but in the hammered work one obtained the actual handiwork and skill of the artist, which was not the case with cast work unless it was chased over, as one of the wonderful doors which had been shown was.

Mr. E. R. ROBSON said the mention which had been made of the bronze horses at Venice recalled to his mind that some years ago he saw an equestrian statue, ostensibly of bronze, unveiled in the City of Durham; and as the sheet was drawn off the whole thing quivered. In subsequent conversation with the sculptor he enquired what the core of the statue was made of; and he ascertained that the film was only about one-eighth of an inch thick. He did not think the horses at Venice were entirely of wrought bronze; and it had occurred to him that if modern men thought about old methods there might be some old method by which the core could be made of

wax, which could afterwards be melted and got out, leaving the metal very thin indeed.

The CHAIRMAN, in proposing a vote of thanks to Mr. Starkie Gardner for his paper, said that beyond its technical value its literary merit also was higher, and he was sure it would always be referred to in the future by those who wished to deal with the same subject.

The resolution having been carried unanimously, Mr. Starkie Gardner briefly acknowledged the compliment, and the meeting terminated.

Mr. STARKIE GARDNER writes:—I should like to add that some of the bronze statues of Greece, in their best period, were hammered out of sheet, and not cast. Two remarkable monuments I should have alluded to, though they no longer exist, were the Umbilicus Romæ, marking the centre of the empire, near the Roman Forum, a cone-like structure of three stages of stone carved in a network of metal. This, perhaps, reproduced the sacred omphalos at Delphi. A central monument of the kind might well occupy the centre of the wide end of Parliament-street. The other was the Milliarium Aureum, a gilt bronze pillar set up by Augustus, with the names and distances of the gates of Rome from the central point, and the chief towns on the roads which radiated from Rome. Charing-cross suggests itself as the site for such a monument.

TWENTIETH ORDINARY MEETING.

Wednesday, May 10, 1905; J. CATHCART WASON, M.P., in the chair.

The following candidates were proposed for election as members of the Society:—

Bodie, Samuel Murphy, D.Sc., Macduff, N.B.
Drury, Henry George, M.V.O., St. Oswald's, Downs-road, Clapton, N.E.
Eldred, Byron L., 208, Fifth-avenue, New York City, U.S.A.
Garside, Alfred B., 1a, Dennington-park-mansions, West Hampstead, N.W.
Harvey, Frank E., British India Marine Service Club, Hastings-street, Calcutta, India.
Moore, Miss Esther M., 4, Bath-road, Bedford-park, Chiswick, W.
Noble, Mrs. G. J. W., 47, South-street, Park-lane, W.
Peattie, M. M. A., 35, High-street, Oxford.
Playter, Franklin, 6, Beacon-street, Boston, Massachusetts, U.S.A.
Short, Ernest Angelo, care of Messrs. H. S. King and Co., 9, Pall-mall, S.W.
Smith-Rewse, Colonel Henry Whistler, R.E., C.V.O., Brompton-barracks, Chatham.
West, Chas. A. W., P.O.A. Kafferstadt, Harrismith District, Orange River Colony, South Africa.
Whitehead, Ernest William, Twyneham, Queen's-road, Wimbledon.

The following candidates were ballotted for and duly elected members of the Society:—

Cole, Dr. J. W. E., Mwomboshi River, North-eastern Rhodesia, South Africa.
Hall, William Henry, Statistical Department, Sydney, New South Wales, Australia.
Hawdon, Joseph William, 16, Windsor-road, Denmark-hill, S.E.
Kiralfy, Imre, Tower-house, Cromwell-road, S.W.
Longden, Henry, 447, Oxford-street, W.
Meintjes, Laurens Schmitz, African Farms, Ltd., Maribogo Station, British Bechuanaland, South Africa.
Moore, James, 17, Donegall-place, Belfast, and The Finaghy, Balmoral, Belfast.
Newcomen, A. Gleadowe, Messrs. Cooper, Allen and Co., Cawnpore, India, and Messrs. Allen Bros. and Co., 14, Devonshire-square, E.C.
Parker, Walter Edward, A.M., 217, Haverhill-street, Lawrence, Massachusetts, U.S.A.
Tilley, James Walter, F.C.S., 95A, Southwark-street, S.E.
Weeks, Rufus Wells, "Devonbrink," Tarrytown, New York, U.S.A.

The paper read was—

THE NATIVE RACES OF THE UNKNOWN HEART OF CENTRAL AFRICA.

By VISCOUNT MOUNTMORRES.

I take it for granted that everyone present is aware roughly of the geography of Central Africa, that is to say, the course of the two main rivers which traverse it, the Congo and its large northern tributary, the Ubangi. The course I followed in my recent journey was that I entered on the west coast side, went up the Congo as far as its junction with the Ubangi, then followed the Ubangi north up to the fifth parallel of latitude, and then made my way back overland by a semicircle down to the Congo again as far as Stanley Falls. From there I struck out east across to the Uganda border, and came back down the Aruwimi and the Ituri to the Congo again, crossed it, and came back in a direct line along the length of the equator. During this journey I traversed one part at least that no

other white man had crossed, the country between the Ubangi and the Ituri, and in several parts I was the only man, other than the officials of the French or Belgian Governments, that had visited them. I came across races which astounded me with the very high degree of civilisation and development which they had attained to. Many of these races have a civilisation which is wholly and absolutely indigenous; they have learned nothing from the white man, because they have not as yet been brought in contact with him and, so far as is known historically, there has been no Arab influence brought to bear on them in the past. The people met with in the lower and middle Congo are fairly well known to every student of ethnology in this country. I think the only race of interest that I met with on my journey up-country was where I touched at Irebu, and made a journey round Lac Tumba, a large lake lying to the east of the point where the Congo runs nearly due north. There I found for the first time members of that vast tribe the Mongo, who furnish the principal inhabitants of the great equatorial forests. As is almost invariably the case, one finds that the forest dwellers are a low and less-developed type than the inhabitants of the plains and mountains which surround the forest, the fact being that in the course of time the weaker races have all been driven into the shelter of the forest by the sturdier races who have taken the better lands outside. And so you find that on the extreme north, lying between Lake Chad and the Ubangi, there is a sturdy, well-developed, virile race, whilst in the forest there are these undeveloped, backward people; and south of the forest, in the Kasai region and immediately north of Rhodesia, there is a sturdy, energetic, well-developed and comparatively civilised people. A curious thing is that these people to the north and to the south of the great equatorial forest have many traits in common. There is a close resemblance, for instance, between the Banza and Banziri people to the extreme north and the Kasai tribes to the extreme south, and the only explanation one can think of is that probably at some time there was a great movement of the Bantu people from the north, who, to all intents and purposes, completely surrounded the forest, when spreading out eastwards they struck the point where the Congo makes its extreme curve to the north; they avoided the forest, followed the course of the Congo round to the east, and came to the south, driving the original inhabitants into the security and shelter of the forest. It is of these more highly-developed races that I am going to speak, but just to give you an idea of what the forest-dwellers are like, and the way in which they live, I will begin by describing a Congo village.

The slide gives you a very typical scene in a Congo village. The huts, as a rule, are built in a continuons line along so-called streets, really large clearings. Instead of having any definite plantations, as a rule the bananas and plantains and even the tubers are set in the middle of these streets. The people themselves are not over clean, which is a remarkable thing to find among people who, on the whole, are remarkable for their cleanliness. Most of the natives of Central Africa are exceptionally cleanly in their habits and careful of their personal appearance. The Congo people, on the other hand, are on the whole an indolent race, and take very little care of their personal appearance; but every now and then an energetic chief takes the trouble to improve his village, and that was the case at Mwangi. The slide just shown was an old part of the village, unimproved, as it existed certainly for almost countless ages; in the other part, where this present energetic chief has set to work to rebuild it, you see quite a neat, clean row of well-constructed huts, each of which is provided with a little sliding door, and able to accommodate one person. As a rule in these villages the husband, the head of the family, lives in a hut at the end of the street, each of his wives having a hut to herself, the next hut to it containing her waiting woman or slave. In the photograph the occupants of a group of huts are seen sitting outside, as they do almost all day long, sunning themselves, and waiting for Nature to supply them with their few and scanty needs.

In this slide you have another view of the way in which the women sit all day long doing nothing practically. All they have to do is to wait for the bananas which they plant to grow up and ripen, and then pick them off and eat them. Beyond their food, and the necessity of building themselves shelter against the rainy season, the natives have practically no needs to satisfy, as a bountiful Nature supplies them with everything.

The next slide shows you the chief himself in a gathering in front of the hut I occupied. This is Mwangi, who has taken to European dress. He comes very frequently into

Trebu, the white station, and nothing pleases him so much as the gift of a pair of sand shoes, or an old white coat. On this occasion I think he had on three different coats, one over the other. Another white man who was staying there gave him one, I gave him one, and he had one to start with, and it was amusing to see him going out with these coats flapping in the breeze as he walked along.

The next slide is a photograph of another native who is chief of a small village abutting on the other; he is known to the white men all round that district by the name of "Britannia," due to the fact that he goes about in a costume closely resembling that of the lady who sits on the back of the British penny. He invariably carries a spear, and evidently has been told of the lady on the back of a penny, or has had a penny shown him, for whenever he comes to rest he always assumes the attitude of Britannia.

Leaving Trebu, I went, as I have said, up the Ubangi, and I found at one of the white stations there one of the largest cemeteries for natives that I have seen in Africa. All the natives in Africa have different methods of burial, some of which are highly insanitary, consisting very often of throwing the bodies into the river. A great deal has been done in organising and persuading the natives to bury their dead in regular burial grounds, and the natives take considerable care of their burial grounds in some parts. In this particular case there was a large number of graves, all of which were covered with the personal appliances that were necessary during the life of the native who was buried there. There were cooking utensils, lengths of cloth, in many cases a large tin trunk, and various other objects distributed on the graves. Each one of these objects, whatever its nature, was damaged beyond repair, the natives saying the reason for this being to prevent the evil spirits from coming and making use of them, but I rather fancy it is to prevent the less orderly of their fellow-tribesmen from coming and stealing them and making use of them. At any rate, it is the invariable custom to damage the articles that are put on the graves. In other parts of Central Africa I came across graves on which it was the habit for every passer-by to contribute some article, usually of food. Whenever a white man went past it was the custom for him to throw a cigarette or a cigar on the grave, and one could tell from the number of such cigars and cigarettes exactly how many white men had been along that route. The graves in this part were beautifully kept up; everything deposited on them was left untouched, and there was no need to damage the things. All the little cooking utensils were kept at one end, the food supply at the other, and when the food decayed it was swept away as having been consumed by the spirit of the dead man on his journey to the other world.

On the Lower Ubangi there is an extraordinary mixture of races, and one's task in trying to unravel their exact relationship is made all the more difficult by the fact that there is no very general agreement as to their names. You find tribes entirely different called by the same names by different authorities. For instance, the tribe of which you see a picture is the Sango tribe, which are called by other writers the Dongo tribe, while the people who are called the Dongo by one set of writers are called the Budja tribe by another set of writers. So you find, if you try to gain any information from works on these races, it is practically impossible to do so, and all one can do is to start on one's own and distinguish the people by the traits found existing amongst them. Whatever we like to call this race I should say probably that it is an offshoot of the great Bangala race which inhabit the northern bank of the Congo, and has penetrated up to the Ubangi. My reason for believing that is, first of all, the character of the buildings. They build their villages round little squares, very neatly, and without any ornamentation—a perfectly simple group of huts round a little square, which opens into the next by a straight alley-way, so that you can look down the central lane; and, as you walk along it, off each side open a series of little court-yards with huts all round them. Another thing is the shape of their heads. They are all very wide-headed people and very finely built, except their legs. They are all rather weedy in the legs, but they have wide shoulders, obviously bespeaking a nation of paddlers in the habit of living in canoes and paddling a great deal. Another thing is that you get for the first time in this people what is generally called the Sango tattooage.

The next slide is a photograph of the chief of the village of Imesse, a large village close to the white post of which you saw the cemetery just now. You will see here that the tattooage of the Sango people consists of three little lumps raised on the forehead. On the lower Ubangi only one little nob is raised on the forehead just

between the eyes. As you get farther up you get to three nobs, and with those three nobs all kinds of additions, according to the sub-tribes to which the people belong.

The next slide shows you another feature in reference to the buildings of the peoples of Imesse. One reason why I think this tribe is closely attached to the Bangala tribe is that their huts are all palm thatched. There is a great division between the palm thatchers and the grass thatchers. Of course the explanation is one of locality in the first instance, but you will find that the palm thatchers in a neighbourhood of grass land still go to great trouble to thatch their huts with palm leaves, although they have plenty of grass round them; and *vice-versá*, the grass thatchers, when they live in the forests or in a thick scrub, will go to immense distances to fetch grass to thatch their huts. So that the distinction, although originally undoubtedly one of the facilities of the localities in which the natives found themselves, is no longer so, but rather a tribal distinction. Again, the Bangala people almost invariably, after the thatching of their hut is complete, in order to prevent its being carried away by the tremendous tornadoes on the Equator in the immediate district in which they live, have been in the habit, for many generations probably, of covering their roofs with little transverse bars which hold the grass in place. That is a thing one looks out for as a characteristic of these tribes. You find in a district where tornadoes are not severe that this peculiarity of covering the roofs with transverse pieces of stick, held in place by the weight of enormous full-length trees, still prevails, although probably there is no actual need for it.

There are also the typical Bangala chairs made out of trees which are cut and stuck in the ground, and which have certain very definite and regular shapes. A particular shaped fork is sought after, and you will find in one village perhaps dozens of that particular shaped fork until you begin to wonder how on earth so many similar forks could have been found in the neighbourhood. In another village you will find another pattern prevailing. The type shown in the slide is set up on end, with a seat, as it were, for the person to sit in. That is the Bangala pattern. When you get a little further up it is merely a back rest; the occupant of the chair sits on the ground, and leans on the back rest, with two forks to support his arms. The next slide shows you a little advance on the last, in that you have the typical dress of the Bangala, the ballet skirt as it is called. It is quite true that it has spread from the Bangala people to many other tribes, especially to those just a little further north of these people, but the people round Imisse invariably wear them, whereas in other parts it is only a very smart lady who has advanced to this degree. She has copied from her neighbours, much as we in England copy from France. The native women are almost invariably devoted with an extreme attachment to their children, and whilst many of them will go without bangles and armlets you will invariably find that their children are laden with every form of crude and barbaric ornament that they can possibly possess.

In the photograph you will see that the woman has no ornaments, whilst the child is absolutely laden with them; his little black curly hair is plaited into tiny plaits and ornamented with pieces of ivory, boar's teeth, and beads, in fact anything that will decorate and ornament it. I took about four photographs of this child in order to try and get a view of its face, because it was one of the very few really pretty native children I saw; but every time I was going to take the photograph and asked the child to keep still, in a natural fright it turned away and snuggled against its mother, so that I could not obtain a full-faced view. The next photograph shows you a palm-thatched house, and we can conclude from that that it is inhabited by some near relationships to the people we last saw. It has not, however, the transverse bars. You find that suddenly you come across a people amongst whom it is the custom for every free woman, as soon as she gets to marriageable age (which out there is about eight or nine years of age), to wear an enormous brass or copper collar round her neck, which weighs many pounds, and which is forged on to her neck. Quite a ceremony is performed when this collar is forged on, and it can only be removed by removing the head of the wearer first. The collars are worn practically from childhood until death, and as they are never removed day or night, the wearers sleep in a pillow hollowed out to support the head, leaving the collar free. Very often it causes large sores and abscesses on the shoulders, but the people never think of discarding the collar. It is a very marked characteristic of these people; but you find immediately after passing the group of villages in which this photograph

was taken this particular characteristic disappears again as suddenly as it appears. This is really a Dongo village which has pushed its way down to the river bank, although the majority of the Dongos are agricultural people who inhabit the interior. This particular village, which is called Dongo —very often villages are called by the tribal name—is one of the largest native conglomerations that I came across. It has a population that cannot be less than 7,000. During two days I took the utmost pains to try and verify exactly its population by various means. I counted the huts, the wives, the children who were too young to work, and used various other means, and I came to the conclusion that 7,000 was a good deal below the actual figure—I think probably there must have been close on 10,000 in this one town of Dongo.

In the next photograph you can see more plainly that these are distinctly palm-thatched roofs. The women are in the typical dress; they still wear the Bangala ballet skirt, but this woman has added a little apron of string, and wears the big characteristic collar, which is a kind of dog collar, open in front, the edges being rolled immediately under the chin to hold the head up, and all round it, beaten on to it, is a supporting rib which prevents it being opened once it has been forged on. It gives the woman a peculiarly graceful and dignified carriage, but it is certainly very uncomfortable.

The last photograph shows you the chief's daughter. Dongo himself, when I visited the town, was absent, hunting in the interior, and his daughter entertained us and showed us about. Another free woman of the place is also to be seen, and you will notice the enormous quantities of bangles that the women wear. They wear a number of brass rings, carefully graduated, the smallest of them weighing probably not less than 1¼ lbs., and the largest from 2½ lbs. to 3 lbs. You can imagine, therefore, the weight they have to carry about on their arms, and the intrinsic value of these rings, for which the brass has been imported at some time from white men. It has made its way slowly up the river, passing probably through hundreds and hundreds of hands before it reaches its final destination. In that part of the world transport is the principal item of cost, and the intrinsic value of these brass bangles to the native is enormous. I asked one woman how many brass rods she calculated went to make the collar she was wearing and she told me—(and I think she was probably right; one can verify it fairly accurately by knowing roughly the weight of the collar)—about 6,000 rods, which represented a value in English money of a little under £20 for that one collar. That means to say that out there to the native woman it was a very large fortune indeed; in fact the womenkind carry their fortune on their backs undoubtedly. The fortune of the men is the number of their wives. When a man gets rich he buys more wives; when he gets poor he sells them again.

The next slide shows some of the warriors of the village of Dongo. One peculiarity of Dongo, which makes it almost certain that it belongs to the tribe which is generally recognised by that name, is this, that it is very exactly divided into three distinct wards, the inhabitants being separated by a kind of caste distinction. I believe that the Dongo are the only people amongst whom this caste distinction exists in Central Africa. Everywhere the forging of metals is either an object of veneration or an object of disgust and loathing; it either represents the highest type of labour in a village or the lowest. That is the only other instance in Central Africa of anything approaching to caste; but in Dongo, and in all Dongo villages, the villages are distinctly divided into three parts. One part represents the labourers—in this case, being a river village, the fishing people, who devote themselves to providing nourishment for themselves and the villagers, and for trading purposes with the interior. The second section are the manufacturers, the workers in metal, and the makers of cloth and pottery, in fact, all the textile manufactures of native life. The third section are the warriors. The men are armed with enormously long spears, about 9 feet 6 inches or 10 feet in length, and they are very skilful in throwing them. Their other arms consist of large-handled knives, in ornamental scabbards, bound with copper wire. They are protected not only by their shield, but by a strange kind of cuirass made out of buffalo hide. It is slung on the shoulders and protects their back and spear arm, the right, so that in that way they are practically safeguarded against attack by native weapons. The Dongo are a people who have reached a considerable degree of development, both in arts and manufactures.

The next picture shows a group of natives who were waiting our arrival at the village of Dongo. At first we were rather doubtful of

them, because we were informed that the only white man who had, in recent times, visited the village, a missionary, had been eaten, and had not since been replaced. We felt a little timid, but they extended a most hearty and cheery welcome to us. The day I arrived there, a white man, who had marched across from the interior, an official of the Belgium Government, arrived in the village also, and before I left he was installed there as a representative of the State authority, and was on the most excellent terms with the chief's daughter, the chief being absent, but I have no doubt that on his return the Dongos would settle down to be law-abiding members of the community. And they ought to be, because their trade is very highly developed. They understand all the ordinary principles of interchange; for instance, the fishermen in this village exchange with the agriculturists in the interior, and the pottery, cloth, and metal work is exchanged for fruit and produce grown at other parts of the river.

As artists they have also advanced very far. The house of the chief is entirely ornamented with carved wood, a kind of ebony, which is not as hard but almost as black, and grows freely in this district. The wood is most highly polished, and ornamented with rude sculpture work and carving. On the front of many of the houses are panels, left plain, on which rough pictures are pencilled with burnt wood. The meaning and purpose of the drawings one could easily understand. How recently these people had been addicted to cannibalism was only too evident on the occasion of my visit, because at every street corner in the village there were one, two, three, or more human skulls half-buried in the ground, each of which represented a cannibal feast. It was their habit, when they had had a particularly cheerful evening in dining off some fattened slave, to half-bury the head, in order that it may recall the pleasant evening they had spent together. Some of these heads were quite newly interred; and I think there is no doubt that if one could arrive quite unexpectedly amongst the Dongo people, one might surprise them, even to this day, in the midst of a cannibal orgy. But, as I say, they are a people who will probably settle down, as many other savage people in this part have, to the ordinary principles of civilisation.

The next photograph shows a village in the transition stage, probably the last of the Dongo villages proper, where you see all the ladies still wear the collar but very few of them the Bangala skirt, which has not got as far as this place. Most of the roofs of the houses are palm thatched, but many of them you will notice are beginning to be grass thatched. It is a transition village, made up, no doubt, of members of different tribes who have left and intermarried. There is no doubt that cannibalism all along this part was very prevalent until quite recent times. One of the most extraordinary things is that almost everywhere I went, even where the white man himself has not been, or where he is little more than a legendary figure, the native is already ashamed of cannibalism, whereas in times past he was openly addicted to it. One old fellow told me that the meat of a white man was much better than the meat of a black man because it has a salt taste. All along the river we were greeted at every stopping place by large crowds, who used to come down to the water's edge to meet and cheer us. If ever we wanted paddlers there was no difficulty in finding them. At some places, for instance near Yakoma, the men were so energetic and keen to do the white man a service that they ran along the bank, leapt into the water, came swimming out to my canoe, and forcibly dispossessed my own paddlers of their paddles, throwing them into the water, and themselves took on the task of paddling; just as in this country the custom still exists in many parts on the return of a bride and bridegroom to unhorse the carriage and drag it along by human power. The idea underlying their action was exactly the same; they wished to show me honour, and the way they did it was to work for me and bring me themselves into their village. Their enthusiasm was very agreeable in its intent, but apt to be rather awkward and productive of unpleasant consequences in its execution, because the chances are that if you have 20 or 30 lusty savages climbing into a canoe and having a hand-to-hand scuffle with the canoe men, if the canoe is not swamped your belongings will get fairly wet.

The next photograph shows one of the groups that met us at the edge of a village belonging to another and quite distinct people, whose name I want you to distinguish from the name of the Zongo, namely, the Sango. You will see at once the difference in the villages. They are not built in squares but in long, perfectly straight lines, each debouching on the river. The people are entirely a riverine people; they live by fishing and paddling, and are not found in the in-

terior. One or two villages that have pushed into the interior are completely hidden in the dense bush, and the paths leading to them are skilfully disguised so that a stranger would not find them. They appear, as they have advanced into the interior, to have got shy and timid, whereas on the river bank, which is their domain, and in which they are in their element, they are nothing of the kind. They build large villages showing to the river, and on the approach of every canoe they come down to greet it, or, no doubt, if it is an enemy, to attack it. They are very far from a timid people when they are on the river bank. You will notice that nearly all the huts have the characteristic thatch I have mentioned; but in some villages it is wholly absent. As a rule you can tell a Sango the minute you see him by the three bumps, of which we saw the first signs in the Bangala people lower down the river. These villages are of enormous length but of no great depth, the object of each member of the population of a village being to be as near the river and the fishing as he possibly can be. These villages consequently extend along the river's edge sometimes for a matter of miles.

The next photograph shows you in detail the method of constructing the villages. It is the habit of these people never to move their villages bodily. When the ground on which they can grow crops is used up, or when the fishing has gone away from them, or when they want to improve their village they let one end fall into ruins and go on building at the other end. Before you come to a Sango village you come to a large clear space, with ruins of old huts in it, while at the other end the village is continually moved forward, through the bush, and no doubt that accounts in a very large measure for the very healthy condition of the tribe. As a rule the Sango people are fine in physique and exceedingly healthy, with very little disease. Their children especially are amongst the healthiest children that I saw. Most of the children of Central African races are subject to rickets; in fact, a large majority of them would do as examples, in a work on pathology, of typical cases of rickets. There is no doubt that the healthiness of the Sango people and their children is very largely due to the superior sanitation of their villages, owing to this constant process of moving which goes on amongst them.

The next slide shows you the way in which they build the huts like long sheds. The whole street is built from one end to the other; stakes are driven into the ground, bamboos or palm branches are stretched across to form the roofs, and transverse pieces are put on which are thatched with grass. The work requires a considerable amount of skill. The villages, which are laid out absolutely symmetrically, are exceedingly strong and well built, and the pace at which they are constructed is simply astounding. In this part of the country I spent two days in the interior, and stayed about a couple of days in the village itself, so that altogether I was there four or five days. From the time that I first saw the place, to when I left, the people had entirely constructed three of these long streets, that is to say, six rows of long sheds ready for thatching. Every joint in the huts is tied with little pieces of vine creeper, so that the detailed work is enormous, and yet they do it with a rapidity that could not be equalled by the ordinary European. It means that this particular form of labour has reached a very high stage of development.

Now we come, quite suddenly again, to an entirely different people. Here we break on the Upper Ubangi. The usual distinction between the Upper and Lower Ubangi is between the span-roofed huts and the beehive or conical huts, and here you have the beehive shape. These two photographs were taken within a day's paddling of one another; they show practically one set of villages running right up to the other set, and yet the distinction is complete. You never see a span-roofed hut in one of these villages, or one of the beehive huts in one of the span-roofed villages. You can therefore be absolutely certain that you have come to an entirely different and distinct people. That is borne out when you see the people themselves, because they are a wholly different race in every respect. In the first place, the type of countenance is different. You will notice that they are not, on the whole, bad-looking; they are nothing like as coarse-featured, for instance, as the Bangala, or Sango, or Dongo; they are a much higher type of race altogether, and much finer built, so far as their lower limbs are concerned. The feature that distinguishes them above all in their characteristics is that they are the most artistic of all races in Central Africa. They are the Banziri. Every man amongst them has his hair plaited into tiny plaits, with the smallest beads that he can obtain. The beads travel right across Africa

from tribe to tribe, from the nearest trading station of a white man. They plait these beads as a rule, red and blue, in a very artistic fashion into the hair, forming a complete cap, very often with long pieces hanging over the ears, and almost always with two little tablets hanging down in front. Nearly every man in the race does that with his hair. Then they have an extraordinary love for colour. Most of the races, especially those along the Ubangi, prefer dark maroon red or very dark blue. If you have a large selection of cloth, as you must have when you are travelling, you will find there is a great run on the dark reds and dark blues until you come amongst the Banziri, and then all the pieces which you had been despairing of being able to use at all, the light blues and greens and all the other gaudy colours are suddenly in great demand. Nothing pleases a woman so much as to have a long length of vivid red cloth to wrap round her body. One of the men shown in the photograph is probably a foreigner to the race, but he was dressed from head to foot in red. He was living amongst them, and no doubt had married into them. He had worked on a steamer on the lower river, and had earned enough money to buy himself a pair of pantaloons and a jersey, both of which were a vivid red, while his head was covered with a red covering made out of ordinary Turkey twill. The sight of this man dressed in red, with the women dressed in green, was extraordinary in the extreme, especially when one had been in a country where one had not seen a speck of bright colour before. The villages of the Banziri differ again in another respect from every village we had seen up to this point, viz., that there is no attempt at building them along streets—there is no mathematical symmetry about them at all. They are scattered about in the plantation, and very often, as you see in the photograph, they are almost hidden and smothered with trees. There are wide spaces between them, and very well-kept pretty little paths, trodden down by travel. Along both sides of the paths the grass grows freely, and the general effect is far more picturesque and attractive than those of the races that build long, straight streets. The same characteristic is true of the other kind of huts we came across—the conical huts. We see no more of the Banziri type for the time, but pass from the beehive hut to the conical hut. The conical hut varies enormously, and in its variations we distinguish the different tribes. For instance, there is the hut which is built straight from the ground; there is no attempt at a wall; it is all roof. The huts also vary very much in their height. But whereas in many parts there are no walls, in other parts there is a small wall and the roof springs from that. In others, again, the floor of the hut is raised to a considerable extent above the surrounding ground, and the walls are carried up above that again. So that there are half-a-dozen different varieties of these conical huts, each denoting a different tribe, but the conical hut as a whole denotes always the great Banza people. The Banza people are one of the largest groups in this part of Africa. The density of the population here is absolutely appalling. One passes all day long through a series of villages along the river banks. The villages are no longer the shallow villages of the Sango, but extend away into the interior as far as the eye can see. I went many days' march into the interior, and for the whole way one passes through a village, then the plantation, a little bit of open space, and, perhaps, after an hour's walk, there is another plantation and another big village, and so you go on, one village succeeding another in practically unbroken succession. Between Mokoangai and Banzyville, to all intents and purposes, it is one vast town the whole way along the shores of the river. These people live entirely on fish and on their crops. They have no chance of getting game, because it has been driven by this enormous population to such a distance from them. Altogether, unlike the Banziri lower down the river, who are a very sporting people, these people take no interest whatever in hunting, and are practically a non-hunting people. This is the result of their being town dwellers. Another result of dwelling in these large conglomerations is that all the industries have reached a high pitch of development, their iron, copper, and metal working more particularly. I saw some beautiful work being made in the forges in nearly all these villages. I watched and saw how it was made; and the skill that is displayed by the natives in the manufacture of elaborately chased and fretted knives, in binding handles in an ornamental fashion, and inlaying them with lizard skins, and generally turning out objects of beauty, is extraordinary. Their only appliances are, as a rule, a large stone for an anvil, and a smaller stone for a hammer, which is often enclosed in a creeper handle. Such a thing as a cold chisel in the way of a cutting instrument

is absolutely unknown, and the only cutting instrument they use is practically a soft iron instrument to cut the red-hot iron and fret it into patterns. You can imagine the time it would take to manufacture a knife in this way by anyone who is not highly skilled. While in one village which I visited, the chief, in order to do me honour, and seeing I was interested in the subject, ordered all his forges to start making patterns of spears and knives. I stayed with him him two nights and the intermediate day, and perhaps half the next day, and during that time the forges were going night and day, so the noise in the town was terrific. When I came to leave he called all the metal workers together, and they came bringing with them the result of their labours. I cannot guarantee that all the spears and knives were made during the time I was there, but they were presented to me as having been made during that time, and the total was 52 knives with large handles all beautifully ornamented, and 36 spears. Everyone of the spears was bound with copper wire, and inlaid with lizard skin at intervals, and the handles was beautifully carved. Even supposing that onlf half of them were made while I was there, it shows that these people have reached a degree of skill in metal working which I do not think could be equalled by white people unused to their primitive appliances. It is just the same in building; the skill they display and the pace at which they build their houses are simply extraordinary.

The next photograph shows we have now got into the wall stage. This is the beginning of the tribe of Baya, a large sub-division of the Banza people. You will notice a net hanging out to dry. These people along the river are most skilful in the manufacture of all appliances connected with the fishing industry. The fish nets and fish traps have reached an extraordinary perfection. The nets which are made on the lower Ubangi by less developed people are principally made out of creepers, the bark and tendrils of trees. A large square is made on a frame, and the tendrils are stretched backwards and forwards to form rude meshes. Some of them are knotted at the corners, while others, instead of being knotted are interlaced like a child's kindergarten map. But amongst these Banza the nets are almost wholly made of string, some of it plaited, some of it twisted; and some of the rope they make I should think must be as good as any rope made in the world. It is close twisted and very strong, and is made out of the grass which abounds in the neighbourhood. The nets are made of string, and all the meshes are knotted in very much the same way as an ordinary European net would be made. In addition to these nets, they use traps of all kinds, including a trap that is exactly similar in pattern to our lobster pot or eel trap. They are made in exactly the same way, and, from their appearance, might have been imported from Europe, although we know that is quite impossible in this locality. Another ingenious arrangement is the fishing platform or weir, which is constructed to support the lobster pot traps. On each side of some rapids two big poles are put up, connected by a cross pole; suspended from this by enormous creepers are the fish pots, which hang in the rapids. The whole of the structure can be tilted by pushing on the extreme end, so that the bar is tilted, and all the fish pots are swung ashore. When they have been emptied they are swung back again. It is one of the most ingenious contrivances I ever saw. Another arrangement is a weir, very much on the same principle as the weirs we use in this country, with rudely constructed water gates, which can be lifted up. A platform is built across the top on which a man can walk; he lets a tremendous flow of water into a particular channel, which is completely surrounded by a net; all the fish coming down from above are forced into the channel and pass into the net. This weir arrangement is, I believe, one of the most successful traps for catching fish, but it is only applicable to waters that are not used for the purposes of transport, and the consequence is it is only in the smaller streams it can be used.

The next slide shows a group of Baya people coming down to the water. You will notice that, for the most part, they are tattooed, but they have no distinctive tribal tattooage. One finds amongst the Banza people, as a whole, that there is a tribal tattooage, but amongst the Baya, which is simply a sub-division of them, the tattooage is almost entirely absent. At the most, it consists simply of a bit of the Banza tattooage; it is a large nob, which falls down in front from the middle of the forehead, a small nob above it, and a series of four nobs across the eye-brows. One or two of them, more particularly the women, go in for tattooing the shoulders. This tattooing is remarkable for the beauty of the designs at

which they have arrived. Many of them resemble very closely conventional designs taught in art schools in this country, and amongst others I came across was the regular *fleur de lis* of France enclosed in an empire frame-work. How it got there I do not know; it may have been brought in some cutting of a paper which somehow reached them, but it was so European that I do not believe it could have originated in the locality. It was exactly the same design as on the woman's arm in "The Three Musketeers." The tattooing is effected in the following manner:—The skin is cut, turned back and filled with a fibre extracted from between the bark and the main wood of a particular tree, which is pounded and dried; it is put into the wound, and the wound is then sown up over it. In course of time it suppurates, a little abcess forms, the flesh begins to hang down, and this wadding from inside forces its way out little by little. In one village at which I stopped on my way up-river, the medicine man, the tatooer, was then paying his annual or semi-annual visit, and all the boys in the place were undergoing tatooage. You can understand that the noise most of them made over it was considerable, though a large number of them bore the operation with extraordinary fortitude. This man, with an ordinary native knife, would cut three great gashes in the forehead; he would then put in the wadding, and draw the flesh over it, and with two bits of tendrils of creepers tie up the wound. It was then left alone; I suppose the patients would probably pass many weeks with these terrible festering sores on the face. In some places the natives are simply tattooed all over; the whole of the face and the body is one mass of tattooage. In this particular part the tattooage is strangely absent.

The next photograph shows the capital, Baya, itself. It is called a village, but it would be more accurate to call it a town divided into large wards. Over the whole town Baya, the chief, himself presides, a man who has been in his time much in contact with the white people, both in the French and Belgian colonies. He dresses in quite a Europeanised fashion and has introduced into his village many European methods. He is about two days' march from the nearest white post, and the town is extraordinary for the cleanliness that prevails there. You have amongst the whole of the Baya people another burying habit. When a man dies, if he is a big chief he is buried in his hut; if he is a chief of less importance, immediately outside the door of his hut; and in either of these two cases the hut is given up to the use of the dead man. But in the case of the ordinary private citizen of the village, he is buried some little distance in front of his hut. A regular family tomb is established, and little shelters are erected. A forked stick runs up at the corner on which are hung the various trophies of the chase, which are very highly prized because this is not a hunting or sporting people. The consequence is that if a man has killed any animals he keeps the trophies, just as a white man would keep them. Very often he decorates the top of his hut with them; for instance, if the native has shot an antelope with horns, he keeps them in front of his house, as you see in the photograph. When he dies all these things are hung on the branch at the corner of the tomb. Then there is a shelf on which are deposited all the spears, knives, warlike instruments, agricultural implements, and everything of that kind; and below that again are his domestic appliances, the calibashes in which he kept his palm oil, his palm wine and water. His cooking utensils of all kinds are stored there, and the members of his family keep up the tomb with a considerable amount of care. Very rarely a day passes but you will see one of the deceased's widows pottering about it, cleaning it up and setting it in order; in fact, one or other of them will generally devote her whole time to the upkeep of the tomb.

In this town one meets with every style of architecture. The dwelling-houses of the women always remain the same, a low-walled conical hut, but everything else in the village is built in a variety of styles that is puzzling. The photograph shows a house that was built, so I was assured, before the white man came to the nearest white post and before European influence could have been brought to bear upon the natives. It is a mud-built house, with a large wide verandah in front of it.

In all these villages there is not only the dwelling-house, but in front of it a day shelter in which the mankind sit and smoke and talk and generally pass their time. Most of these Baya people are energetic and industrious, but at the same time there is always a great part of the day in which they have nothing particular to do, and then they occupy their shelters. The shelters themselves are most picturesque buildings. You will see plainly

that they are all grass thatched, the one in the photograph having little minarets and spurs at each end. The roofs instead of being built perfectly symmetrically have a kind of waving edge at the two ends. The general effect of this town of Baya is exceedingly pretty.

The next photograph shows you how the influence of civilisation is making itself felt. Baya went and lived in the white post for about a month and watched the brickmakers at work. He came back to his village, and from what he had seen he started his people to make bricks, and to build a brick house. The photograph shows an enormous guest house in which he receives his visitors in quite ceremonious state, and the walls are built entirely of brick. Then he thought he would be more ambitious. He heard that in another white man's post, at the Dutch factory, about a fortnight's travel away, there was a two-storied house. He promptly started to build a two-storied house; but I am sorry to say that when the walls had just got above the first floor level they were so out of the true in some places that the bricks were falling off them as the mortar dried. He will probably never realise his ambition to build a two-storied house, but he was very successful in his first essay at brick building. This is interesting only as showing how quickly these people adapt themselves, because the whole of these people held out for a long time against the white man. In the middle of this village there is a little group, apparently of Banziri people, which I was absolutely unable to account for, living in beehive huts. There was a little strip of plantation in between. These towns are largely made up of groups of villages, completely shut off the one from the other. Two or three minutes' walk from the nearest hut in the Baya village there appears to be a Banziri village. How it came to happen I do not know. They call themselves Bayas, and they are the subjects of the chief Baya, and in every sense politically and socially they are Bayas; but by origin I should think from the type of building they must be Banziris, unless Baya's father, seeing the Banziri hut, resolved to copy their style of architecture, and made this attempt. The difficulty of getting information about anything in the past is very great, because ordinarily the healthy man lives to only 37 or 38 years of age at the most. A man anything over 40 is an old man. The consequence is that by the time a man has grown old enough to remember anything he is dead before he can hand it on as intelligent history, in our meaning of the word. I could not get particulars of anything that happened in the days of Baya's father's boyhood, or whether it was he who introduced the new style or his grandfather. The natives had many stories as to why these huts existed, but there was no reliable information to be obtained, and no two natives told the same story.

The next photograph is a general view of a group of huts showing the extraordinary variety of architecture. It is not a brick house, but another type of mud house. It consists almost entirely of a large verandah, and at the end there is a kind of office where the over-chief of the village, or ward, does his business.

In the next slide another characteristic of the Baya buildings is shown, namely, the beginning of the minarets or curious caps which they put on the top of their conical huts.

Amongst the Gembele, another division of the Banza, these things develop into the most elaborate ornaments, some of them ten or twelve feet in height, enormous structures resembling the pagodas that you see in China. They have a sort of umbrella shape, with antlers hanging from the corners, giving quite a pagoda-like look to the house. The town of Baya having apparently copied the architecture of all the neighbours round about, has copied the pagoda effect in some of the huts.

The next photograph to many of you will be the most interesting view I have shown, because it depicts the degree to which the social organisation of the place has been developed. We have heard a great deal recently about the underfed school children of England, and here is the Baya solution of the difficulty. All the younger children in each ward or group are kept in a crèche. There is a net work all round enclosing the whole thing, so that the children cannot get into any trouble. For the most part, the children are left there; the mothers go in and out, when they are not too busy. When they are occupied in the fields or with their domestic duties, they simply leave their children in this crèche. Another institution in all these villages that go to make up Baya is the maternity home, a similar establishment to this. These two things from a social development point of view are highly interesting, because they show the

sense of the obligation of the community to look after its individuals. The care taken of their children by the Baya people no doubt in a large measure accounts for the enormous density of population in this part. I did not find these maternity homes and crêches in all the villages of the Baya tribe, but in every one of the villages making up the town of Baya as a whole there existed a separate maternity home and a separate crêche for each village.

These photographs show the ornamentation of the huts and the pagoda-like appearance. You will notice three ornaments hanging from the hut, and a pair of antlers on the top. That is the farthest point to which this pagoda arrangement has reached in the town of Baya. The next view shows a general group of huts, indicating more plainly the fringe-work ornamentation of the roofs in many of the shelters. You see here how beautifully the whole town of Baya is kept up, and how clean it is. It is approached by a road that took a good hour to traverse, which is kept as well as any avenue in any of the white stations that I saw.

The next photograph gives you an idea of their stock farming, and shows you their pigeon houses. I could never make out what the object was of setting them up to such an enormous height. In all this part of Africa they keep large numbers of pigeons and fowls in every village, and there are often large flocks of goats. The fowls, but more particularly the pigeons, are kept in extraordinarily elevated abodes. You often see the fowls flying up from roof to roof in order to reach the fowl cot, which stands about ten or twelve feet from the ground. The pigeon houses, of which there are dozens, must be 25 or 30 feet high. I could not find out why they were raised to this extreme height, but it was a common custom of the people in this part to build their dove cots and fowl houses to a considerable height.

The next view shows the houses grouped together, with an evident eye to effect. Whoever did it intended that the town should present a varied and picturesque effect, and succeeded most admirably.

The next photograph shows Baya on a visit to the white man. Perhaps you would like to know the history of my meeting with him. I was laid up very ill in a village, and he came across me and conducted me to the white station. Then I went out and paid him a visit at his capital, about two days' march, and he came back and returned the visit to me in the white station.

He came with an enormous number of his people. Whenever these tribes come in there are always quantities of disputes to be settled, varying from the minutest and most delicate domestic quarrels up to the most complex and elaborate points in intertribal law. You will see that Baya is dressed in a white European suit and cap; he always wears white boots, and dresses in thoroughly European fashion. The photograph shows the Resident delivering judgment on some case. It shows the very high intelligence and adaptability of the Banza, who were the absolute enemies of the white man only seven or eight years ago, and blocked his progress completely in a large part of Central Africa, when you find that nearly every tribe is now on the terms of the utmost friendship with the white man.

The next photograph shows you my tent in the bush, and gives you an idea of the way in which one travels. One travels across a country like Africa, either with a caravan of bearers, who carry everything you possess; or, if you travel by water, you travel in large canoes, of which you require quite a fleet. You can imagine the joy of sitting for thirteen hours in the broiling sun in one of these canoes, with perhaps twenty or thirty natives shouting, dancing, jumping, halloaing as they paddle; there are at least two or three tom-toms in the canoe and several brass jangles and two or three ivory horns all keeping time with the paddlers. This goes on for thirteen hours, during which one is bound to keep almost in the one position, because they do not stop. The native likes to get to his journey's end as quickly as he can, and if you stop him he grumbles and says you are not treating him properly. The only way to keep the natives in good spirits is to allow them to make as much noise as they like, and let them go on paddling from half an hour before sunrise to half an hour after sunset without a break. I am perfectly certain that no white man, however strong, could possibly do the amount of work which these people get through in the course of a day with the willingness and the general air of enthusiasm that these fellows show.

I very much regretted when the time came for me to leave the Ubangi and all these charming people, because one gets a very real affection for them, especially in my case, because during a very severe

illness I was entirely dependent on them. I was very dangerously ill, and whenever I came to myself I saw the black face of a petty village chief, who had taken me out to hunt on the occasion on which I was bowled over by the heat. He very much regretted it, and looked upon it largely as his fault. He stuck to me right through to the end of my trip, and was a most passionately devoted creature. At first I could not speak a word of his language, and he could not speak a word of mine, but whenever I came to he was there. He was never in the way, and if I wanted anything he seemed to divine it. If I wanted to punish that man if he did not behave himself, I had only to put him in another canoe for a couple of hours, and he was then exactly like some dog that one has reproved, which seems to understand the reproval, and be pathetic for the rest of the day, I took poor old Njabili down with me to see the coast towns on my return. He was astounded when he saw even the primitive white towns that existed, such as Boma, which is nothing like a European town. His final remark to me when I said goodbye to him was that he was going back to be one of the greatest chiefs that had ever lived, because he had got enough money to buy five new wives.

DISCUSSION.

The CHAIRMAN, in proposing a vote of thanks to the author for his charming and interesting paper, said that his Lordship's remarks on cannibalism had reminded him of the very early days in New Zealand when cannibalism was supposed to be rife. He questioned very much indeed whether any nation had ever really gone in for cannibalism purely for the love of it. That certainly was not so in New Zealand. The natives had in the far distant past occasionally eaten their captives and the white man, whom they designated as the long pig; but they did not approve of the flesh of the white man at all. Their idea of the cannibalism which they occasionally indulged in was that by eating the flesh of the victim they would inherit his virtues; if they managed to partake of the flesh of a great chief they would inherit some of his spirit, and be imbued with some of his virtues. The tattooing in New Zealand was of a much more complicated and elaborated form than that shown in the author's views; in fact, native tattooing, not very long ago, and even to this day, was a work of art, and in some cases a very beautiful picture. He had been particularly interested with the author's description of the country he had passed through, especially his remarks about Baya and its population, and its crèches and maternity homes, because from the little he had seen of both East and West Africa the great trouble of those countries was the lack of population, and the one thing that kept British settlements in Africa back was that want of population. The country was intensely fertile and wealthy, and if there was only a large population he was sure an enormous trade would be done with this country. He had seen something of the intelligence of the natives and their skill in manufactures as described by the author. In British West Africa he had seen the natives make mud huts, which were called cob huts in Australia and New Zealand, adobe in America, and switch in America. He had seen the natives build such houses in perfectly straight lines, and at right angles, and square up the whole thing just as English workmen would do with a variety of tools. He had seen a lady take a piece of mud or clay, roll it up in her hands, and gradually mould it in an incredibly short space of time into a handsome vase 36 inches high. Without the use of a pottter's wheel the people could work up vases in beautifully symmetrical form and design. He had also seen something of the iron-work of the people. Mr. Bellamy, the Director of Public Works in the colony of Lagos, read a most interesting paper not long ago on the smelting of iron ore in the interior of Lagos, some 200 miles from the coast, where the natives from unknown antiquity had carried out the process of smelting iron. The whole process was described of getting the ore out of the ground, smelting it, puddling it, taking it to the blacksmith's shop, and forging it into agricultural weapons and tools of a more or less primitive nature. He admitted that in regard to native questions he was a little prejudiced, because the only knowledge of the native he possessed had been gained amongst the finest type of natives in the world—New Zealand. He had been intensely struck, however, not only with the intelligence of the natives of East and West Africa, but with their kindliness, good will and attention towards each other, and the general spirit of friendliness which they displayed. In recently looking up the travels of one of the most celebrated travellers, whom he was afraid was too much forgotten in these days of civilisation—Mungo Park—he particularly noticed how that great explorer travelled with almost nothing except the clothes he stood up in and a few strings of beads and brass rods. In the days to come the whole of Africa presented a problem which would be of the greatest importance to the British Empire and to the rest of the civilised world. Somehow or other, Germany, France, the King of the Belgians, and England had virtually annexed the whole of Africa. Portugal had already a large share. He hoped and trusted that English rule in Africa would be for the good of the natives themselves, that we should never forget that the country was their country, that they were the only people who had a right to it, and that our only duty in Africa, either

as Christians or as members of a civilised community, was to do everything possible to promote its prosperity, not to be in too great a hurry and impatient of their ways, but to feel that in introducing European manners and customs amongst them we were endeavouring to spread, not only the true light and doctrines of Christianity, but the great blessings of civilisation; and that we were not there, and would disapprove others being there, simply for the purpose of greed or gain.

The vote of thanks having been carried unanimously, the meeting terminated.

CHICAGO.

In his exhaustive and interesting report upon the trade, commerce, and agriculture of the consular district of Chicago for the year 1904, Mr. Consul Finn (No. 3,349, Annual Series) does much to dispel current misconceptions of Chicago, and to indicate the means by which British manufacturers may retain and increase their trade with it. Chicago has a population of over 2,000,000 inhabitants, of whom some 400,000 are Germans and 300,000 British subjects, or British Americans, that is to say British subjects who have taken out United States naturalisation papers. The growth of the city may be gathered from the fact that the frontage erected in the last four years exceeds 146 miles, costing £30,000,000. Thirty-two railroads run 1,839 trains into the city daily; over 16,000,000 live animals came into the city last year; the grain elevators have a combined capacity of 60,000,000 bushels; the telephone system has 113,000 subscribers, and Chicago is only surpassed in manufacturing by London. It is also a port where in 1904 there were entered and cleared 12,904 vessels, with an aggregate tonnage of 12,746,078 tons. Chicago is increasing rapidly as a factor in financial matters, for it has £121,000,000 deposited in its banks, and is becoming the centre and clearing-house of all the Western country.

Much is said in the newspapers which suggests that Chicago is a wild Western town, and Mr. Finn admits that crime with violence is rampant, principally because of the insufficiency of the police and the absence of check on the carrying of arms. But the other side of the picture is a very striking one. There are few cities where so little drunkenness is seen, and none where the people are more able to provide the necessaries of life without appeal to charity. In 1904, Cook County, in which Chicago lies, with a population of over 2,500,000, had 22,301 inmates in the county hospital, and out of this number only 228 were on the list as suffering from excessive use of intoxicants, while during the same time only 3,049 persons were admitted to the poorhouse, the average number of inmates being 1,160. In relieving people in their houses i Chicago great care is taken not to pauperise them, only 7,650 cases being relieved during the past year from one to twelve times at a cost per family of £2 5s. 10d. a year, that is 10s. 11¾d. per head relieved. The streets of Chicago are dirty, but the city has the best water supply in the world, large parks, and many small breathing spaces, whilst its debt is only £4,000,000, or under £2 per head of the population. It has two universities, which are rapidly proving themselves to be leaders in research and study; it has taken a very decided lead in its treatment and care of juvenile delinquents and other children who come under the care of the State, and every social problem which comes before the public is considered very thoroughly.

The extraordinary prosperity of Chicago is largely due to its marvellous supply, still only very partially developed, of mineral and agricultural wealth, to the low first cost in most parts of the country of its multitudinous railroads, which quote low rates for the producer and thus encourage men to start business, and to the enthusiasm put into all work by the reward of promotion and better pay to the best men in all walks of life. Specialising is now to be found only in the rank and file. The men who wish to rise must have a good general knowledge and must keep up with the times to do their work satisfactorily. In most business houses a very careful record is kept of each man's work, and in many a system of profit-sharing has been instituted, because it has been found that the employers' and *employés'* interests must be identical to obtain success.

Mr. Flinn says that there is a market in Chicago in competition with the domestic and foreign manufacturers for all or any articles of British manufacture with the exception of such things as are made from raw products supplied by the United States. During the last eighteen months inquiries have been made at the Consulate for the names of British firms wishing to export the following:—Bristles and fibres for brushmakers, burlaps, perfumery, toilet articles, drugs, china, crockery and earthenware, chocolate, rulers, ship's wagons, paper of most kinds, cocoanut oil, felt roofing and building paper, pepper, nutmegs, glass ware, electrical and gas glass-ware, electrical sockets and specialties, imitation antique jewellery and plate, shellac, wax and varnish gums, wooden and wax matches and fusees. There is said to be a demand for all these things, and trade in them possible if brought before the public in the manner they are accustomed to. Mr. Finn points out the great number of former British residents scattered through all parts of the country, and thinks that there is no doubt but that British food articles, such as biscuits, pickles, jams, and sauces would find a sale among a people who have been accustomed to and know them, and are now in a position to purchase them. Unfortunately Mr. Finn has to make the usual complaint as to British indifference. The Consulate has, he says, on many occasions asked for names of persons in the United Kingdom wishing to export many different kinds of articles but seldom received a reply.

Much he thinks might be done especially if the British merchant could see his way to adopting some American methods as regards his trade with the United States. One of these is by appointing a resident in business in Chicago as agent on commission, and another by employing some one as sole representative. Business men will find much to interest them in Mr. Finn's advice on these points.

Mr. Finn has some remarks on advertising to which the attention of British manufacturers may be usefully directed. The American, he says, believes in advertising and does it to the utmost. It is impossible for the British manufacturer to hold his own, to say nothing of increasing his trade in America unless he adopts the same system as his rivals. There are many British goods which if advertised in the same manner as the competing American product, would, because of their superiority, soon obtain a hold on the market and give good returns to the advertisers. This trade can be got as is shown by a well-known and well-advertised soap, that has an enormous sale and holds its place notwithstanding the fact that its price is about three times that of its competitors. In America and Canada the methods of obtaining business are alike, and these methods must be used by the British manufacturer, but in so doing there are so many mediums, conditions, and even idiosincrasies of localities to be considered that each case and the best manner of advertising must be considered on its own merits. America is a large continent, and to advertise widely is very expensive when compared with advertising in the United Kingdom, but one district can be taken hold of and then others added as business comes in. British manufacturers will also find that their wares must be brought before the American public through the different papers and magazines read by the buyers, and that advertisements in British trade papers have little or no effect in America, as they are only consulted when something definite is wanted, and for which no substitute is to be found in the pages usually consulted.

Mr. Finn has some interesting remarks upon American trade with Canada. In 1904 the sales to Canada from the United States were 60 per cent. of the total purchases of the former country, while those from the United Kingdom were 24·5 per cent. The trade from the United States has increased by more than 5,000,000 dols. in the last two years, and American manufacturers have, under the present system of doing business, no fear of British competition, notwithstanding the preferential tariff. Should, however, any British manufacturer employ an agent in Chicago, he might make arrangements for him to look after the Canadian trade, and canvass Ontario and the North-West Territories from Chicago, as they can be reached in 24 hours, and the pushing methods and advertising of the Americans are understood there. The American manufacturer is eager, Mr. Finn says, for the Canadian trade, and will, if any change is made to increase the Canadian tariff, open branches in that country for the manufacture of his goods, as has already been done in several cases. Mr. Finn has been told, and apparently accepts the statement, that in the manufacture of most articles a tariff of 10 per cent. makes no difference in the price charged the consumer, and must be saved in the cost of manufacture and distribution, but that when over 25 per cent. is demanded, the price must be raised or the article manufactured in the country. The British manufacturer must not expect anywhere in the near future any sweeping change in the American tariff. The United States is so large, the interests and climate so diverse, that changing the tariff will be a difficult matter, as each section of the country seems to be ready to accept a reduction in those articles which it consumes, but not in those which it produces. "If," says Mr. Finn, "our merchants want a share in this trade, they must conform to the requirements of the country, and if they do so the superiority of their wares will ensure them of a good trade for a considerable time; but the American is turning out better work every day, and will soon come to compete in the better-class trade as the demand for it increases."

BRITISH WHEAT SUPPLY.

In the *Journal* of December 2, 1904 (page 53) statistics were quoted to show not only the great and growing dependence of the United Kingdom upon foreign countries for its wheat supply, but the shifting character of that supply. In 1872 Russia sent us more wheat than any other country, and twice as much as the United States. Neither the United States nor Argentina sent us any. In 1890 the position had been entirely changed. Whilst we got 13,561,000 quarters from the United States, and 4,322,300 quarters from Argentina, Russia sent us only 1,031,700 quarters. Coming down to last year, there was another great shifting of supply. The British East Indies, which in earlier years had not sent us any considerable supply, headed the list with no less than 20,469,100 cwts., Argentina coming next with 18,466,700 cwts., Russia third with 16,827,100 cwts. Australasia, recovering from her long-continued drought, sent us 9,268,400 cwts., and the United States had fallen to the fifth place with 6,541,100 cwts. "It would not be safe," it was said, "to base definite conclusions on the figures of the ten months of the present year (1904), but it may be taken as certain that in future we must look to other countries than the United States for our chief wheat supplies."

The accounts relating to the trade and navigation of the United Kingdom, just issued, show that the trend remains unchanged. The largest imports of wheat continue to come from the five countries named above in the order there given. Taking the month ended April 30th, 1905, and the four months, January-April, 1905, the imports were as follows:—

	Month ended 30th April.	Four months ended 30th April.
	cwts.	cwts.
British East Indies	1,442,700	9,493,100
Argentina........	3,697,400	7,786,700
Russia	1,447,700	7,770,700
Australasia	549,500	2,756,000
United States	554,000	2,037,100

Perhaps the most remarkable fact as shown by these figures is the extent of the Russian exports of wheat. Notwithstanding the continuance of the war she maintains her position as third on the list, and her exports of wheat to this country are practically the same as those of Argentina, whilst last year they were considerably less.

Hardly less remarkable is the diminution of imports from Canada. In the paper to which reference is made above, Messrs. Montagu and Hubert were quoted as saying in "Canada and the Empire," that the Dominion may be in a position within comparatively few years, after supplying all home demands, to furnish Great Britain with all the wheat and flour she requires, and leave a surplus for export to other countries. And, undoubtedly, if even a fourth of the land said to be cultivated in Manitoba and the three provincial territories were under crop with wheat annually, Canada would be able to meet the requirements of the Mother Country several times over. But at present her exports to the Mother Country not only do not increase rapidly, they are falling off; if, that is, the first four months, or the month of April, in the last three years be taken for comparison. The figures are below :—

Month ended 30th April — 1903, 486,779 cwt.; 1904, 242,100 cwt.; 1905, 114,400 cwt. Four months ended 30th April — 1903, 1,857,171 cwt.; 1904, 1,827,200 cwt.; 1905, 773,600 cwt.

In 1904 the decrease, taking the four months, was very light as compared with 1903, but comparing the four months of 1905 with those of 1904 it is nearly 60 per cent.

GENERAL NOTES.

Irrigation in the United Provinces.—In the *Journal* of May 5th, an account was given of a large irrigation scheme for the Punjab, sanctioned by the Indian Government. On April 18th last, it was announced at Simla that the Secretary of State had sanctioned an estimate, amounting to Rs.40,390,000, including indirect charges, for a project for constructing a canal from the Dassan River in the Hamirpur district of the United Provinces. The canal will be 20½ miles long, with two branches, namely, the Jalalpur branch, 28½ miles, and the Mandha branch, 14½ miles, and a system of tributaries whose total length is estimated at 210 miles. It will command some 326,000 acres, and will protect a large tract of country from drought. The project should irrigate 57,000 acres in an ordinary year, and about 73,000 in time of drought. The net revenue anticipated is just over one lakh, equivalent to 2·6 per cent. on the outlay.

Post Office Savings Bank Fund.—A return (108) giving the amount of Consols (including Reduced and New 3 per Cent. Stocks) bought and sold for cash, and the cash paid and received for the same, for each year since the establishment of the Fund, has just been issued. The amount of Consols bought for cash since the Fund was created in 1861 is £147,521,398, and they cost £148,507,530. The amount sold for cash was £18,866,189, so that the excess bought is £128,655,209. The highest price given was in 1897 when £6,349,485 was bought at the price of 112·30, in 1898 £4,370,309 was bought at 111·23, and in 1896 no less than £11,543,121 at 110·27. Only £690,624 was bought in 1903 at 91·57, and £50,000 in 1904 at 87·97. The highest price got when selling was in 1887 when £41,947 was sold at 102·5, the lowest in 1904 when £90,000 was sold at 88·38. Taking the whole of the purchases the average price was 100·67, and taking the whole of the sales the average price was 95·86.

German Interests in Venezuela.—German papers claim that about one million sterling of German capital is invested in real estate in Venezuela, and that the bulk of the foreign trade of the Republic is transacted by Germans, of whom about 2,000 reside in the country. Forty large German firms are engaged in trade there. In Caracas they have their own schools, clubs, and societies, and a newspaper published in German. The further claim is made that the Germans have built the railways, and that the manufacturing establishments in the Republic have been organised and are carried on by Germans.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock :—

May 17.—"The Use of Wood Pulp for Paper Making." By S. Charles Phillips, M.S.C.I. Lord Strathcona and Mount Royal, G.C.M.G., will preside.

May 24.—"Modern Lightning Conductors." By Killingworth Hedges, M.Inst.C.E., Hon. Sec. to the Lightning Research Committee. J. Gavey, C.B., Engineer-in-Chief to the Post Office, will preside.

Indian Section.

Thursday, at 4.30 o'clock :—

May 18.—"Plague in India." By Charles Creighton, M.D. Sir Dennis Fitzpatrick, K.C.S.I., will preside.

Colonial Section.

Tuesday, at 4.30 o'clock :—

May 23.—"The Cape to Cairo Railway." By Sir Charles H. T. Metcalfe, Bart., M.Inst.C.E. The Duke of Marlborough, K.G., will preside.

Applied Art Section.

Tuesday, at 8 o'clock :—

May 16, 8 p.m.—"Excavation of the Oldest Temple at Thebes." By H. R. H. Hall, M.A. Reginald Hughes, D.C.L., will preside.

Cantor Lectures.

Monday evenings, at 8 o'clock :—

Henry Willock Ravenshaw, Assoc. M.Inst.C.E., Mem.Fed.Inst.Min.Eng., "The Uses of Electricity in Mines." Two Lectures.

Lecture I.—May 15.—*Application of Electricity and Character of Load.* — Winding—Haulage—Pumping—Coal cutting—Other uses underground—Surface requirements—Generating stations—Cables and distribution — Lighting — Signals — Telephones—Shot firing.

Lecture II.—May 22.—Alternating and direct currents — Precautions — Enclosed motors — Home Office rules—Costs—Typical and historical plants described.

The lectures will be illustrated by lantern slides.

MEETINGS FOR THE ENSUING WEEK.

Monday, May 15...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Mr. H. W. Ravenshaw, "The Uses of Electricity in Mines." (Lecture I.)

Surveyors, 12, Great George-street, S.W., 8 p.m. Mr. J. D. Wallis, "The Licensing Act, 1904: with Special Reference to the Question of Compensation and Monopoly Value."

Geographical, University of London, Burlington-gardens, W., 8½ p.m. Capt. C. H. Ryder, "A Survey Expedition to the Sources of the Brahmaputra and the Sutlej."

British Architects, 9, Conduit-street, W., 8 p.m. Papers on "Sculpture and Architecture."

Camera Club, Charing-cross-road, W.C, 8½ p.m. Mr. J. H. Knight, "Motor Cars."

Medical, 11, Chandos-street, W., 8½ p.m. Annual Oration.

Victoria Institute, 8, Adelphi-terrace, W.C., 4½ p.m. Rev. H. G. Griswold, "The Messiah of Quadian."

Tuesday, May 16...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Applied Art Section.) Mr. H. R. Hall, "Excavation of the Oldes Temple at Thebes."

Royal Institution, Albemarle-street, W., 5 p.m. Prof. L. C. Miall, "The Study of Extinct Animals." (Lecture III.)

Alpine Club, 23, Savile-row, W., 8½ p.m.

Statistical, 9, Adelphi-terrace, W.C., 5 p.m. Mr. Leonard Waru, "The Effect, as shown by Statistics, of British Statutory Regulations Directed to the Improvement of the Hygienic Conditions of Industrial Occupations." (Howard Medal Prize Essay.)

Pathological, 20, Hanover-square, W., 8½ p.m. Annual Meeting.

Photographic, 66, Russell-square, W.C., 8 p.m. Mr. F. J. Mortimer, "Marine Photography."

Zoological, 3, Hanover-square, W., 8½ p.m.

United Service Institution, Whitehall, S.W., 3 p.m. Col. H. De la P. Gough, "The Stragetical Employment of Cavalry."

Wednesday, May 17...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Charles Phillips, "The use of Wood Pulp for Paper Making."

Meteorological, 70, Victoria street, S.W., 4½ p.m. 1. Mr. Richard Strachan, "Measurement of Evaporation." 2. Dr. John Ball, "Logarithmic Slide-Rule for Reducing Readings of the Barometer to Sea-level."

Chemical, Burlington-house, W., 5½ p.m. 1. Mr. W. J. Sell, "The chlorination of methyl derivatives of pyridine. Part I.; 2—methyl pyridine." 2. Prof. W. N. Hartley, "The absorption spectra of uric acid, murexide and the ureides in relation to colour and to their chemical structure." 3. Mr. H. J. H. Fenton, "Further studies on dihydroxymaleic acid." 4. Messrs. W. A. Bone and H. L. Smith, "The thermal decomposition of formaldehyde and acetaldehyde." 5. Messrs. D. L. Chapman and A. Holt, Jun., "The synthesis of formaldehyde." 6. Messrs. K. J. P. Orton, J. E. Coates, and (in part) F. Burdett, "The influence of light on diazo reactions." (Preliminary notice.)

British Archæological Association, 32, Sackville-street, W., 8 p.m.

Microscopical, 20, Hanover-square, W., 8 p.m. 1. Mr. D. D. Jackson, "The Movements of Diatoms and other Microscopic Plants." 2. Exhibition of Slides of the Oribatidæ.

Botanic, Inner Circle, Regent's-park, N.W., 2 p.m. Exhibition of Plants and Flowers.

Pharmaceutical, 17, Bloomsbury-square, W.C., 8 p.m. Annual Meeting.

Thursday, May 18...SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Indian Section.) Dr. Charles Creighton, "Plague in India."

Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Faraday Society (in the Library of the Institution of Electrical Engineers), 92, Victoria-street, S.W., 8 p.m. Dr. T. M. Lowry, "An Application to Electrolytes of the Hydrate Theory of Solutions."

Royal Institution, Albemarle-street, W., 5 p.m. Prof. Sir James Dewar, "Flame." (Lecture III.)

Historical, Clifford's-inn Hall, Fleet-street, E.C., 5 p.m.

Numismatic, 22, Albemarle-street, W., 7 p.m.

Camera Club, Charing-cross-road, W.C., 8½ p.m. Dr. W. H Workman, "Further Explorations in the Himalayas."

Friday, May 19...Royal Institution, Albemarle-street, W. 9 p.m. Sir Charles Elliot, "The Native Races of the British East Africa Protectorate."

North-East Coast Institute of Engineers and Shipbuilders, Westgate-road, Newcastle-on-Tyne, 7 p.m.

Art Workers' Guild, Clifford's-inn Hall, Fleet-street, E.C., 8 p.m. Paper on "Illuminated MSS."

Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m.

Saturday, May 20...Royal Institution, Albemarle-street, W., 3 p.m. Dr. J. G. Frazer, "The Evolution of the Kingship in Early Society." (Lecture I.)

Journal of the Society of Arts.

No. 2,739. VOL. LIII.

FRIDAY, MAY 19, 1905.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

NOTICES.

NEXT WEEK.

MONDAY, MAY 22, 8 p.m. (Cantor Lecture.) H. W. RAVENSHAW, Assoc. M. Inst. C.E., "The Uses of Electricity in Mines." (Lecture II.)

TUESDAY, MAY 23, 4.30 p.m. (Colonial Section.) SIR CHARLES H. T. METCALFE, Bart, M.Inst.C.E., "The Cape to Cairo Railway."

WEDNESDAY, MAY 24, 8 p.m. (Ordinary Meeting.) KILLINGWORTH HEDGES, M.Inst.C.E., "Modern Lightning Conductors."

Further details of the Society's meetings will be found at the end of this number.

CANTOR LECTURES.

On Monday evening, 15th inst., Mr. H. W. RAVENSHAW delivered the first lecture of his Course on "The Uses of Electricity in Mines."

The lectures will be published in the *Journal* during the autumn recess.

APPLIED ART SECTION.

Tuesday evening, May 16; REGINALD HUGHES, D.C.L., in the chair.

The paper read was on the "Excavation of the Oldest Temple at Thebes," by H. R. HALL, M.A.

The paper and report of the discussion will be published in a future number of the *Journal.*

INDIAN SECTION.

Thursday afternoon, May 18; SIR DENNIS FITZPATRICK, K.C.S.I., in the chair.

The paper read was on "Plague in India," by CHARLES CREIGHTON, M.D.

The paper and report of the discussion will be published in a future number of the *Journal.*

BUST OF THE LATE SIR EDWIN CHADWICK.

The Council have received a terra cotta bust, by George Tinworth, of Sir Edwin Chadwick, K.C.B., the eminent Sanitarian, who was a prominent member of the Society of Arts from 1847 until his death in 1890, and for many years a member of Council, and Vice-President. The bust has been presented to the Society by Sir Edwin's daughter, Miss Marion Chadwick.

CONVERSAZIONE.

The Society's Conversazione this year will take place at the Royal Botanic Gardens, Regent's-park, on Tuesday evening, July 4, from 9 to 12 p.m.

The programme of arrangements will be announced in future numbers of the *Journal.*

PROCEEDINGS OF THE SOCIETY.

TWENTY-FIRST ORDINARY MEETING.

Wednesday, May 17, 1905; LORD STRATHCONA AND MOUNT ROYAL, G.C.M.G., High Commissioner for the Dominion of Canada, in the chair.

The following candidates were proposed for election as members of the Society:—

Bell, Sir Hugh, Bart., Rounton-grange, Northallerton, and 95, Sloane-street, S.W.

Faulkner, Alfred Robert, Fairholme, Worple-road, Wimbledon.

Knowles, Mrs. Marian, 24, St. Edmund's-terrace, Regent's-park, N.W.

O'Shaughnessy, Hugh Patrick, Executive Engineer, South Indian Railway, Trichinopoly, India.

Tate, James C., St. Malo, Seaford.

Vernon, William Henry, The Laurels, Livingstone-road, Birchfield, Birmingham.

The following candidates were ballotted for and duly elected members of the Society:—

Cato, W. C., Malvern, Augusta-road, Hobart, Tasmania.
Davis, Charles E., 847, North Church-street, Rockford, Illinois, U.S.A.
Parker, Critchley, Broken Hill-chambers, 31, Queen-street, Melbourne, Australia.
Ruffer, Henry, Menival, Crystal Palace Park-road, S.E.
Sheath, James T. T., 87, City-road, E.C.
Sturgess, Archibald T., M.I.Mech.E., Messrs. Sturgess and Foley, Alcala 52, Madrid, Spain.
Thompson, Charles Herbert, F.C.S., Enville-street, Stourbridge.

The paper read was—

THE USE OF WOOD PULP FOR PAPER-MAKING.

By S. Chas. Phillips, M.S.C.I.

It was with peculiar pleasure that I accepted the compliment you were good enough to pay me, when you invited me to read a paper on the subject of "Wood Pulp." I have been reminded of the fact that there are in this Society many members who have no practical acquaintance with paper-making or with the subject I am trying to deal with to-night, and therefore, I hope to avoid technicalities as much as possible, although I think you will readily see it is necessary in a paper of this kind to deal in a general way with the evolution of the wood pulp industry, and particularly in its application to paper-making, and in this connection, to deal historically with the progress of pulp-making and its chemical treatment. I think, perhaps, I need scarcely say at the outset, that in the cheaper forms of paper, as we know it to-day, the raw material is substantially wood. I am aware that if you were to ask "the man in the street" of what paper is made, you would probably be told "rags;" but although that used to be the case, the use of paper to-day is so extensive that it would be impossible to meet the demand for one-thousandth part of the total consumption, if the paper-maker had to rely on rags, and I think I may here say that it is due to the engineer and to the chemist that we owe our cheap Press, and largely to the fact that wood has been taken full advantage of in its application to paper-making. For reasons which I may refer to later on, it is obvious that although England holds its own very comfortably at present as a paper-making country, it is not at all probable that Great Britain will ever produce wood for paper-making on a commercial scale. Not long ago, one of our leading paper-makers, whilst referring to this subject, observed that we might hope to make wood pulp here when we had the water-falls and timber forests of Canada, Norway, or Sweden. There was a great deal of truth in that remark, and although there are gentlemen who are sanguine that we might make very much more use of our forests and unproductive land than we do, that we might turn it to good account for timber growing, I do not think that for practical purposes we need, at the present moment, take that into consideration. We may (and I am speaking from practical knowledge) dismiss Great Britain out of the calculation when we are dealing with the great countries which are providing us with timber for the production of wood pulp, and are likely to do so for very many years to come. It may, I think, be said, roughly, that the wood-pulp industry has established itself and attained its present position during the past quarter of a century, There was a time within my own recollection when the manufacturers of high grade papers in this country looked askance at wood, and I know of a gentleman in the wood-pulp business who told me that about twenty years ago when he waited upon a well-known Maidstone firm, and tried to induce them to give a trial to good chemical wood pulp, the owner of the mill was very rude to him, and almost ordered him away from the place. But times have changed since then, and at the present moment many of the mills which in the early days of wood pulp derided its possibilities would not hesitate to place a very large order for the same, at what they might consider a reasonable price. To those who are uninitiated in what I may term the elementary details of the wood-pulp industry, it may be necessary to mention that for the purposes of a paper of this kind, we must bear in mind that there are, to put the matter broadly, two methods of transforming raw wood into pulp.

Mechanical and Chemical.

I have, I may say, travelled a great deal in the principal pulp-producing countries, particularly Sweden, Norway, Finland, the United States, and Canada, visiting the most up-to-date mills where all classes of wood pulp are made, and so have had excellent opportunities

for studying and comparing the various processes now in use. Sweden and Norway are countries from which we have for years derived our principal supply of wood fibre for paper-making. Years of practical experience have taught the Scandinavians to produce the best wood pulp in both mechanical and chemical varieties; but although both Sweden and Norway claim to have enormous forests of pulp wood, yet in spite of the law in Sweden which compels the replanting of six saplings for every tree cut down, it seems to me that at the rate at which the forests are being denuded of their timber for other purposes besides the conversion into wood pulp, in less than twenty-five years from now the maintenance of the timber supply will become a grave question. While in South Germany timber fit for pulping can be grown in fourteen or fifteen years, in Scandinavia it takes about forty years.

During the past dozen years our great Dependency in the Western Hemisphere, viz., the Dominion of Canada — of which our distinguished Chairman, Lord Strathcona and Mount Royal, is the representative in this country—has come forward as a pulp-producing country, much to the relief and satisfaction of British paper-makers; for, with the growth of Canadian competition, it has become an important factor in keeping the prices of pulp from Sweden and Norway from being advanced higher than was justified in normal times. So that the advent of Canada into the wood-pulp business is likely to have a steadying influence in the matter of prices. I am pleased to say that Canada is making great progress in the industry by the construction of new mills, and the extension and improvement of existing mills. Our Chairman (Lord Strathcona) takes a keen interest in the wood-pulp industry of Canada, and has been largely instrumental in its development. As a frequent visitor to Canada, I trust that the Canadian Government will not be long before it adopts the replanting system of Sweden and Germany. At present there is but little attempt to protect the colossal and magnificent forests of the great Dominion of Canada, which are the envy of the whole world. What with the enormous wastage that goes on, and the serious inroads made by forest fires and indiscriminate cutting, Canada will have to take speedy steps to take care of the magnificent and great wealth which Nature has endowed her with in her forests, or otherwise she will, long before the present century closes, be bereft of that grand birthright.

In an essay published by Réaumur in the eighteenth century there is a suggestion that it might be possible to make paper from wood, and in 1750 paper was made from the bark, leaves, and wood of various trees in France. The class of wood generally used for the manufacture of chemical pulp is known as soft wood, and belongs to the order Coniferæ, or cone-bearing trees. The common spruce and the silver fir are the chief species that supply the chemical pulp of Europe, while the white spruce, black spruce, Canadian Hemlock, white American pine, and the silver fir furnish the bulk of wood pulp in America. For mechanical wood pulp, poplar, aspen, spruce, and fir are mostly used. Although almost every class of wood can be converted into pulp, only the soft coniferous trees are economically suitable. Trees having a diameter of from 6 inches to 20 inches at the base, and of about twenty years' growth are considered best. Smaller logs are not so economically worked, and larger timber is usually cut for lumber. Within the last few years a great number of pulp mills have been started in the southern and western States of America, and other parts of the world, which, in order to utilise the particular class of wood growing in those districts have adopted somewhat special methods, and we now find wood pulp being produced from a great variety of woods. The great majority of pulp mills obtain their supply of wood in the form of round logs about 6 to 10 feet long, while many in the lumber cutting districts use edgings and other waste wood from sawmills.

Sawdust has also been experimented with for the purpose of producing chemical fibre, but owing to the difficulties of getting the solvent liquor to circulate readily through it, and other troublesome features, it has been found to be impracticable. Shavings would be more suitable for converting into wood fibre, and are employed by some, although their bulkiness prevents any substantial weight being dealt with in each boiling operation. They might, however, be more conveniently used if they were first put through some form of machine similar to a hay-cutting mill, and reduced to small lengths.

Like ordinary lumber, the logs employed for pulp-making are generally cut by gangs of woodmen, who camp out in the forest during the winter months. In the early spring, when the snow and ice begin to melt, the logs are easily conveyed to the banks of the river, which, being at this time naturally swollen,

carries them down to their destination. The log-driving men's duty is to keep them off the banks, and clear of obstacles, until they reach the saw or pulp mill, where booms, consisting of a number of logs chained together endwise, are stretched across the river to prevent them from being drifted any further. By this means millions of feet of logs are annually brought from the centre of the forests down to the mills. The result of being in the snow and water, and the friction in driving, is such that the logs generally arrive at the mill with the bark entirely removed.

In Europe, Scandinavia, Russia, Austria, and Germany possess the largest wood pulp forests, which, in the former countries, are the natural virgin growth, and still very extensive, in spite of the enormous quantity annually cut. In Germany the original natural forests have been almost exhausted, but owing to the wisdom and foresight of the authorities, they have been replanted and grown under Government supervision. Undoubtedly the American continent has the largest supply of pulp wood, but even the extensive forests of the Adirondacks and similar districts round the large paper-making centres are rapidly becoming depleted by the pulp manufacturers. The State of Maine and other New England States have still enormous quantities of uncut pulp wood, but unless measures are taken to preserve and cultivate them, the present rate of cutting cannot be indefinitely continued. The immense virgin forests of pulp wood in Canada and Newfoundland are practically untouched at present, but the day is not far distant when great demands will be made upon these forests.

Pulp wood is generally bought by measurement; the fact that the amount of water contained in the wood varies so considerably prevents any method of dealing with it by weight. The method of measuring timber is also very troublesome and unsatisfactory, more especially by the tape or quarter-girt system. Measuring in fathom frames is costly work, and, like pile measurement, varies according to the skill or otherwise of those piling the logs. In America, wood is generally bought by the cord, which equals 128 cubic feet pile measurement. In Great Britain and Scandinavia it is usually bought by the fathom, which is a cubic pile of logs 6 feet long, and piled 6 feet high, containing 216 cubic feet. In many of the Continental countries it is purchased and sold at so much per cubic mètre.

The appellation, wood pulp, includes two distinct varieties having different chemical compositions and properties. These are known in commerce as mechanical or ground wood pulp, and chemical wood fibre or wood cellulose. The former is simply wood ground, washed, and made into layers or sheets; while the latter, or chemical wood pulp, is produced by treating the wood with various chemicals to remove the ligneous and mineral compounds, leaving the soft, pliable cellulose fibres almost pure. Of the chemical pulps, there are also several varieties, named according to the chemical solvent employed in the manufacture—we have sulphite wood fibre, soda fibre, and sulphate fibre, or pulp prepared by the action of sulphate of lime, caustic soda, and a solution of sulphates of soda, respectively.

Wood-Stuff, or Mechanical Wood Pulp.

Dr. Joseph Bersch, a well-known authority, describes mechanical wood pulp as wood converted by purely mechanical means into a fine-fibred mass, which by itself may serve for the production of coarser grades of pasteboards as well as for the manufacture of various articles. Its chief use, however, is as an addition to paper stock for the manufacture of inferior grades of paper. Although wood-stuff, if properly prepared, is sufficiently fine-fibred to be made into paper in the paper machine, it is not used by itself for this purpose, because such paper possesses the undesirable property of becoming darker and acquiring, in a short time, a brown colouration when stored exposed to the light. The cause of this phenomenon is, in Dr. Bersch's opinion, found in the fact that the wood-stuff still contains nearly the entire quantity of encrusting substance—lignin, &c.—originally present in the wood, these substances being subject to great changes. Hence, in the course of time efforts were made to remove these substances from the wood, so that only pure cellulose remains behind, which, as it does not show the already mentioned defects, can be used practically by itself for the manufacture of paper.

Wood for Grinding.

Although practically every kind of wood may be made use of and put into the grinder, some woods are far preferable to others, and of the European varieties of wood, ash, linden, fir, pine, and birch are particularly suited for the

purpose; whilst beech may be used, but is considerably less suitable.

The views on the screen will convey a good idea of the practical operations.

Mechanical Wood Pulp as Made in 1844.

In 1844 there was patented in Germany a machine for grinding wood for the manufacture of pulp. The inventor, Keller, sold the patent to the firm of Henry Voelter's sons, who afterwards used the pulp in the manufacture of "news" paper.

The Voelters made numerous improvements in Keller's invention, and a quarter of a century after it was patented in Germany by Keller this wood pulp machine was destined to play an important part in the United States, when, in response to the demand for the rapid printing of daily newspapers, the web press was to come into use. The Voelters—Christian and Henry—made numerous improvements in the machine, Christian Voelter obtaining patents in various European countries—in France even as early as April 11th, 1847. Henry Voelter patented his improvement on the pulp machine in Würtemburg, Germany, on August 29th, 1856, and in the United States on August 10th, 1858.

Various methods of treating wood previous to submitting it to the action of the grinders have been proposed and used. By one process the logs of wood, after being cut into suitable lengths for grinding are treated by first steaming them, then removing the acids generated in the steaming operation, next treating the steamed wood with alkali, and, finally, grinding or reducing the pieces to pulp. Steaming has been resorted to for the purpose of removing the bark from wooden blocks preparatory to grinding the solid parts; and wood has also been treated with water sprinkled on it from above, and steam simultaneously applied from beneath it, in order to soften and cleanse it preparatory to grinding.

But the process which we shall now describe, which is that of Mr. George F. Cushman, of Barnet, Vermont, is intended to facilitate the disintegration of the fibres, when submitted to the action of the revolving stones by a preliminary cooking of the block of wood in a bath of boiling hot water with lime, soda-ash, or equivalent chemical agent in solution, to soften the block, toughen the fibres, and lessen their lateral adhesion. By this process the block is reduced to pulp with much less power than is required to grind a block not so treated; and the pulp produced is claimed to be softer, stronger, and more desirable, since the fibres are not broken up or comminuted, but are more nearly in their natural condition, with their lateral beards or filaments preserved, so that when re-united in the paper sheet special toughness and tenacity are attained.

In carrying out this method, I believe it is usual to immerse the solid wooden blocks in a strong solution of lime, soda-ash, chloride of lime, or equivalent chemical agent, kept boiling hot by the introduction of steam or otherwise, and adapted to soften the blocks in readiness for grinding, and retain the blocks under treatment from ten to twenty-four hours, or until the liquid has had time to penetrate all parts of the block, and the lateral adhesion of the fibres is so weakened that they will readily separate by the attrition of the grinding-stone without being broken short or reduced to a mere powder; and as the chemical action is most rapid in the direction of the length of the fibres, it is desirable to cut the block much shorter than is usual, or to form tranverse saw-scarfs at intervals between its ends, in order that the solution may readily penetrate from each end to the centre, so as to loosen and toughen the fibres throughout the block. The pressure of steam above the liquiid in the tank tends to force the solution into all the pores of the immersed blocks; then remove the blocks from the tank and subject them to the action of the grinders in the usual way, kseping a constant stream of water upon the stone, and the disintegration will be found to be effected with great rapidity, owing to the preliminary treatment received by the blocks, and also that no washing is required beyond what results from wetting down the stone. The pulp produced is claimed to be of superior quality, and as the blocks have absorbed only so much of the chemicals as is beneficial to the fibre, it is in condition for the successive steps in the production of various grades of paper of special strength, and for numerous other purposes in the arts. If preferred, however, this fibre may be mixed with hard stock made of other material, such mixture producing paper or board of exceptional toughness.

Voelter's Machine for Cutting or Grinding Wood and Reducing it to Pulp.

The art of reducing wood to pulp by subjecting the same to the action of a revolving stone is not a new one, machinery for grinding wood while a current of water was applied to the

stone having been patented in France by Christian Voelter as early as 1847 (*see* "Brevets d'Invention," vol. x., second series), and in England by A. A. Brooman, of London, in 1853 (*see* "Repertory of Patented Inventions," for May, 1854, p. 410).

A large number of inventions for cutting or grinding wood into pulp have been patented; but the enormous development of the paper-making industry, and the cheapening of paper during the last fifteen years are largely due to the general introduction of the machine for disintegrating blocks of wood and assorting the fibres so obtained into classes according to their different degrees of fineness, invented by Mr. Henry Voelter, of Heidenheim, Würtemburg, Germany, and for which invention he received letters patent on August 10th, 1858, from the United States.

In all the processes known or used prior to Voelter's invention the wood had been acted upon by the stone in one or two ways, viz., either by causing lhe surface of the stone to act upon the ends of the fibres, the surface of the stone moving substantially in a plane perpendicular to the fibres of the wood; or, secondly, by acting upon the fibres in such a direction that they were severed diagonally, the surface of the stone moving diagonally across the fibres. The first plan, in fact, made powder of the wood—an obviously unsatisfactory result. The pulp had no practical length, and on trial proved worthless, or nearly so. The second plan was carried out by the use of a stone revolving like an ordinary grindstone, the wood being applied upon the cylindrical surface thereof, the fibres perpendicular, or nearly so, to planes passing through the axis of the stone and the point or locality where the grinding was performed; and this plan also failed, because the fibres were cut off in lines diagonal to their own length, and were consequently too short to make good pulp. There were other difficulties attending the process not necessary here to mention. Such was the state of the art prior to Voelter's invention; and his improvement in the art consists in grinding or milling away in detail from the bundles of fibres which make up a piece of wood by acting upon them by a grinding surface which moves substantially across the fibres and in the same plane with them. In carrying out this improvement upon the art Voelter splits a log of wood and applies the flat side upon the stone, and then the stone so revolves as to cause points upon its surface to pass the fibres in lines perpendicular, or nearly so, to the length of the fibre. By this mode of procedure it is possible to obtain a sufficiently long fibre and save much power. Voelter's improvement in the art consists, further, in re-grinding the fibres by causing them, after being separated from the block, to pass under other blocks of wood, which are being reduced to pulp upon the same stone. The fibres torn out at the first operation are thus rolled over and crushed again and separated into smaller fibre.

Voelter's improvements in the machinery are in an arrangement of pockets with reference to the grinding surface, so as to hold the blocks of wood in such position that their fibres may be separated from the blocks in the manner described, and whereby fibres may be re-ground, and in a contrivance for feeding up the blocks by a positive feed instead of by force derived from weights or springs, as formerly practised; and a contrivance for causing the feed to cease automatically.

On May 22nd, 1866, Mr. Voelter was granted another patent for improvement in his machine for reducing wood to paper pulp, which patent was re-issued on April 23rd, 1872.

Bachet-Machard Process of Disintegrating Wood.

Messrs. Iwan Koechlin and Co. have carried on the Bachet-Machard patent at the Isle Saint Martin, near Chatel (Vosges), France, and it has also been experimented with on a large scale at Bex and at St. Tryphon, Switzerland. At the start the inventors had in view the saccharification of wood, the paper pulp being intended to be only a secondary product of the manufacture of alcohol; but in practice the inverse result has been obtained, the paper pulp becoming the principal product, and alcohol the secondary one.

The wood, previously sawn in thin discs, was thrown into tubs, the filling of which was then completed with water and sulphuric acid, the latter in the proportion of one-tenth. Each tub would contain 188 cubic feet; eighteen hours' boiling was needed; the discs were then washed as well as possible in order to eliminate the acid, then passed through the crushers and the mills. Each 31⅓ cubic feet produced about 330 lbs. of dry pulp; 65 lbs. of acid and 136 lbs. of coal were used for the p oduction of 220 lbs. of pulp. Calculating the value of the wood at 38 cent. per cubic foot, the cost of production of 220 lbs. of pulp would be 8s.

With the Bachet-Machard method a brown

pulp is obtained producing a good brown folding paper costing about 3s. 6d. per 100 lbs. dry pulp. This brown pulp is easily transformed by a half bleaching into a blond pulp costing about 8s. 4d. per 100 lbs., and this can be utilised with or without mixing, for the manufacture of wrapping paper and of all the coloured papers. Up to the present time a method for economically transforming this into white pulp had not been found (1. "Dictionnaire de Chimie," Wurtz, tome ii., p. 749, *et seq.*).

The inventors think that the tenth of acid, which they cause to react at 212 F. upon the wood, saccharifies the ligneous, or rather the incrustating substance without touching the cellulose fibres; thus the cellulose becomes easily separated into fibres by mechanical means. It is probable that the acids modify the incrustating substance and render it friable, and that at the same time certain principles of the wood are converted into glucose.

The process is the same as with straw and esparto, when alkaline washes are used; but it requires more energetic boiling; the proportion of alkali is doubled, and the boiling done at a pressure of 165 lbs.

A little more chlorine is also required for the bleaching. In this country common "news" requires to have about 20 per cent. of sulphite to hold it together on a fast-running machine. In America it can be produced with 100 per cent. mechanical, the reason being that mechanical coming direct from the grinders has greater felting powers than if converted into pulp and shipped to this country. This point is a matter of considerable economical importance, and probably accounts for the difference got with fast-running machines between England and the United States of America.

I have explained that mechanical or ground wood pulp can only be used alone for inferior grades of paper, and must be used direct from the grinders on to the paper machines. A combination of about 70-80 per cent. of mechanical wood pulp fibre, and 20 to 30 per cent. of chemical produce the "news" on which our daily newspapers are printed.

The manufacture of wood pulp is undoubtedly a most interesting study which has closely occupied the minds of eminent scientists and experts for years, and new facts are being brought to light. Indeed, wood pulp as a field of research, seems inexhaustible.

Quite recently I visited the important paper and pulp mills of the Munksjö Company at Jönköping, in Sweden, where the manufacture of what is termed "Kraft" paper was discovered, tradition says by accident, although Mr. Hagborg says that the method was arrived at after long and careful experiment.

Wood pulp is used solely in the production of many thousands of tons of boards, which are used by bookbinders, paper boxmakers, and others. I might mention that in the various pulp-producing countries many millions of pounds sterling are invested in the production of pulp. A large proportion of this is British capital.

Reverting to the question of

GROUND WOOD,

or, as it is generally known in this country, mechanical, it may be said that the method of logging and of conveying the cut timber from the place where it falls into the mill, is governed largely by local conditions, which I shall deal with subsequently. But when once the wood is at the mill, the method of transforming it into mechanical wood pulp is to-day a simple one. The blocks of wood are put into a barking machine, a common form of which is provided with three knives upon a rapidly revolving drum. The blocks of wood are brought in contact with these knives, and it is essential that the bark is thoroughly cleared away, otherwise the pulp will show dark spots. Knotty wood is also objectionable, and as far as practicable, knots have to be removed, and in many mills this is achieved by means of a revolving auger or a spoon-shaped auger. The wood is cut into blocks by circular saws, and it should be finally split in order that the inside of the wood may be examined, as it is undesirable that any decayed timber shall be made use of. Only sound wood should properly be used, as the effect of rotten wood is sure to be detrimental to the pulp. The actual process of grinding the wood is simple. Every kind of machine for grinding consists of a grindstone (of sandstone), which runs at a very rapid rate, and against the surface of which the wood is pressed, the latter being kept constantly wet by a copious water supply. The wood is fed into what are termed pockets, and placed so that its vascular bundles lie parallel to the surface of the grindstone. The latter, in revolving, tears from the wood individual vascular bundles, and occasionally large splinters. The mass is carried by the water into a vat, in which the revolving stone is placed, and from there to the sorting contrivances, by which various sized particles of wood are separated from the other. In some

modern grinders, the stone is fixed to a vertical shaft, but most authorities consider a horizontal position preferable. If time permitted, I would like to have described in detail the various types of machine in use in various countries, of which the principal ones are; Voelter's, Oser's, Voith's, Freitag's, Abadie's, and others. In this connection it is highly essential that the water used shall be pure and free from suspended solid bodies, sand or clay being particularly objectionable, as they cling to the pulp, and affect it considerably when it gets into the paper-maker's hands. It is, therefore, of course, highly necessary that in establishing the site for a pulp-making centre, there shall be a suitable water supply, otherwise the water used for grinding must be carefully filtered, and in some mills where the water is not all that could be desired, the water, after it had passed through the sorting screens, is collected, filtered, and again used.

SORTING PULP,

which follows the grinding, is a very important detail. The sorter is, in fact, a kind of sieve or series of sieves, and Voith's shaking sieve is probably one of the best types in use. The frame rests on steel springs, and the cranked axle, by an ingenious arrangement, secures uniform running, whilst the sieves jerk and shake rapidly, 400-500 motions per minute. The application of springs reduces the wear and tear very materially, and also minimises the noise. The particles of brown wood, having thus been mechanically sorted, the pulp is conducted to the settling vats, the dehydrating apparatus, or the board machines, as may be desired. There are various processes for dealing with the particles of wood which would not pass through the sieve, and, generally speaking, it may be said that they are re-ground and again passed through a fine meshed sieve.

The removal of water from pulp is a very important element, which has to be taken into consideration, especially where the question of freight has to be considered; and as a considerable quantity of pulp has to be shipped over large distances, it is obvious that it is not desirable to carry more water in the pulp than circumstances necessitate. Therefore, the importance of this is a matter which has a considerable bearing on the immediate advantage which accrues to a mill in the position of making up its paper from pulp on the spot, but the full consideration of this subject is a matter which is rather outside the scope of this paper. There are many forms of drying apparatus, and the preparation of perfectly dry pulp is now quite practicable. As bearing upon the importance of selecting wood of the right class for the particular purpose intended, I may here observe that Prof. Winkler made interesting experiments with pulp from different varieties of wood, which was exposed to the action of the air at a temperature of between 30° to 50° F., and he obtained most interesting results, which are fully set out on page 42 of Bersch's book.

To those of my audience who desire to go thoroughly into the chemistry of paper-making, I can recommend a publication on this subject by R. B. Griffin and A. D. Little, published by Howard, Lockwood and Co., New York. From memory, I believe the book I refer to was published in 1894. It contains a mass of information of a very useful character. Other valuable books to those who desire to go into the matter of wood pulp thoroughly are :—"Vegetable Physiology" (Goodale), also Schubert's "Die Cellulosefabrikation," and amongst our British authorities, the writings of Mr Clayton Beadle, Messrs. Cross and Bevan, Dr. Stevens, and Mr. R. W. Sindall are amongst the most instructive; whilst the lectures delivered before this Society not very long ago by my friend, Mr. Julius Hübner, of the Manchester Technological School, also afford much information on the subject of paper-making generally, and on the treatment of wood pulp from the paper-maker's point of view.

CRUSHING.

Another interesting process in the preparation of mechanical wood pulp was known as the crushing process, and the effect is the preparation of pulp from steamed wood without the necessity of grinding. This has been known as the Rasch-Kirschner method. The steamed wood was first converted into small pieces by means of a chopping machine of special design, and then the wood was cut by a knife mechanically driven lengthways into shavings of fixed size. or lengthways as well as crossways. The small pieces of wood were then further reduced by mechanical means, having first been subjected to the action of a stamping mill, and eventually were put into the Hollander, and I am told that a very decent class of brown boards or stout wrapping papers could be made in this way, and it is stated that boards and paper especially suit-

able for roofing purposes made by this process had special advantages. Some of such boards, impregnated with coal tar, were said to be specially adapted for resisting the action of the weather, and are described as "perfectly indifferent to water as well as to changes of temperature." Attempts have been made to bleach the pulp made from steamed wood, but so far as I can learn the results were not commercially successful.

Although it may possibly, strictly speaking, be somewhat beyond the natural scope of a brief paper of this kind to go into the commercial details of wood pulp making as regards cost, I have been favoured by a gentleman who is in a special position to obtain information of this kind with some very interesting figures. I am told that it requires 80 h.-p. to make one short dry ton per day, or say, 90 h.-p. to make one long dry ton per day, so that a mill developing 1,800 h.-p. on the turbines should produce 20 tons of dry mechanical pulp per day, or say, 12,000 tons per year of 300 working days. Some Norwegian mills have very small horse-power on the stones, but the latest and most modern mills have at least 250 h.-p., whilst the Canadian mills are calculated on a basis of 300 to 350 h.-p. per stone, and very large stones are used. On the subject of the actual cost of producing mechanical pulp, I am told that a pretty reliable estimate of the cost of the wood necessary to make a ton of dry pulp is approximately:—

Dry Pulp.

In East Norway .... from	25s.	to 30s.
In North Sweden .... "	22s.	to 25s.
Canada: Lake St. John and portions of Nova Scotia	13s. 6d.	to 15s.
St. Maurice River and other districts........................	15s.	to 22s.

Wet Pulp.

The net cost, allowing for depreciation, is given approximately as follows:—

	Per Ton, Dry Weight. £	s.	d.
Modern mills in Norway, C/a......	3	0	0
Modern mills in Sweden, C/a........	2	15	0
Lake St. John	1	17	6
St. Maurice District................	2	10	0

On this subject, it should be borne in mind that the capitalisation of a modern pulp mill is very high, and for a mill making, say, in Scandinavia 6,000 tons wet, and 3,000 tons dry, f.o.b., value (roughly) £10,800, the mill capitalisation would necessarily be from £20,000 to £25,000; and hence it follows that to make 10 per cent. on the capital a net profit on the produce of from 20 to 25 per cent. is necessary.

Small mills such as these form the majority in Scandinavia; but mills of this class could not be made to pay in Canada, were the biggest mill (Chicoutimi) made 48,000 tons of short wet pulp in six months. The entire capitalisation on this basis is 27 dols. per short ton dry per annum, or, say, £6 5s. per ton dry weight (2,240 lbs. per year), making the value of a short dry ton to be 13·50 dols. f.o.b. On this basis, a good return will be shown, viz., a net profit of 20 per cent. on the article yielding 10 per cent. for the purposes of dividend.

In the matter of the general cost of good bleaching pulp, of course, local conditions here, as in the case of mechanical pulp, have a considerable influence; but I am told that good bleaching pulp may be produced at a cost net (including everything, with the exception of interest and depreciation) at about the following figures.

In Norway, at modern mills, about £6 per ton at the mill; unbleaching qualities would probably cost about 10s. per ton less. In Sweden the cost varies considerably, but about £5 may be stated for "news" pulp, and £5 10s. for bleaching; and this is, I think, a low estimate and can only be applied where the most favourable conditions are in operation. So far, practically, no success has attended the Canadian pulp mills in the manufacture of chemical pulp, and this I attribute largely to lack of knowledge of the technicality of sulphite-making, and through the lack of organisation as to timber supply. Mills have been put down where timber could be had before building for 2·50 dols. to 3 dols. per cord in limited quantities, but owing to lack of organisation and adequate security for the continuity of supply, prices have been forced up in Canada to 5 and 6 and even 7 dols. per cord, which is higher than in Scandinavia. On the subject of capitalisation, a modern mill would be doing well if capitalised so that every £5 of capital produced one long dry ton per year; but most mills are, I think, capitalised on a great deal higher basis than this, and the fact is, of course, obvious. This, however, is much better than mechanical making, as 10 per cent. net on the article will nearly always give more than enough for a 10 per cent. dividend.

The Use of Wood in Paper-making.

The first time, perhaps, that wood was used to any appreciable extent in the manufacture of paper was when Koops published his book, in 1800; but at that period it could not be made to compete successfully against rags. The European wars had the effect of raising the price of rags at the beginning of last century, so much so, that there was a law which prohibited the burial of the dead in linen shrouds.

Mechanical wood, or mechanical pulp, as we know it to-day, is, as I have already said, produced by keeping short cut pieces of wood by hydraulic pressure against the surface of a rapidly revolving stone, and was the first form in which wood was used in any considerable quantity.

Mechanical wood has very little felting power, and is only capable of producing a weak paper, which contains practically all the ingredients of the original wood, and from the time of its discovery up to the present it has only been used for lower class papers. It, however, constitutes the great bulk by weight of our paper-making materials, as a common newspaper contains upwards of four-fifths of this substance.

Chemical Pulp.

A great change took place in the manufacture of paper on the development of the sulphite process. This process consists in treating chips of wood under a pressure of about seven atmospheres with a solution of bi-sulphite of lime or magnesia for a period of from eight hours to three days. The first patent was undoubtedly taken out by Benjamin G. Tilghman, of Philadelphia, in 1867. His original specification practically covers the various methods employed by subsequent inventors. He started by boiling in lead-lined cylinders. Although an excellent fibre was obtained the engineering difficulties rendered it necessary to abandon his original process.

The preparation of wood for the chemical process is somewhat similar to that employed in preparing the wood for grinding. The wood is brought from the river or from the stacks in the mill yard, sawn into suitable lengths, passed through the barking machine, then through the knotting machine, afterwards fed into the chipping machine, which, at a great rate, reduces the wood into small chips. It is then screened, and any further knots which appear are removed, and then the wood is taken along by a conveyer from the screens to the top of the digester house, and fed into the digesters through the manhole at the top. I have seen, at the modern Chemical Pulp Mills, in Sweden, Norway, Finland, United States, and Canada, digesters with a capacity of 15 tons dry pump, and I have heard of a mill in North Sweden with a digester which will carry at one cooking 20 tons of dry pulp.

The Pioneers of Chemical Pulp.

The actual date of the invention of wood pulp is more or less problematical, as the evolution of wood pulp has undoubtedly extended over a very considerable period, but the reference to Tilghman may be accepted as established. Some years ago a very interesting correspondence appeared in *Papier Zeitung*, and Professor F. Fittica asserted that (*a*) Mitscherlich was entitled to the honour of being recognised as the inventor of sulphite. The editor of *Papier Zeitung* apparently did not wish to share the responsibility for that statement, and I think the editor of our esteemed German contemporary was well advised in the view he took, and in the course of a very intelligent correspondence, various more or less authoritative people put forward the names of Ekman, Tilghman, Rismuller, and others, and various information was forthcoming regarding priority, but the consensus of opinion seemed to controvert Professor Fittica's original argument, and *Wochenblatt* mentioned C. D. Ekman as the father of the sulphite industry. About the year 1872 a well-known publication, in discussing this particular matter, argued that it was due to Ekman that the manufacture of Mitscherlich's cellulose on a large scale was rendered chemically possible. Prof. Fittica, however, who stuck to his guns in championing Mitscherlich, said that Ekman did not operate with calcium sulphite according to Mitscherlich's process, but he used magnesium sulphite, a salt that was without value owing to its inconstancy, and, consequently, was of no technical consequence as compared with calcium sulphite, but subsequently Ekman undoubtedly made a success of the magnesium sulphite process. However, his method was kept secret so that even for that reason the same could not have been, in Fittica's opinion, used by Mitscherlich. In this connection it is worth while remembering that originally Ekman's mill was in operation from 1874 to 1897, but was, of course, re-opened later. Fittica further stated that Tilghman was ahead of Mitscherlich, in so far as he used

diluted sulphurous acid for transforming wood into cellulose, and it is significant that in the year 1886 Tilghman, in his patent, No. 2924, mentions "that an addition of bi-sulphite of calcium to sulphurous acid is advantageous." However, it subsequently appeared that he had not used the salt alone, nor did he use the comparatively low temperature recommended by Mitscherlich. Moreover, he was unable to surmount the technical difficulties combined with these stated processes, and subsequently discontinued his experiments in the year 1867, after struggling for two years, and losing 20,000 dols. or over. In the year 1882, Ritter and Kellner took out a patent, and at this time Mitscherlich's factory in Munden was flourishing, having been started in 1875, and having made considerable progress, and the friends of Mitscherlich claim that the early manufacturers, in a general and theoretical way, operated on the Mitscherlich principles, their process differing only in insignificant arrangements. Prof. Kirschner states in his work, "Zellstoff," that F. A. Rismuller was the first to produce practically valuable cellulose on a considerable scale, under Mitscherlich's direction, in his factory. The names of O. Vogel, in Zell, is also alluded to by Prof. Kirschner, but there is no evidence that Vogel played any great part in the actual invention, although there is evidence that at one time he was assistant to Mitscherlich, and subsequently Vogel put down his own plant, which was arranged according to the Mitscherlich process. In 1884, in favour of Tilghman, Mitscherlich's patent No. 4179 was suspended by the German Court, and history would support Tilghman's contention. Some reliable authorities point out that sulphurous acid and its preparations had formerly been used only for bleaching cellulose wood pulp, and as late as 1867, after the issue of the Tilghman patent, Mr. Krieg—whose opinion is worth something—emphasised the fact "that wood pulp was not suitable for fine papers." Heldt states that in 1869 sulphurous acid should not only be called bleaching material, but bad bleaching material, because it imparts a yellow colour. At about that time, apparently new methods were discovered to change the wood into cellulose by the use of alkalies, and it is recorded that in 1872 considerable progress was made in this direction. A year later, in 1873, Menzies published a new process, according to which wood was treated in the damp state with chlorine, and in that same year Aussedat seems to have paid considerable attention to bringing wood and chlorine together in steam pressure. Blyth and Suthby made combinations of both the first and last mentioned methods by first submitting the wood to the action of alkalies, and subsequently to high steam pressure, and this method was amplified and improved by Ungerer. Then Mitscherlich came into the market with a new arrangement to use bi-sulphite of calcium, and demonstrated that by a solution of calcium sulphite with strong acids, he prepared a solution of calcium di-sulphite. Following this success, and assisted by the use of Swedish Patent No. 2939, he succeeded during that year in the performance of technical trials on a large scale, and in 1875 he obtained a directly prepared solution of di-sulphite, such as he had previously obtained from calcium carbonate. At that time he obtained the action of pure calcium bi-sulphite on wood, preparing the salt by running sulphurous gas over pieces of carbonate of calcium. Afterwards he constructed a tower for making the bi-sulphite of calcium. This method seems to have been considerably followed, and in 1866 a sulphite mill was built in America on Mitscherlich's lines, and according to a report from Thilmany (1894), the Mitscherlich process had been favourably adopted, and to such an extent that about that time there were forty boilers in operation in the United States and four in Canada; and the total yearly product in the States at that time was about 50,000 tons. On turning to Muspratt's technical handbook of that time, Mitscherlich is mentioned as the inventor of sulphite cellulose. Without committing himself to Stohmann, whose opinion has been freely quoted, it is significant that this authority mentions Tilghman and others, but merely to show that their experiments, as compared with Mitscherlich's success, had no weight, since they were not performed in a practical manner, and because they gained no technical success.

Stohmann, however, was subsequently reminded that the earliest edition of Muspratt contained no mention of Mitscherlich, although his mill in Munden was then in secret operation. Prof. Fittica, on this subject, summarises his opinion in these words: "Tilghman used the sulphurous acid, or he intended to use the same; but he did not use the sour calcium salt of the acid, and did not prepare or use the same in its pure state, in which condition only is it practicable for that purpose. For this reason, Tilghman had to discontinue, after ten years of restless activity." Ekman's magnesium

sulphite, however, undoubtedly and finally proved to be a suitable preparation. Several other experimenters also failed to comprehend the action of the temperature, so that also in this respect we must give Mitscherlich the credit due to him. As might have been expected, Prof. Fittica's contentions provoked very considerable criticism, and some rather severe comments, and returning to the fray, Fittica says in 1904: In my history, in the manufacturing of sulphite stuff, I mentioned especially that it was Tilghman, besides others, who had already undertaken to make experiments to make sulphite fibre by means of sulphurous acids, but that it was Mitscherlich who provided a practical foundation to these experiments, and he must be called the first inventor in case the question arises as to a really practical invention. The germs of the idea of a new invention, a new principle, a new law, a new conception of the universe only take root gradually. Each idea has its forerunner, and these forerunners are present in every direction. . . . The person, however, who forms these ideas in the practical shape must be considered the inventor, because his forerunners have not performed a technical realisation. . . . Consequently," adds Prof. Fittica, "I repeat that it was Tilghman, besides others, who furnished the idea of manufacturing sulphite fibre, but it was Mitscherlich who added hand and foot to the practice, and, therefore, must be called the real technical inventor of the sulphite cellulose fabrication." Quite recently, Prof. E. Kirschner added a very important contribution to this controversy, and wrote that Ekman, in Bergvik, Sweden, produced regularly large quantities of the valued sulphite pulp in 1874. That was long before Mitscherlich, and Prof. Kirschner adds that Fittica did not apparently seem to be aware that magnesium bi-sulphite, and also sodium and potassium compounds, produced not only the same effects in the sulphite process as calcium bi-sulphite, but would be even preferable to the latter, were it not for the higher cost of the bases contained in the former. Prof. Kirschner went at some length to substantiate his arguments by giving interesting chemical details, and went on to observe that "seeing that Ekman, in Bergvik, had not only magnesite, but also lime close at hand, and the latter could be bought at a lower price, we are justified in concluding that Ekman was well aware of the technical conditions offered by a magnesium bi-sulphite liquor in contrast to one prepared from lime. From 1875 and onwards, Ekman pulp was to be found in European markets. Later on, in 1878-1880, the Ekman pulp was certainly of a higher quality and fetched a higher price than the impure irregular material from Hann-munden, where the Mitscherlich process was being worked." Kirschner further controverted the suggestion that the poor qualities attributed to Ekman pulp by Fittica were not justifiable, and he argued that Mitscherlich was largely a copyist of Rismuller and Vogel. To those who are sufficiently interested in the subject, a perusal of Ekman's and Francke's patent specifications for the manufacture of sulphite pulp will probably be of considerable historical interest, and I am indebted to Mr. Clayton Beadle for a perusal of the same. This patent seems rather to bear out the contention that at a certain period quite a number of distinguished men were struggling to place what we now term chemical pulp on a commercial basis, and that Ekman contributed considerably to the solution of the difficulty.

C. D. Ekman (a persevering Swedish chemist), who died last year at Gravesend, therefore appears, in my judgment, to have been the first to make a commercial success of the sulphite process. He set to work in 1872, using a solution of bi-sulphite of magnesia. His process was worked secretly until about 1879, when it was introduced into the Ilford Mills, near London; after which, in 1884, the proprietors of the patent erected large mills at Northfleet, where the process was conducted by the Ekman Pulp and Paper Company, and was finally abandoned in this country in 1903-1904, it being no longer possible to compete with foreign countries, on account of the cost of timber.

The great difficulty in the way of making the sulphite process a success was due to the corrosive action of the sulphite liquor. This liquor quickly eats through iron, and has a certain amount of action upon lead. Lead linings were at first used at Northfleet, but owing to the difficulty of "creeping," lead had to be abandoned. The "creeping" is due to the difference in the expansion of the lead and the outer lining, causing the lead to "pucker." I am informed that the first lining came away completely, like a jelly out of a mould. Many linings were substituted, among them cement. The difficulty was finally overcome by introducing a brick lining.

Wood pulp for paper-making was manufactured at Guardbridge, in Scotland, very

many years ago on the site of the Guardbridge Paper Company's mills. It was also made at Bruce's, at Kinleith Paper Mills. The Messrs. Tait have made wood pulp at their paper mills at Inverurie for over twenty years past. Then a plant was erected at Inverkeithing.

In England, Ekman made pulp at Ilford. Mr. Edward Partington, one of the most experienced authorities on wood pulp in this country—who would have been with us to-night but for the fact that he is leaving for the Continent—made pulp for years at Glossop. The Kellner-Partington Paper Pulp Company also made pulp at their mills at Barrow-in-Furness.

Mr. (now Sir John) McDougall, ex-Chairman of the County Council, made wood pulp at Millwall.

Then there was another company at Goole—which made pulp in 1890, but is now discontinued—and the West Hartlepool Company, which also made wood pulp. Some seventeen or eighteen years ago, I remember being invited to the mills of the East Lancashire Paper Company, where in a small building I saw wood pulp being made by what was then known as the Graham process.

A Scotch friend tells me that the Guardbridge Soda Pulp Mill was erected in 1870-71, and it worked for about two years or so. The boilers were of Mr. Sinclair's patent vertical, having conical ends, the fire being underneath, having spiral flue so that the gases ascended and passed through an iron-funnel chimney on the top. To prevent the burning of the wood, there was provided a perforated cage having 1½ inch space between said cage and outer shell for the liquor. There was a down-take pipe about 5 inches diameter to take down the liquor through the centre of the cage. This down-take pipe was removable, so that it could be taken out when the boiler was being filled. These boilers were 10 or 12 feet deep, and about 4 feet diameter, the working pressure being about 200 lbs. per square inch. Caustic soda was used, and the wood was boiled off in three hours.

The Goole Company commenced making pulp in 1890, but has not been in operation for some time. The North Eastern Pulp Company also turned out pulp, but is not now doing so.

Messrs. Brown, Stewart and Co. had digesters at Newton Paper Mills and at Dalmarnock Mills for making their wood pulp; but this also has all been discarded. This was about twenty years ago.

In those days the cost by Francke's process of wood and chemical plant for the production of 30 tons of sulphite pulp per week was estimated at £8,000, and with the Ekman process—then just at work at Ilford—£13,000 to £14,000 was spent on plant, machinery, and wood to produce 20 tons per week. The cost of raw wood to make a ton of paper at Hull or Liverpool was estimated at £5.

In the early days of sulphite pulp manufacture I went to Sweden and studied the bi-sulphide process at Francke's mills. Mr. Edward Partington and Mr. James Galloway about this time visiting the same mills, with the view of adopting the process. Subsequently Mr. Partington erected a sulphite wood pulp plant at Glossop, and worked a system of his own. In 1844 Keller took out letters patent in Germany for a wood-pulp grinding machine, but for want of capital sold it to Voelter. J. Macfarlane, of the Canada Paper Company, told me that he first introduced wood to the country in 1874, that he offered some bass-wood to Bruce's of Kinleith—and was laughed at. He finally offered them a farthing per pound over and above the market price for the paper; the pulp was eventually accepted, and proved such a success that the Bruces, very naturally, kept the matter to themselves as long as possible.

The Partington process acquired by the American Sulphite Pulp Company about 1884 was the first to be made use of in the United States of America. It was also conducted in this country by the Kellner-Partington Paper Company, but was, I believe, abandoned a few years ago.

Mitscherlich, who, by the way, was Professor of Chemistry of Munich, began his experiments with the sulphite process about 1876, and later on went to Thodes Mill, near Dresden, and has already been referred to. He started commercially about 1881.

Many lawsuits were fought in respect of the rival patents, which showed very close resemblance in their claims. Behrend, in 1883, disputed the validity of the Mitscherlich patents on the grounds of the priority of Tilghman British patents, and the German Board of Patents concluded that the Mitscherlich process did not differ from that of Tilghman's to entitle it to protection. There were numerous patents in connection with the lining and the digester which we need not refer to in detail.

The treatment by the sulphite process consists first of all in preparing the liquor. This is done by causing the vapour of sul-

phurous acid obtained by burning either "pyrites" (sulphide of iron) or sulphur in ovens, and conveying the vapour up from the bottom to the top of a tower of about 105 feet in height, packed with limestone—a spray of water is introduced at the top and trickles through the limestone. The vapour combines with the water to form sulphurous acid, which acts upon and dissolves the limestone, forming bi-sulphite of lime. In the Ekman process, a stone consisting chiefly of magnesia is used, whereby bi-sulphite of magnesia is produced. The liquor, standing at about 11° Tw., and containing about two-thirds of the sulphurous acid in the free state and one-third in combination with lime, is run into a sulphite digester, which is closely packed with chips of the wood until the liquor just covers over the wood. The lid is put on, steam is introduced until the temperature slowly rises to about 100° C. This causes all the air from the pores of the wood to escape and the solution to take its place, and takes a few hours. The temperature is then increased by the introduction of further steam until it slowly rises to, say, 117° C.; 115° is about the temperature at which chemical action begins to take place; 120° is the maximum temperature above which it is unsafe to go. The temperature, therefore, must be maintained within these limits during the process of boiling. The progress is judged by withdrawing samples of the liquor and examining their colour, sedimentation, and by other means. When the process is complete, the digester is blown off, the pulp washed with hot water, after which it is put into potchers, where it is further washed, and then it is passed through screens for separating out any untreated particles, and collected in the machine in the form of sheets containing 50 per cent. moisture, packed into bales for shipment.

If required in the bleached state, when in the potcher, it is mixed with solution of bleaching powder from 10-20 per cent. of the weight of the material, emptied into "steeping" tanks. When the chlorine is exhausted, the liquor is allowed to drain away, and the bleached product restored to the potchers and treated in the same way as the unbleached product.

Chemical wood pulps now enter into the manufacture of the highest class papers, and such a degree of excellence has been achieved in this that only an expert could tell the difference between a chemical wood fibre paper and an expensive all rag paper.

Soda Process.

The heating is effected either by means of coils or live steam. When the latter, allowance must be made for the amount of condensation. Little makes the statement that the temperature can be raised quickly. I have, however, reason to know that with soft soda aspen the temperature has to be raised slowly and with the utmost care, and also lowered again. The filling of the boiler is similar to that of the sulphite; the full pressure is, however, reached as quickly as possible, and maintained until the end of the treatment, the pressure formerly adopted being from 60 to 75 lbs. per square inch, but latterly it was employed at about 100 lbs. per square inch, and sometimes 110. The time of boiling is from eight to ten hours: as the pressure is increased the strength of the liquor can be somewhat diminished. Unlike the sulphite pulp that obtained by means of the soda process is of a greyish brown colour, whilst the liquor is a darkish brown and of a peculiar odour. This liquor contains the incrusting and resinous matters in combination with the soda as a soluble soap.

Caustic soda, being an expensive chemical, has to be recovered. This is effected by evaporating the liquor down to a thick syrup, after which they are made to flow into a revolving furnace, where they catch on fire, their own organic matters supplying a large amount of heat necessary for the incineration as well as for the evaporation of the weaker liquors. The evaporation is much economised by the adoption of what is known as the triple or quadruple effect evaporator, by means of which the water is removed at the least possible expenditure for fuel. The incinerated ashes as discharged from the furnace appear in greyish and blackish masses in the form of a sort of clinker. This mass, consisting of carbonate of soda mixed with carbon, is "lixiviated" or treated in hot water, whereby the soluble carbonate of soda goes into solution, leaving a black mud of charred and useless matter, from which the liquor is freed by sand filtration. The clear liquor standing at from 16-20° Tw. is heated in iron coppers, and causticised by treatment with caustic lime, whereby the carbonate of soda is converted into caustic soda, and the caustic lime into carbonate of lime or chalk. The chalk forms a sludge at the bottom of the vessel, from which the remainder of the liquor can be removed by filter pressing.

The sludge is pumped into a filter press to remove the liquor still remaining, and water

caused to percolate through to remove the last traces. A clear caustic liquor is ready to be used again in the process of boiling. The process of recovery results in a certain amount of loss of the soda, amounting to about 15 per cent. This has to be made good by the addition of a certain amount of caustic or carbonate of soda. Soda wood pulp is generally of stuff of the nature of sulphite, and though of darker colour, is, as a rule, easier to bleach. Of recent years the soda process has gone to a large extent out of use and has been replaced by the sulphate process. This process consists in treating wood chips in an iron digester with sulphate of soda containing in the first instance a certain amount of caustic. The process is conducted very much like the soda process. It is carried up to the stage of the recovery process in a similar manner; in the soda process, however, the recovered ash consists of carbonate of soda, whereas in the sulphate process the recovered ash consists of sodium sulphide and sulphate of soda. The liquor ready for using again consists of caustic carbonate, sulphide, and sulphate of soda. The process is cheaper than the soda process, because instead of making up for the loss of the soda by the addition of caustic or carbonate, it is made up with sulphate of soda, which is a much cheaper chemical; sulphate passing through the recovery process is reduced by the organic matter to sulphide; a considerable amount of this sulphide is decomposed through the treatment of the wood, giving rise to sulphuretted hydrogen. The gases emanating from a sulphate factory render it necessary to conduct the process in districts where noxious factories are not interfered with.

A great deal of the wood pulp sold as soda pulp is, I am assured by a leading expert, in reality sulphate, and he tells me the proportion appears to be increasing every year. On this subject I am unable to express an opinion, but I am quite certain the British paper-maker secures delivery of chemical pulp capable of being used for the purpose intended.

Possibilities of Wood Products.

Prof. E. Pfuhl has recently published a very interesting book on "Paper Yarn: Its Production, Properties, and Uses." In this book, Prof. Pfuhl gives an account of the progress that has been made in producing yarn from threads prepared by a wet felting of fibres, and the results are most interesting. The raw material, consisting largely of chemical wood pulp, is dealt with in a special manner in the beating engine, so as to reduce the length of the fibres to the necessary extent, and convert the whole into a good felting paper pulp. The pulp is then brought on to a Fourdrinier machine, and a layer of this pulp produced in the ordinary manner, after which it is divided into a number of narrow bands, which bands are twisted by mechanical means, and converted into threads. According to Prof. Pfuhl there are two processes in practical working. One is for the production of a material known as "xyloline" based on the patents of Claviez and Co. In this, the strips of pulp, as they come away from the machine, are wound on to reels, and these reels are then fixed to revolving forks, so that on winding the strip off the reel, it receives the necessary twist, and is mechanically treated otherwise. The material produced yields a strong yarn, and is so cheap that a complete suit of clothes can be sold for 7s. to 10s. It is further stated that it can be washed without being damaged in any way. Silvaline is also produced at Golzern-Grimma on the lines invented by Herr R. Kron. Here paper is divided into strips and subsequently spun into threads, and the machinery is very delicate and beautiful. The first factory was erected in Spain, near Bilbao, and another factory has been erected in Holland. Other factories at Rattimau and Mesterlitz, in Germany, are being erected, and the enterprise is extending to Russia, and there is no doubt that silvaline and xyloline will enter into direct competition with jute, and possibly coarse cotton yarn.

The rapidity of the progress made in this branch of technology is a marvel among modern enterprises, and it is doubtful if, in the history of the nations of the world, any one industry has achieved such a success in comparatively so short a period of time. Probably few realise what an amount of wood pulp the publication of our daily newspapers requires. I may here remark that one London "daily" has recently entered into a contract for the purchase of 10,000 tons of paper per annum for three years, and I think it would be fair to estimate that each day one of our large London daily papers consumes 10 acres of an average forest. Wood pulp owes its wide range of application to the fact that it is a material that can be made to any degree of consistency, from a delicate almost intangible fabric to a dense mass as hard

as metal. It can be dyed to any colour or shade; it can be rendered fire and waterproof; and in the hands of the chemist may be converted into a number of very useful combinations.

Ekman, it is not generally known, succeeded in producing a substance which he called "Dextrone," from sulphite liquors. This substance had special qualities. It could be mixed with glue and precipitated in the form of leather when diluted with water only. It could be used in giving strength to brown papers, in weighting jute, or as a mordant for dyes. It was of the nature of tannin, and yet it had quite distinct properties. Seeing that for every ton of chemical wood pulp produced about a ton of dextrone would be recovered from the liquors, an enormous quantity could be produced if required. This substance was not, I think, manufactured in England after the Ekman works stopped making pulp. Capt. Partington has recently made use of sulphite liquors for watering the roads, and claims to get very excellent results.

Wood pulp is now used for the manufacture of nitro-celluloses. For explosives the pulp has to be of a special nature. It is also used under the name of "Cellulose Wadding," prepared under Feirabend's Patent No. 3061, where it replaced cotton wool for surgical bandages, giving most excellent results. It is also, as Pfuhl reminds us, coming into use in the form of paper in narrow strips, which are afterwards spun into filaments and woven into garments, such as under Kellner-Turq processes and the Silvaline Yarn process. Then, of course, it is used in considerable quantities now for manufacture of artificial silk. According to the Stern process, it is converted into viscose by Cross, Bevan and Beadle's process, and then spun into fine portions through a special solution from which it emerges in the form of filaments. For this product the inventors—all three British by the way—were awarded the Grand Prix at the last Paris Exhibition. They have also received numerous other valuable awards.

In America, where they have no esparto, the printing papers for process blocks can be produced by the aid of aspen, which fibre under the soda process makes a good substitute for esparto. I think, perhaps, not sufficient attention has been paid to the subject of the great differences in the qualities of papers made from wood pulp according to the kind of pulp used and the process adopted. Thus, on the one hand, we were able to produce soft and spongy papers, excellent for filter papers, and, on the other hand, imitation parchments from Mitscherlich pulp, close, transparent, grease-proof, the latter being produced by the aid of the basalt lava beater roll.

Then we have the milk of lime process, whereby bi-sulphite liquor is now produced by passing the fumes of sulphur through milk of lime instead of by allowing it to pass up towers filled with limestone, which is the general system in use in Sweden and Noway. The liquor made by the milk of lime process is identical with that of the ordinary method, but it has the great advantage that it produces a solution of absolute uniformity in strength, a difficult thing with the limestone, but a very important thing for ensuring regularity in the cook.

Digester Linings.

One of the most important things in the history of wood pulp has been the question of digester linings. The Mitscherlich lining in 1894 consisted of tarred pitch to protect the shell, then a layer of thin sheet lead, and on top of this two courses of specially acid-resisting bricks, formed with tongue and groove, cement being used sometimes with the bricks. Some foreign mills place the lining of lead between the two courses of bricks. In a digester heated by indirect heat, a coating of the sulphite of lime can be produced on the surface, which gives a protection for the metal. Jung and Lindig used the coating of double silicate of lime and iron. Kellner took out numerous patents for cements, consisting either of ground slate and silicate of soda, or powdered slate and glass and Portland cement. One of the earliest, and one of the most successful, linings was prepared by Wenzel, consisting of a special cement, for the most part a manufacture of Portland cement and silicate of soda, set in blocks in wooden moulds made to conform to the shape of the digester. Finally, excellent results were obtained by the use of Portland cement alone, which in many cases is reinforced by a facing of special brick or tile, the usual thickness of the cement lining being 4 in. All cement linings are more or less perous when applied, but in use soon fill up with sulphate and sulphite of lime. After numerous years of work, a great many failures, a great many patents, lawsuits, and infringements, a brick has been introduced for lining which answers the purpose. Until a suitable lining could be devised, the sulphite process could not be regarded as a success. As the early

troubles with the linings made it impossible to make pulp cheaply, and the corrosion of the shell contaminated and discoloured the pulp, most of the pulp on the market now as soda pulp is in reality made under the sulphate process, which consists of a liquor containing sodium sulphate, sulphite, carbonate, caustic, which before burning to ash is fortified by the addition of sulphate of soda, the sulphate being reduced to sulphite during the process of recovery. This process is cheap, but the nauseating gases evolved during the process at one time made it a difficult matter, except in out-of-the-way districts.

Methods in the Mill Revolutionised.

I think I might point out that the introduction of wood pulp has had a considerable effect upon the way that mills are constructed nowadays in this country. Before the introduction of wood the raw materials were treated from beginning to end in the mill; now a mill buys wood pulp, which is put direct into the beaters, all the preliminary processes being obviated (except if bleached).

As to the permanency of wood papers, there is still difference of opinion. Mr. Clayton Beadle tells me he would not like to recommend even the very best bleached wood in paper required to be of an absolutely lasting character, but would give the preference to mixtures of cotton and linen. But it should be remembered that every year sees improvements in the treatment of wood, resulting in a more lasting and durable fibre. In course of time we may be compelled to alter our views.

The complete statistics bearing on the subject are much too lengthy and complicated to attempt to read in the limited time at my disposal. They will be found in the Appendix. I may, however, trouble you with one or two figures:—

In 1903, we imported into Great Britain 211,823 tons of chemical dry pulp, of the stated value of £1,842,082. This came chiefly from Sweden and Norway, and only 1,356 tons were sent to us from British Possessions. Of chemical wet pulp we introduced, in 1903, 21,279 tons almost entirely from Sweden and Norway, and value was £82,012. In the same year we imported mechanical dry, 8,268 tons, of the value of £30,192; and of mechanical wet, we imported, in 1903, 336,788 tons, of the value of £752,297.

It is worth noting that Canada supplies us with a by no means insignificant portion of the mechanical wet pulp.

In 1901, Canada sent us 48,551 tons, and in 1908, Canada supplied us with 71,664 tons of the value of £157,918. In this class of pulp, Sweden, in 1903, sent the pulp of the value of, roughly, £101,000; but Norway received £490,949 for the mechanical wet wood pulp sent to us for that year.

According to official figures, British paper makers paid:—In 1903—£1,642,082 for chemical dry pulp; £82,012 for chemical wet; £30,192 for chemical dry, and £752,397 for mechanical wet, being a total of £2,506,583.

I should be very sorry indeed to trespass on any contentious ground or to encroach on political subjects, but without taking any side in the matter I may say that in connection with the fiscal controversy, in the event of a duty being put upon manufactured articles coming into this country, it may be somewhat difficult to classify certain kinds of wood pulp in this connection. It is a rather debateable point as to whether certain classes of wood pulp are manufactured articles or not, or to what extent it may be termed "raw material." I believe Mr. Chamberlain is credited with having been good enough to look upon wood pulp as raw material, but I do not think that this is exactly a subject which is likely to cause paper-makers or pulp producers many sleepless nights in the immediate future, although the time may come when the question will have to be considered from the point of view to which I have alluded.

Appendix I.—Patents.

As will be understood, a very large number of patents have been taken out by those concerned in the development of wood-pulp making, and in importance relating to the same. The following may be taken as covering some of the most important patents from 1867, when Tilghman was granted the initial patent:—

Archbold, George. 1883; manufacture of paper pulp.

——————; manufacture of paper pulp.

Biron, Jean B. 1867; disintegrating wood to form pulp, &c.

Ekman, Carl D. 1882; treating wood.

——————; method of treating wood.

——————; treating fibrous vegetable substances to obtain fibre suitable for paper making.

Francke, David Otto. 1884; manufacture of paper pulp.

Graham, James Anthony. 1883; treating fibrous substances.

Haskell, J. R. 1867; treating and separating vegetable fibres. [Not on sulphite process, but his claim covers first steaming the fibres and then condensing steam by shower of cold liquor so as to force liquor into the wood, as in later patents of Mitscherlich.]

Kellner, Charles. 1886; method of sizing paper to prevent the sulphite and ground pulp from turning yellow. [He precipitates the rosin size with a sulphite salt.]

Minthorn Daniel. 1885; treating vegetable fibre.

Mitscherlich, Alex. 1886; boiling fibres with sulphite.

——— 1886; paper pulp (process for manufacturing).

——— 1889; manufacturing thread from short fibre.

Pictet, R. P. 1885; manufacture of pulp from wood matter.

Pond, Goldsburg H. 1886; manufacture of paper pulp from wood.

——— 1886; machine for manufacture of wood pulp.

——— 1886; manufacture of wood pulp.

Ritter, Eugen Baron, and Carl Kellner. 1885; apparatus and manufacture of cellulose from wood.

——— 1885; progress of manufacturing cellulose.

——— 1886; progress for manufacturing sulphites.

Tilghman, B. C. 1867; treating vegetable substances for making paper pulp.

——— 1869; progress of treating vegetable substances to obtain fibre.

Wheelwright, Charles S., and George E. Marshall. 1884; apparatus for treating wood.

DISCUSSION.

The CHAIRMAN, in opening the discussion, said that the author had given a most interesting history of the manufacture of wood pulp, one of the important and necessary factors in paper-making. Not very long ago paper was produced almost exclusively from rags, from linen rags especially; and perhaps even to-day the best paper was made from that material, except that produced by that most ingenious people, the Japanese. He had seen examples of Japanese paper which excelled anything produced in this country, it being possible to split a sheet of thin Japanese paper into two leaves. The Japanese excelled in so many things, as people in the West had learned within the past few years, that one was not surprised to find that even in paper-making they were, in some respects, in advance of England. In referring to the sources from which wood for pulping purposes was secured, the author had referred to Scandinavia, other parts of Europe, and Canada. In Canada there was one Federal Government and nine or ten provinces, in four of which the forests belonged to the province and not to the Federal Government. In the other provinces, and in that great district which was formerly under the control of the Hudson's Bay Company, or Rupert's Land, the quantity of wood which could be obtained was, he believed, almost without limit. The author had advocated that some means of replanting should be adopted similar to those carried out in Scandinavia; and probably he knew that a Department of Forestry had been established in the country which was giving considerable attention to the subject. But Canada was in a somewhat different position from Scandinavia. There was a very considerable emigration from Scandinavia every year, while on the contrary, in Canada, especially in the North-West, the immigration was very large indeed, so that, to a great extent, it was necessary to clear the forests in order to produce the millions and millions of bushels of wheat which were grown, and came in large quantities to this country. He had no doubt that in a very few years Canada could send wheat in sufficient quantities into the United Kingdom to supply the requirements of the whole of the people of the Mother land. He did not wish to trench upon politics, but he knew that the people of Canada as a whole were most anxious to have the closest possible relations in trade and other respects with the Mother country. It had already given a preference to England, reducing the duties on almost everything imported from this country by one-third compared with foreign countries, and it was anxious to continue that preference. There were already a number of large pulp and paper mills in Canada, but they were few compared with what there would be in a few years; and Canadians would gladly welcome English people with means who would go over and help in producing in larger quantities what he believed was as good wood pulp as was to be obtained from any country. Canada, with its vast forests, which were one of the most important assets of the Dominion, was capable of producing timber and pulp to a greater extent than any country, even the United States. A calculation had been made that in the Province of Quebec alone there were forests equal to 190 or 200 millions of cords of wood. Last year one million cords of wood were exported from Canada to the United States, the advantage of which could have been secured by English people if they had only gone to Canada and erected mills for the production of pulp. Canada desired to be on the most cordial terms with their cousins in the United States, and they happily were so now; but the people of Canada liked to see their friends from the Mother country coming and sharing in the profits, instead of allowing so much to go out of the family, and where they would be welcomed, not as strangers or foreigners, but as their own people. The paper had been most interesting and instructive, and he was sure all the members were under very great obligation to the author for enlightening them on a subject of such importance. Canada also excelled in its water-power over any other country, and the principal falls were all used for industrial purposes. Even hundreds of miles away from what was called civilisation, in the interior of Labrador, pulp companies were at work cutting down the forests and converting the wood into pulp.

Mr. CLAYTON BEADLE thought the author had done justice to the various inventors who had severally and collectively made the industry so great a success. Too much stress had, however, been laid on the work of the first inventor, Tilghman, who only went so far as to make use of sulphurous acid. In addition to the use of that acid, and getting somewhat indifferent results, he foresaw the possibilities of making use of it in conjunction with various bases, and in his specification he protected various bases in conjunction with sulphurous acid; but it was left to the great men who followed him—Franke, Mitscherlich, Kellner-Partington and Flodgvist—by the employment of the same bases, to make it a realisation. He had taken considerable interest in one aspect of the subject, viz., in so far as it affected the manufacture of mechanical wood pulp. On different occasions he had collected information as to the amount of power consumed in reducing various classes of raw material to a condition suitable for the paper machine, which told an important tale. The material which required the least expenditure of power to reduce it to the condition of pulp was chemical pulp, mechanical pulp requiring six, seven, or eight times the amount of power; and in the intermediate class, such products as manilla and jute required double the amount, and linen somewhere about four or five times the amount. There was, therefore, the curious anomaly that the substance which was the very cheapest for the manufacture of

paper required the greatest amount of expenditure of energy for its production. However well provided a country might be with timber suitable for the manufacture of mechanical pulp, even if it was to be had for the asking, it would be impossible to convert the wood into such pulp if the country were not endowed with large water-falls, because the cost of conversion was so enormous as to render it commercially impracticable. For instance, in a country where a power had to be developed by means of coal for steam raising, the cost would be between 20 and 50 times greater than where water-falls were harnessed and used for the purpose. It was a *sine qua non* that the country must not only have the available supplies of timber, but also the water-power for the profitable conversion of wood into pulp; and when all the water-falls were harnessed and made use of for the industry, then the country had reached the end of its tether. That state of affairs would, he thought, be brought about in Norway and Sweden, before many years; but in no part of the world was there a greater amount of water-power available for the conversion of wood into mechanical pulp than in Canada. The prospects in that country were, therefore, very encouraging.

Mr. R. W. SINDALL said he understood, from reliable records, that 38 per cent. of Canada, amounting to 1,400,000 square miles, 12 times the area of Great Britain and Ireland, was timber land, so that there was still plenty of wood in the country. With regard to the important question of replanting, the Canadian Government were waking up to the fact that the forests should be regarded as a kind of Bank, or capital, from which only the interest should be drawn in the shape of mature trees. In earlier years the Government sold the right to cut over a certain area for a given number of years, and obviously it was to the interest of the firm operating in that particular locality to cut out as much timber as they could in the time regardless of those who were to follow. If some system were adopted for licensing the locality he thought the difficulty would be overcome. The Government had now issued strict regulations in regard to the cutting of timber; for example, they would only allow trees of a certain diameter to be cut down, and stringent regulations as to fires, and so on were also laid down, the result being that it was to the interest of a firm to operate in an intelligent and scientific manner. The authorities at the Bureau of Forestry in Quebec were alive to the facts of the case; and one might be sure there would always be plenty of wood in Canada provided only the interest of the Bank, in the shape of mature trees, was drawn. It might be of interest if he stated that out of every ton of wood put into a digester to make chemical wood pulp, 50 per cent. of the weight of the wood went down the drain in the form of useless liquor; so that the energies of chemists and others should be devoted to making some use of the by-products, in that way saving some of the tremendous waste which at present existed. If the Government, or some association of manufacturers established a laboratory in which investigations of that nature could be carried out, vast strides would be made in the manufacture of wood pulp and its allied products. At present very little use was made of the liquor, and the time was fast approaching when the question must be taken in hand. If the Government took some action it would soon be apparent that the manufacture of wood pulp had yet much to accomplish. As a matter of fact, very little was known about wood pulp. Although manufacturers had had 30 years' experience, a paper had yet to be made from wood cellulose showing the lasting quality of paper made from rags. There was no reason why that should not be accomplished, and he hoped, as a result of the paper, greater interest would be taken in the subject than had hitherto been the case. The daily issue of a halfpenny paper, with a circulation of 200,000 copies, consumed no less than 200 trees in the preparation of wood pulp. Fortunately, however, they would re-appear some day in another form; the papers would be burnt, and the carbon in them be given out as carbonic acid gas, which would be absorbed by the trees; so that the paper would go back into the forest as wood, and come back again a few years hence in the form of a newspaper.

Mr. L. GASTER inquired whether the author could give the value of the finished product compared with the value of the raw material, because by that the cost of the energy used in its conversion would be obtained. He thought Mr. Beadle's estimate when he said that to develop power by means of coal would cost from 20 to 50 times more than where the power of waterfalls could be utilised, was somewhat exaggerated. In his experience five or six times was nearer the mark.

Mr. PHILLIPS, in reply, said the question of the finished product was extraneous to the subject under discussion, and would involve a paper almost as long as the one he has given.

The CHAIRMAN, in proposing a hearty vote of thanks to the author for his interesting paper, said he thought a great and good work was being done by the Society in encouraging gentlemen like Mr. Phillips to read papers on subjects of such universal interest.

The resolution having been carried unanimously, Mr. Phillips briefly acknowledged the compliment, and thanked Lord Strathcona for his kindness in taking the chair.

AUSTRALIAN LABOUR COLONIES.*

The various States of the Commonwealth, in their eagerness to attract an agricultural population, are offering every facility for intending settlers, especially those desirous of forming communities based on the co-operative principle. In New South Wales the State Minister for Lands may set apart certain areas for the purpose of establishing labour settlements. A settlement is placed under the control of a Board, which enrols such persons as it may think fit to become members of the settlement; makes regulations concerning the work to be done; apportions the work among the members; and equitably distributes wages, profits, and emoluments after providing for the cost of the maintenance of the members. Any trade or industry may be established by the Board, and the profits apportioned among the enrolled members. A Board is constituted as a corporate body, with perpetual succession and a common seal, and the land is leased to the Board as such, in trust for the members of the settlement, for a period of twenty-eight years, with right of renewal for a like term. When a Board has enrolled such a number of persons as the Minister for Lands may approve, it may apply for monetary assistance on behalf of the members of the settlement. The Minister has power to grant an amount not exceeding £25 for each enrolled member who is the head of a family dependent upon him; £20 for each married person without a family; and £15 for each unmarried person. On the expiration of four years from the commencement of the lease, and at the end of each year following, eight per cent. of the total sum paid to the Board becomes a charge on its revenues, until the total amount advanced, with interest at the rate of four per cent. per annum, has been repaid. In Victoria, areas of land, not exceeding 1,500 acres in extent, may be set apart for the purpose of labour colonies, to be vested in five trustees, appointed by the Governor. For the purpose of aiding the trustees, provision is made whereby persons subscribing to the funds of such a colony may annually elect a committee of management, consisting of four members. The joint body (trustees and committee) is empowered, on a day determined in each case by the State Minister, to admit to such a colony any person who shall be entitled to such benefits as the rules of the colony may prescribe. The trustees and committee of each colony must establish and conduct the same; and they have all the powers and authority necessary to enable them to improve the position of the colony and make it self-supporting. They may establish and maintain any industry they please, and dispose of the proceeds thereof. A subsidy of £2 for every £1 received by the trustees and committee from public and private subscriptions is payable by the State Government. The moneys received being disbursed in the payment of allowances for work to persons employed in the colony; in the construction and maintenance of necessary buildings; and in purchasing provisions, clothing, building materials, stock, seed, and agricultural implements. In Queensland, the area granted to a colony, which must not exceed 10,000 acres in extent, is vested in five trustees, who are empowered to establish and manage any trade or industry. A subsidy not exceeding £1,000, either conditionally or otherwise, may be granted to a labour colony from Parliamentary appropriations for such purposes. In Victoria, special facilities are afforded for the establishment of village settlements, a sum of £67,379 having already been granted in aid of those which have been formed. The area occupied comprises 57,588 acres, and improvements to the value of £254,955 have been effected. The number of settlers actually residing on the 30th June, 1904, was 1,758, and the number not residing, but improving their holdings, 133, making a total of 1,891 in occupation. The number of persons, including wives and children, residing on the date indicated was 8,536. In Queensland, special provision is made by law for the settlement of little communities, so that settlers may live together in townships for mutual convenience, on allotments not exceeding one acre in extent, and with farms of 80 acres in close proximity to their residences. The freehold of these farms may be secured generally on the same terms as those upon which agricultural farms not exceeding 160 acres in area may be acquired, with the additional privileges that residence on an allotment in the township is held to be equivalent to residence on the farm, and one-fifth of the required improvements may be made on the allotment. Ample provision for the establishment of village settlements is also made in South Australia and in Western Australia, where there is an abundance of land well adapted for farming and orchard purposes.

* Communicated by Mr. John Plummer, of Sydney, New South Wales.

TUSCAN OLIVE OIL.

According to the Acting British Consul at Leghorn, the last oil crop has not come up to the expectations entertained during the early part of last year. The yield of oil may be safely put at less than half a full crop, possibly not much more than one-third. Some of the chief producing districts, such as Calci, Montemagno, and Lungomonte, in the province of Pisa, famed for the high quality of their produce, have had but a bare fraction of a crop. The olive-growing districts of the adjoining province of Lucca have been much more favoured in this respect, and, indeed, the bulk of this season's crop has come from this source. On the other hand, a favourable circumstance has been the almost complete absence of the olive fly, hence the fruit has been gathered in general in perfectly sound condition, and oil of choice quality has been obtained, such as fully to maintain the supremacy of Tuscany over all other oil-producing centres. Riviera and Apulia oils are considered to come next to Tuscan in order of merit, though a

good way behind. The lower cost of these oils causes them to be preferred to Tuscan in some markets where price and not quality is the chief consideration. The Nice olive oil trade is based chiefly upon Apulian (Bari) oil. French sardine packers in general make use of Bari oil in their trade, and when the sardine fishery is good, buy large quantities of it. The cheaper brands of sardines, find Bari oil too expensive, and resort to the inferior growth of Tunis. It used not to be so in former years. Up to the time of the Franco-German War French buyers habitually bought largely in Tuscany, and especially oil of the highest quality, for which they paid liberal prices. But from that period dates a declension in the demand, until, at the present time, French buyers have become conspicuous by their absence. Cheapness has become the characteristic of the French market in the present day. Notwithstanding these adverse circumstances, Tuscan, or, as it is often called, "Lucca" olive oil, still holds its own in the markets where high quality is appreciated. A lower standard of value has been established, but still it commands from 20 to 25 per cent. more in value than Riviera or Bari oils. The lower cost of the latter leads to their being used often to blend with the cheaper sorts of Tuscan oil, the compound no doubt passing as "Lucca oil." Shippers of repute, with a well-established trade, and whose brand is accepted as a guarantee of quality, will not resort to this practice. But the case is different with those less favourably situated who are compelled to compete for orders in the open market, which generally means that the lowest price secures the business. In these cases the quality must of necessity be made to suit the price, and hence the necessity of resorting to "blending." Exports of Tuscan olive oil to the United States, of late years, have shown progressive expansion, notwithstanding the heavy customs duty levied in that country, and the competition of the home-grown article. As to the latter it may be observed that, in the judgment of connoisseurs, it can never compete with the produce of Tuscany in regard to quality. The flavour and delicacy of the latter are entirely wanting in the growth of California. This is not surprising, seeing that the climatic conditions of the two regions are so different. Latitude has great influence upon the fruit of the olive tree. Olive oil grown in sub-tropical climates is characteristic of its own, amongst which may be noted the absence of any pleasant flavour, less fluidity than the growth of temperate localities, and a liability to turn rancid very rapidly. Even the relative proportions of the various constituents of olive oil vary very greatly in the two cases. Now Tuscany has a distinctly temperate climate, but it may be remarked that the olive growing districts of California are situated in the same latitude as Tunis and Morocco. In the last two countries the olive is very largely cultivated, but its produce ranks very low in the scale of quality. The demand from the English market, on the other hand, keeps stationary at best. There seems to be a greater appreciation in America of olive oil of fine quality than in England, where there is rather a prejudice against its use as an article of food, except perhaps, amongst the travelled classes. Ignorance of the great dietetic value and wholesomeness of fine olive oil can alone explain why it should be so. Italian medical authorities, as well as those of other countries, who have investigated the subject, pronounce olive oil, when pure and free from taint or rancidity, to be quite as nourishing as, and more wholesome and easily digested than any other form of fat, whether of animal or vegetable origin.

CARE OF THE AGED IN FRANCE.

For more than half a century the French Government has been experimenting with schemes for establishing old age pensions, the first Act having been passed on June 18th, 1850. The plan then tried was not profitable, for Government allowed investors 5 per cent., which was more than it could itself get, and the rate of interest had to be reduced. Shortly after the war with Germany, in 1873, the number of depositors had greatly increased, and in 1882 there was a deficit of about £1,680,000. To make up this the Government in 1884 made over to the Caisse des Rétraites a sum of about £11,300,000 on Government stock, the interest on which, with a small annual grant, amounting in all to about £500,000 would, it was calculated, meet past and present losses, and in 1895 the Act at present in force was passed, but the question is still one that gives the Minister of Finance much anxiety, and it is not unlikely that some future change will be made. At the present time deposits are received from any person regardless of age, but the amount may not exceed £20 in the course of a year. An account may be opened, says the American Consul-General at Paris, for a child of three years of age; a married woman may deposit money without her husband's consent. At any age between 50 and 65, or earlier in case of permanent disability to work, the depositor may claim his annuity, which is calculated according to the amount of his deposit and interest, and the probabilities of life, but the annuity may not exceed £48. In rural districts the tax-gatherer is empowered to receive deposits, and in many factories a certain percentage is deducted from the wages and paid to the Caisse in the workman's name. A branch of the Caisse may be founded in any town or village, with the permission of the prefect of the Department, and there are about 2,300 of such branches, with nearly 340,000 depositors. There are several large institutions for the care of the indigent aged. Some of these are free and at others a certain charge is made for board and lodging. The free ones are—Bicetre (for men only, including 640 lunatics and 200 idiot or epileptic children), 2,664 beds; Salpetrière (for women), 3,891 beds; Incurables, (men and women), 2,147 beds; Brevannes (incurables), 100 beds; Hospice Lenoir (over 70 years of age or incurable), 142

beds; Brezin (a private foundation for persons in the iron trade only), 330 beds. There is an institution known as the "Ménages," at Issy, near Paris, for widowers, widows, or married couples, of whom both are over sixty-five years of age who have been married at least fifty years. Several persons pay £10 a year for board and lodging, married couples £12 each, including separate bedrooms. There is accommodation for 1,461 inmates. At the La Rochefoucauld Hospital a charge is also made of £10 for old people who are in tolerably good health, and £12 10s. for those who have lost the use of a limb. There are many small institutions founded by private persons for old officials at some of which the charge is as high as £10 a year. Some religious orders still shelter a few aged persons, either gratuitously or at a small sum per annum.

THE MINERAL RESOURCES OF CUBA.

The minerals most abundant in Cuba are asphalt, copper, iron, and manganese. Of asphalt, there are rich beds to be found in the provinces of Havana and Pinar del Rio. In Havana province are the mines known as Jesus del Potose and Santa Rosa, situated a little more than a mile to the south of Campo Florido. The Angela Elmira mine at Bejucal, in the province of Pinar del Rio, and the Rodas Concepcion and Magdalena mines are situated at the inner end of the Bay of Marial. At Bahia Honda the Santa Elena mine has a reputation for excellent asphalt; so has the Union mine at Guanajay. In Sancti Spiritus are several asphalt mines. The ones best known are the Poza Colorado and Amparo mines. According to the International Bureau of the American Republics, considerable quantities of asphalt have been exported from Cuba, and as its quality is well spoken of, an increase in exports is anticipated. There is scarcely any metalliferous locality in Cuba where copper is not found in greater or less quantity. In Pinar del Rio mention should be made of the Buenas Aguas, Recompensa, Unión, Caridád, and the Cuba Western copper mines. In Havana province are the old mines of Bacuranas, and others at Jaruco and Minas. In Matanzas province a number of copper mines have been located. In Santa Clara Province valuable beds of copper have been found near Ciénfuegos and Santa Clara city. The most important of the old mines are those known as San Fernando and Santa Rosa from which excellent ore has been taken. In Puerto Principe province are the mines of Bayatabo between the cities Puerto Principe and Nuevitas, also the Marion, the San Antonio del Cerro, and the Cubillas mines. In all these mines the prevailing ore was carbonate of copper, the extraction of which was found comparatively easy because it is found at no great depth. The most important province, however, for copper mining is Santiago de Cuba. The town of Cobra is built on very extensive beds of copper ore, which is also found at Bayamo, Sierra Maestra, Las Tunas, Holguin, and Jiguani. Competition from the mines of Chile and Rio Tinto, as well as those in the region of Lake Superior, has acted as a drawback to the copper mining industry of Cuba, particularly as low grade ore has never been handled successfully there. Iron and manganese mines are of most importance at present by reason of their being worked regularly and on a large scale in the province of Santiago de Cuba. In the province of Santa Clara several gold mines of more or less importance are said to have been located, the most promising perhaps being the Meloneros mine, near the village of Guaracabuya, in the district of Placetas. In the district of Holguin, old gold claims have also been reapplied for, but nothing can be definitely stated as to the cause of their previous abandoment, nor in fact, as to date of their working which, by some, is said to be as far back as the time of the aborigines. The only marble of importance is that which is found n the two mountains, east and west of Nuera Gerona, on the north coast of the Isle of Pines. The marble is of good quality, ranging from a good white statuary stone through various shades of blue veined to dark grey. Specimens with pinkish tints are also found. Some of the marble is reported by experts to be suitable for the finest statuary, the colour being of the purest white. Other varieties of different hues are suitable for ornamentation and art, and they cake on a good polish. The stone is free from cracks, and will furnish slabs of any size, the deposits varying from five to twenty-five feet in thickness, and being so situated as to meet all requirements of convenient and economical transportation to points of spipment on the coast. A salt deposit exists near Salinas Point, Isle of Pines. From this point to the third Salinas Point there are large, clear, salt pits, without trees, easy to work, and which increase in width for some distance.

UNITED STATES TRADE-MARK LAW.

The new United States trade mark law came into effect on April 1, 1905, giving the country, according to *Commercial America*, the first satisfactory protection ever afforded for industrial property of this character. It may be regarded as somewhat strange that the United States has not, until this time, had an adequate law of this kind. This is due, however, to the peculiar historical development of the country. The growth of the value of trade marks is a matter of comparatively recent origin, and for a long time there was no demand for any federal law affording protection of trade marks, the State laws being adequate for all practical purposes.

The old trade mark law of 1881 has for years been regarded as more or less unsatisfactory, but it is significant that not until a decision handed down by

the Supreme Court in November of 1903, was the scope of the old law clearly shown. When it was pointed out by this decision that the old law had effect, not in inter-state trade, but only in cases of marks used in foreign commerce and with Indian tribes, it was at once seen that a new law was immediately necessary. Trade marks in the United States have, within the past few years, assumed in many cases very large value, and the fact that there was no law to guarantee the integrity of these values created consternation among the owners of property of this character.

The general opinion concerning the new law is that it is very well framed and that it is well designed to meet the main requirements of legislation of this kind. To foreigners are granted the same privileges which are given to Americans, provided that the Government of the applicant accords similar protection to the citizens of the United States, and also provided that the mark has previously been registered in the country of origin. The general provisions of the law are such as have been shown by recent developments to be the principal requirements for guaranteeing the necessary protection. The registration fee has been reduced to a merely nominal sum.

GENERAL NOTES.

FOREIGN POPULATION OF CHINA.—According to the latest statistics, the number of foreign commercial firms in the principal treaty ports and in the large cities of China open to foreigners was 1,297, and the number of foreigners residing there was 20.560. England heads the list with 420 firms and 5,662 persons; Japan comes next with 361 firms and 5,287 persons. These two countries have three-fifths of all foreign houses in China and more than half of all foreign residents. Germany has 159 firms and 1,658 persons. The United States has only 114 firms but 2,542 persons. France comes fifth with 71 firms and 1,213 persons. That Portugal in the number of Portuguese, 1,930 residents, exceeds even Germany, is accounted for by her possession of Macao; the number of Portuguese firms is only 45. Spain has 39 firms, Russia 34, Italy and Austria 18 each, the Netherlands 15, Denmark 10, Norway 7, Belgium 3, and Sweden 2.

THE COURSE OF PAUPERISM.—A White Paper just issued (60.—II.) brings down the pauperism returns for England and Wales to the end of March last. Dealing first with London, its rate of pauperism, which stood at 27·6 per 1,000 of the population in January, 27·8 in February, and 26·6 in March, 1905, showed throughout the quarter a considerable increase over the rates in the corresponding period of the previous year. At the end of March the ratio per 1,000 inhabitants of indoor paupers was 16·4, which is higher than in any previous year given in the return, that is to 19 since 1865. The ratio per 1,000 of outdoor paupers was 10·2, which is higher than in any year since 1895, when it was 12·8, and the ratio per 1,000 of indoor and outdoor paupers combined was 26·6, which is higher than in any year since 1875, with the one exception of 1895. Taking England and Wales as a whole, the returns show that the ratio of indoor paupers was 7·4, the highest in the Tables, which begin with 1865, and the ratio for 1,000 of outdoor paupers was 16·5, the highest rate since 1898. The total of indoor and outdoor for England and Wales was 23·9, the highest since 1896. Examination of the comparative statement of the number of paupers in receipt of relief on the 25th March, 1905, and the same date in 1904, shows an increase in the Eastern district of the metropolis of 18·4 per cent.; in the counties the greatest increase, 11·5, is in the Eastern district, which contains the union counties of Essex, Suffolk, and Norfolk, with a population of 2,000,644.

SPANISH SALT PRODUCTION. — The salt industry of Spain is daily extending its sphere of operations, and besides supplying domestic wants, estimated at 300,000 tons annually, exports considerable quantities, amounting in 1904 to 350,000 tons, an increase of 58,584 tons over the preceding year. According to the "Diaris de Cadiz," this production admits of a still greater development, if the public authorities help to keep the ground clear of all encumbrances, which must prove fatal to a commodity whose selling price is so low. The industry placed upon a new basis, governed by modern systems and processes, is capable, it is said, of having an era of prosperity never before experienced by it. There are in Spain to-day, 209 concessions of rock-salt works, extending over an area of 6,803 acres, of which number 54 are in operation and 155 are idle. The territory covered by the former is 2 385, by the latter 4,418 acres. Spanish salt production, compared with that of the rest of the world, ranks sixth in importance, being exceeded by that of the United States, England, Germany, France, and Austria-Hungary. So far, Spanish salt has been admitted into the markets of Uruguay, Newfoundland, Russia, Argentina, Sweden, Brazil, France, Cuba, Norway, Belgium, England, the Netherlands, and countries of minor importance, where it is regarded as unequalled for salting and tanning hides. The salt works of Cadiz alone have contributed 63 per cent., or 221,657 tons, to the total exports of 1904, other parts participating to the extent of 128,349 tons. The average production of the sea-salt pans is 300,000 tons, a quantity which could be much increased if modern alterations were made and certain tracts now lying idle were made productive.

MINERAL WEALTH OF CEYLON.—The results of the Ceylon Mineral Survey of 1903-4 have just been published. During the time this survey was under preparation, periodical reports and specimens of the minerals were forwarded to the Imperial Institute. Seven such reports and numerous specimens were received. Various ores of iron, manganese, and copper have been examined, besides thorium and cerium, both of which are used in the making of incandescent gas mantles. Many other minerals were sent, such as graphite, mica, kaolin, asbestos, limestone, and some gem stones. Unfortunately there are no coal deposits, and so the iron and steel industry will not, in all probability, grow up in Ceylon in the near future, neither, in the opinion of Professor Dunstan, will there be much iron ore exported. Of the other minerals, the samples were too small and not obtained from a great enough depth to give adequate information. The survey has discovered a new mineral, which has been called "thorianite." This is also of use in incandescent gas lighting. Thorianite may command in the English market about £30 per cwt. This discovery is not so important as it at first seems, for not more than a few tons of this mineral are likely to be obtained at present. Of course, a careful investigation as to the distribution and quantity of thorium and allied minerals in Ceylon is still being proceeded with.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

MAY 24.—"Modern Lightning Conductors." By KILLINGWORTH HEDGES, M.Inst.C.E., Hon. Sec. to the Lightning Research Committee. J. GAVEY, C.B., Engineer-in-Chief to the Post Office, will preside.

COLONIAL SECTION.

Tuesday, at 4.30 o'clock:—

MAY 23.—"The Cape to Cairo Railway." By SIR CHARLES H. T. METCALFE, Bart., M.Inst.C.E. The DUKE of MARLBOROUGH, K.G., will preside.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

HENRY WILLOCK RAVENSHAW, Assoc. M.Inst.C.E., Mem.Fed.Inst.Min.Eng., "The Uses of Electricity in Mines." Two Lectures.

LECTURE II.—MAY 22.—Alternating and direct currents — Precautions — Enclosed motors — Home Office rules—Costs—Typical and historical plants described.

The lecture will be illustrated by lantern slides.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MAY 22...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Mr. Henry Willock Ravenshaw, "The Uses of Electricity in Mines." (Lecture II.)
Geographical, University of London, Burlington-gardens, W., 3 p.m. Annual Meeting.
Camera Club, Charing-cross-road, W.C., 8½ p.m. Mrs. French Sheldon, "Experience in the Congo."
Victoria Institute, 8, Adelphi-terrace, W.C., 4½ p.m. Sgr. Cavaliere W. P. Jervis, "Minerals and Metals of the Old Testament."

TUESDAY, MAY 23...SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Colonial Section.) Sir Charles H. T. Metcalfe, "The Cape to Cairo Railway."
Royal Institution, Albemarle-street, W., 5 p.m. Rev. Henry G. Woods, "Velasquez." (Lecture I.)
Medical and Chirurgical, 20, Hanover-square, W., 8½ p.m.
Photographic, 66, Russell-square, W.C., 8 p.m. Dr. T. Holland, "Röngten Rays in Medical Work."
Anthropological, 3, Hanover-square, W., 8½ p.m.
Horticultural, Vincent-square, Westminster, S.W., 3 p.m. Mr. E. R. Holmes, "Medicinal Plants, Old and New."

WEDNESDAY, MAY 24...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Killingworth Hedges, "Modern Lightning Conductors."
Geological, Burlington-house, W., 8 p.m.
National Service League (in the Rooms of the United Service Institution), Whitehall, S.W., 3½ p.m. Lecture by Mr. Diosy.
Royal Society of Literature, 20, Hanover-square, W., 8½ p.m.
Linnean, Burlington-house, W., 3 p.m. Annual Meeting.

THURSDAY, MAY 25...Royal, Burlington-house, W., 4½ p.m.
Antiquaries, Burlington-house, W., 8½ p.m.
Royal Institution, Albemarle-street, W., 5 p.m. Prof. J. A. Fleming, "Electromagnetic Waves." (Lecture I.)
Electrical Engineers (at the HOUSE OF THE SOCIETY OF ARTS), John-street, Adelphi, W.C., 8 p.m. Messrs. W. Duddell and J. E. Taylor, "Wireless Telegraphy Measurements."

FRIDAY, MAY 26...Royal Institution, Albemarle-street, W., 9 p.m. Prof. J. W. Brühl, "The Development of Spectro-Chemistry."
Botanic, Inner Circle, Regent's-park, N.W., 4 p.m.
Clinical, 20, Hanover-square, W., 8½ p.m. Annual Meeting.
Physical, National Physical Laboratory, Bushy-house, Teddington. 1. Dr. Harker, "The Specific Heat of Iron at High Temperatures." 2. Mr. Campbell, "The Measurement of Small Inductances." 3. Mr. Selby, "Two New Optical Benches."
National Service League (at the HOUSE OF THE SOCIETY OF ARTS), John-street, Adelphi, W.C., 8 p.m. Dr. Emil Reich, "The Importance of National Military Training from the Historical Standpoint."

SATURDAY, MAY 27...Royal Institution, Albemarle-street, W., 3 p.m. Mr. J. G. Frazer, "The Evolution of the Kingship in Early Society." (Lecture II.)

Journal of the Society of Arts.

No. 2,740. VOL. LIII.

FRIDAY, MAY 26, 1905.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

NOTICES.

CANTOR LECTURES.

On Monday evening, 22nd inst., Mr. H. W. RAVENSHAW delivered the second and last lecture of his Course on "The Uses of Electricity in Mines."

A vote of thanks to the lecturer was passed unanimously on the motion of the Chairman (Professor Ayrton, F.R.S.).

The lectures will be published in the *Journal* during the summer recess.

COLONIAL SECTION.

Owing to illness, SIR CHARLES METCALFE was unable to read his paper on "The Cape to Cairo Railway," on Tuesday, 23rd inst., and the meeting of the Section announced for that date was, therefore, unavoidably postponed.

CONVERSAZIONE.

The Society's Conversazione this year will take place at the Royal Botanic Gardens, Regent's-park, on Tuesday evening, July 4, from 9 to 12 p.m.

The programme of arrangements will be announced in future numbers of the *Journal*.

COVERS FOR JOURNAL.

For the convenience of members wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1s. 6d. each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

TWENTY-SECOND ORDINARY MEETING.

Wednesday, May 24, 1905; JOHN GAVEY, C.B., Engineer-in-Chief and Electrician to the General Post Office, in the chair.

The following candidates were proposed for election as members of the Society:—

Evans, B. P., The Schools, Treharris R.S.O., Glamorgan.
Sanford, Miss S. Ellen, The Holme, Clifton Hampden, Abingdon.
Thoresby, Frederick, 1, Queen Victoria-street, E.C.

The following candidates were ballotted for and duly elected members of the Society:—

Bodie, Samuel Murphy, D.Sc., Macduff, N.B.
Drury, Henry George, M.V.O., St. Oswald's, Downs-road, Clapton, N.E.
Eldred, Byron E., 208, Fifth-avenue, New York City, U.S.A.
Garside, Alfred B., 1b, Dennington-park-mansions, West Hampstead, N.W.
Harvey, Frank E., British India Marine Service Club, Hastings-street, Calcutta, India.
Moore, Miss Esther M., 4, Bath-road, Bedford-park, Chiswick, W.
Noble, Mrs. G. J. W., 47, South-street, Park-lane, W.
Peattie, M. M. A., 35, High-street, Oxford.
Playter, Franklin, 6, Beacon-street, Boston, Massachusetts, U.S.A.
Short, Ernest Angelo, care of Messrs. H. S. King and Co., 9, Pall-mall, S.W.
Smith-Rewse, Colonel Henry Whistler, R.E., C.V.O., Brompton-barracks, Chatham.
West, Chas. A. W., P.O.A. Kafferstadt, Harrismith District, Orange River Colony, South Africa.
Whitehead, Ernest William, Twyneham, Queen's-road, Wimbledon.

The paper read was—

MODERN LIGHTNING CONDUCTORS.

By Killingworth Hedges, M.Inst.C.E.,
Hon. Secretary of the Lightning Research Committee.

The last time the question was brought before the Society of Arts was in 1888, when Sir Oliver Lodge made it the subject of his "Dr. Mann lectures."

I greatly appreciate the honour of being asked to follow such a distinguished predecessor, and to put before you this evening some of the more recent work in connection with this rather neglected branch of electrical science. The study of atmospheric electricity dates from very early times; it is doubtful whether the art of protection from lightning was known to the Egyptians,* but the Greeks and Romans are reported to have drawn fire from the sky, Tullus Hostilius is said to have perished in a sacred experiment of this kind; and Cicero, in his oration against Catiline, drew attention to the bad omen to Rome that was caused by the gilded figure of Romulus being destroyed by lightning. The well-known Capitoline Wolf still bears traces of the damage. It is generally supposed that Divisch, a learned priest, erected the first lightning conductor in Europe at Prendiz, Bohemia, in 1754; the rod was said to have been 130 feet high, and although he was patronised by the Emperor and Empress Francis Stephen and Maria Theresa, it had to be taken down a year later, as it was supposed to have occasioned a terrible drought. It is not likely that Franklin had heard of Divisch, and although it was due to a communication from Mr. Thomas Hopkinson, an American gentleman, in 1747, that his attention was turned to the matter, he is universally acclaimed as the inventor of the lightning rod which was made known in 1752, and which the European *savants* explained in accordance with scientific theories then current, as a conductor of a supposed "electric fluid" darting from the clouds to earth.

When the British Association met in Bath in September, 1888, Professor G. F. Fitzgerald, who was President of Section A, directed world-wide attention to the discoveries of Hertz, and hailed them as conclusive proof of the truth of Clerk Maxwell's theory of light. The next day Sir Oliver Lodge read a paper on "Measurement of Electro-Magnetic Wave Length," and the author stated that during his experiments on lightning conductors, which he mentioned in his lecture in March at the Society of Arts, as "The Experiment of the Recoil Kick," he hit on an arrangement of measuring the æther-wave lengths in a manner quite independent of that of Hertz, whose experiments were thus confirmed. At the same meeting a joint discussion of Sections A and G was held on lightning conductors.

If I remember rightly, Sir William (then Mr.) Preece opened the discussion by saying that it was a most remarkable thing that if one wanted to know much about atmospheric electricity one had to go back to the works of Benjamin Franklin, 140 years ago. Up to the year 1881 there was not even a code of rules in the United Kingdom to guide people in protecting their buildings from the destructive effects of atmospheric electricity. To the efforts of the British Association we owe the first set of rules, established by a conference of various societies which was formed in 1878 and brought forward their report, known as that of the "Lightning Rod Conference," at the York meeting in 1881.

The history of the art since then has been one of stagnation. Distinguished scientists like Sir Oliver Lodge here, and others in Germany, have put forward their views from time to time, but still we see conductors erected in a manner which can be shown both by laboratory experiments and by actual reference to lightning strokes to be a source of danger instead of acting as safeguards to the buildings; also the misleading belief of an area of protection in the case of the erection of an isolated rod, for instance, on a church tower, while the rest of the building has no conductor, and, what is more important, no metallic connection to earth.

Interest has been again revived, first in Germany by the Electrotechnische Verein, of Berlin, which after much discussion published on July 21, 1901, a set of rules and recommendations for the protection of buildings; and in this country we have the Lightning Research Committee, organised early in the same year jointly by the Royal Institute of British Architects and the Surveyors' Institution, and with the approval of the Royal Society and the Meteorological Society. Members of all these institutions were represented on the committee.

A notice setting forth the existence and requirements of the Committee was issued to the Press, and appeared in all the technical journals interested, and in more than a

* Brugsch suggests that the grooves on pylon towers were used for masts designed to protect Egyptian temples.

hundred representative newspapers in London and the provinces.

An immediate response to the Committee's appeal for observers was received from 225 persons, distributed throughout the United Kingdom as follows:—

Buckinghamshire	3	Lincolnshire	3
Berkshire	2	Middlesex	9
Cambridgeshire	3	Northamptonshire	3
Cornwall	7	Northumberland	4
Cheshire	10	Norfolk	4
Derbyshire	2	Nottinghamshire	1
Durham	6	Rutland	1
Devon	7	Sussex	11
Dorsetshire	2	Surrey	11
Essex	6	Suffolk	5
Gloucestershire	7	Scotland	12
Hertfordshire	1	Staffordshire	6
Hampshire	4	Somersetshire	4
Herefordshire	2	Shropshire	2
Isle of Wight	2	Wales	14
Ireland	5	Warwickshire	5
Kent	15	Worcestershire	2
London	22	Westmoreland	1
Lancashire	12	Yorkshire	14

By the kind assistance of the Secretary of the Institution of Electrical Engineers copies of the Committee's memorandum and schedule of questions were sent to some 400 members of that institution residing in the Colonies, in India and in foreign countries. As a result some interesting records were received, also from the United States.

Through the influence of Mr. J. Gavey, engineer-in-chief to the General Post Office, the various district engineers of the Post Office were enlisted as observers. The Committee desire to acknowledge their special indebtedness to these gentlemen for a number of admirably recorded occurrences, which have been found of much value in their investigations.

The War Office, the Home Office, the Trinity House Corporation, and the United States Department of Agriculture, have also furnished the Committee with particulars of damage caused by lightning to buildings under their control.

The services of a press-cutting agency were engaged to supply the Committee with current newspaper notices of buildings that had suffered from lightning-stroke in thunderstorms. Between four and five hundred such notices reached the Committee during the years 1901-4; and in neighbourhoods not represented by the official observers application was immediately made for particulars to the owners or occupiers of the property affected, or to members of the Royal Institute of British Architects or of the Surveyors' Institution residing in their vicinity.

"It was decided after the first year to confine the Committee's investigation to buildings which were fitted with conductors, and, following this course, the reports on about 40 protected buildings affected by lightning have been summarised by a sub-committee, and the report of the general Committee states that as far as they are able to judge from the newspaper reports which have reached them, the number of reported cases of buildings damaged by lightning in Great Britain during the three years 1901-4 amounted to over five hundred. Altogether the Committee have had before them detailed reports from their observers of the damage done in 115 cases. Seventy-five cases related to buildings which were without any form of protection. The remaining 40 were provided with what had been considered by those responsible for the buildings as sufficient safeguards in the way of lightning rods. While taking due account of the lessons to be learnt from the action of lightning on unprotected buildings which have been injured, the Committee have deemed it unnecessary for the purposes of this report to go into the details of these cases. A selection, however, has been made from the reports of 'protected' cases, and these will be found summarised and put into tabular form in Appendix A, with observations in some instances of the conditions which appear to the Committee to have contributed to the failure of the means of protection provided."*

It has been pointed out by Sir Oliver Lodge that lightning discharges are of two distinct characters, which he has named the A and the B flashes respectively. The A flash is of the simple type which arises when an electrically charged cloud approaches the surface of the earth without an intermediate cloud intervening, and under these conditions the ordinary type of lightning conductor acts in two ways; first, by silent discharge; and secondly, by absorbing the energy of a disruptive discharge. In the second type, B, where another cloud intervenes between the cloud carrying the primary charge and the earth, the two

* Selections of the illustrations forwarded by the Committee's observers on protected and unprotected buildings have been reproduced by the author in a book entitled, "Modern Lightning Conductors." London: Crosby, Lockwood, and Son.

clouds practically form a condenser; and when a discharge takes place from the first into the second, the free charge on the earth side of the lower cloud is suddenly relieved, and the disruptive discharge from the latter to the earth takes such an erratic course that no series of lightning conductors of the hitherto recognised type suffice to protect the building.

On the 28th May last a demonstration of the action of A and B flashes respectively was given by Sir Oliver Lodge before members of the committee and others interested in these researches. A thin sheet of metal mounted on non-conducting standards represented the cloud, which was charged at will from a Leyden jar. The "cloud" was so arranged that the model lightning conductors could have their points brought nearer to or further from its under-surface by shifting their positions on the table. Conductors of copper, iron, and wet string were experimented with. The disruptive discharge to the copper proved to be by far the loudest and most intense of the three. The iron took the flash with less noise, the wet string with hardly any; yet when the discharge passed through it the other and apparently better conductors were not affected. The experiments tended to demonstrate that iron is in many situations a very useful material for lightning rods, as the effective energy of a flash of lightning is rapidly dissipated in iron. This metal, however, unfortunately, oxidises rapidly in towns and smoky districts, and the use of copper is still recommended for main conductors in relatively inaccessible positions as a material for lightning rods.

In Germany two kinds of strokes have been recognised for some time, one as Zündenden ("fire causing"), probably analogous to what Sir Oliver Lodge terms the B stroke, while the other, known under the name of Kalten ("not causing fire"), is the ordinary A flash.

The Committee remark that it is probable that, with few exceptions, buildings in this country are not in reality efficiently protected against the effects of a B flash, although in many cases the lightning conductors may be said to have at least partially fulfilled their purpose by carrying off the more violent portion of a discharge, and without them greater damage would have occurred in many of the cases reported.

Some of these observations throw a very interesting light on the effects due to the oscillatory character of lightning discharges. For instance, a discharge takes place over a lightning rod which may be in contact with, or approach closely to, the metallic portions of a roof. Powerful electrical oscillations are set up in the latter conductors, and dangerously high electrical pressure may be generated on the distant ends of these conductors. If at these points they were connected to earth the pressure would be relieved and the discharge harmlessly dissipated. Without this safe path the discharge may break away into the down pipes, or may pierce the roof to reach internal conductors. Cases which appear to indicate successive or simultaneous flashes may be due to a single flash setting up these oscillations.

In some cases the damage done to a building by an A flash is not necessarily due to the primary discharge. A lateral discharge occasionally occurs, which frequently causes minor, though in some cases serious, damage, owing to falling materials.

Many of the reports of damage to unprotected buildings show that the lightning discharge followed the path of wire ropes, metallic pipes, and other conductors, and that the damage to the structure occurred at the breaks in continuity at the upper and lower terminals respectively.

It may be considered that a lightning conductor of the ordinary type, if properly constructed, affords an undefined area of protection against A flashes; but it cannot be said to have any protective area against B flashes.

Absolute protection of the whole of a building could only be assured by enclosing the whole structure in a system of wirework—a contrivance, in fact, of the nature of a bird-cage. This should be well connected at various points to earth, as nearly all buildings have gas and water pipes and other metallic conductors in their interiors which are likewise earthed. For structures intended for the manufacture or storage of gunpowder and other explosives, the adoption of this bird-cage protection would be justified on the score alone of public safety. Architectural considerations prevent the adoption of such a method in its entirety for ordinary buildings. There is no doubt, however, that practically perfect protection may be assured by a judicious modification of the existing practice of erecting single lightning rods, especially in the case of extensive and lofty buildings that project well above surrounding structures, or that stand isolated in the open country.

There is another name I wish to mention, and that is Colonel the Hon. Arthur Parnell, who read a paper in 1884, before the Royal Institute of British Architects, on the action

of lightning strokes in regard to metals and chimneys of buildings.

I especially draw attention to this paper, as the author was the first to point out the many disasters which occurred to buildings fitted with lightning rods, and that a single metal rod run up the most prominent portion of a building offers a very small protection to the whole structure. He also stated, "That the damage was usually due to mechanical force and not to heat." I quote the following extract :—

"Many persons would doubtless imagine that dry wood-work was more likely to be charred or burnt than to be forcibly rent by a flash of lightning, without a mark of scorching, but the reverse is the case, also in respect to metals, few would believe that this agency was more apt to break or bend metals than to fuse them."

Another point was that in 34 per cent. of the incidents investigated the mechanical force was shown to have been exerted in a more or less upward direction.

The paper referred to was read in what might be termed the dark ages, when fixed opinions were generally held as to what I might term the A. B. C. D. behaviour of lightning—that is, let A represent a building, B the chimney or highest point on the building A, and C the air terminal of the lightning conductor somewhere up above B; we were told that any lightning in the neighbourhood would be attracted to C, and pass through the rod, D, harmlessly to the ground; also it was thought that, besides attracting the flash, the conductor, D, shielded all parts of the building, A, which came into the area of a cone whose base was assumed to have a radius equal to the heighth from the ground. This was stated in the report of the Lightning Rod Conference, page 13, 1882; but it is only fair to say that the Committee, although deeming it sufficiently correct for practical purposes, say "that it cannot always be relied upon."

I am sorry to have to remark that Colonel Parnell's paper did not meet with the attention it deserved, and the general opinion evinced in the discussion was, that it was chimerical. Those who have studied the subject, and who have read the works of Sir Oliver Lodge in this country, and the report of the Berlin Electro-Technical Association published in 1901, take a very different view to the assumptions put forward by the Lightning Rod Conference, and do not agree that lightning is attracted by the conductor, and also consider that the protected area theory first promulgated by the Paris Academy of Sciences in 1823, under the name of the Cone of Charles, and introduced in an amended form by Gay Lussac, is not supported in actual theory, in fact the report of the Lightning Research Committee contains many examples which show that there is no area of protection, and this opinion is put forward by the experts of Germany, Hungary, and Holland, whose reports will be found in the supplement to that of the Lightning Research Committee.

There is a story told of Sir William Thomson (now the distinguished Lord Kelvin), who, after addressing some merchants in Scotland, heard a well-known mill owner remark that it was wrong to oppose the ways of Providence, and much cheaper to insure, and there may be some in this room who hold a similar opinion. I must therefore trespass on their kindness, and ask them to bear with me for a short time, while I go into the important question of: first, as to what we have to guard against; and secondly, as to the best method of protection.

Let us first go back to Benjamin Franklin. Did he understand the action of lightning? I am of opinion that if he had been allowed to have had a free hand when he introduced the lightning rod (which, by-the-bye, originally met with much opposition, especially from the church) the early installations which bore his name would have been put up in a very similar manner to that which the report of the Lightning Research Committee will suggest to be the future standard.

I have here one of the Franklin rods, known at the time as the Jesuit rod.

I believe this is part of, at least, one of the very first lightning conductors erected in this country, as it came from the inside of the dome of St. Paul's Cathedral—I removed it myself in the year 1900—where I think it was placed in 1756. There were three of these iron bars connected to the metal cross—the reason for these joints was to allow the conductor to be shaped to the inside of the upper dome; so far it was run in a fairly good manner, but unfortunately, the ends of these bars passed through the stonework, and then were doubtless continued to the several galleries and finally to the earth; but some time or other these outside rods were removed. Consequently, I discovered that the original protection became a source of danger in that the rods stopped short in the stonework, and had no earth connections. That was no part of Franklin's scheme, who doubtless, had well

thought out the matter, and in using iron conductors he was putting forward the most suitable material, a fact suggested by Hertz, and practically demonstrated by Sir Oliver Lodge.

Most people travel on the continent, but I venture to think very few have noticed that, I might say without exception, the lightning conductors used so freely on the cathedrals and public buildings abroad, are always constructed of iron. There are two reasons for this: one is, that they have never changed from Franklin's original iron rod, and the other is, that practical experience shows that this material is superior to copper. Architects here discarded iron because of the so-called unsightliness of having bars or rods running down places where they were of necessity visible, and rather welcomed the innovation of the copper band or cable, which by degrees has been diverted by the contractors for its erection—I cannot style them electricians—until at the present time, this copper band is run round sharp angles and tucked away into obscure corners, where it is unseen, and also to a large extent, quite useless for the purpose for which it has been erected. Fortunately, you cannot do this with a rod of iron three-quarters of an inch or more in diameter, so the lightning conductors abroad are run as they should be, straight up and down from the spire or roofs to the ground, and they have proved their efficacy. As far back as 1888, Sir Oliver Lodge showed that the old view of lightning protection was as if there was something to be allowed to escape or let down like rain, or as if there was a certain amount of stuff called electrical discharge to be got rid of, and all you had to do was to provide a channel down which it would go, avoiding all other channels, so that it would neglect all other paths and take the easiest one to earth. It was also supposed that the easiest way to get rid of the electricity one did not want was to supply it with the best possible conductor, in fact, the largest one could afford, and the only reason for not using a copper rod a foot thick was that of expense. But it is now known that a copper rod of this area would be dangerous, and a number of iron wires, one-tenth of an inch in diameter, would be much safer. Why is this? Is it that copper, which is one of the best conductors of electricity, is not so suitable for the purpose of protection as iron? The answer is, because of electrical inertia. A copper rod allows the discharge to pass too quickly, and produces a shock of the utmost violence; in fact, experiments were recently shown at the Royal Institute of British Architects where a large copper conductor, which was perfectly earthed, gave out sparks of great intensity, and these, if a lightning discharge was passing, would be quite sufficient to set fire to the building. An iron conductor offers more impedance to the current, and allows it to leak away by damping down the oscillations, so there is less chance of a side flash from an iron than from a copper conductor.

The characteristics of a flash of lightinng which more particularly concern us are:—(1) surging, that is due to the oscillatory character of the spark, which, unlike the currents employed for conveying electricity to a distance for lighting cities or driving tramcars, is a disruptive discharge, sudden and violent, more like the blow of a hammer; (2) self-induction, a property which gives rise to counter force or choking effect, noticeable in straight wires, but which is much more pronounced in coils of wire; (3) side flash, the result of self-induction. A disruptive discharge will often leave what would ordinarily be called an excellent conductor and side flash through the air to other much worse conductors; for instance, the lightning rod may be struck, but instead of following the course provided, a side flash may select its own path through a wall of brick or stone to a neigbouring gas-pipe or bell-wire. The often-quoted example of this danger is the accident at All Saints' Church, Nottingham, about 1870, when the discharge passed from the lightning conductor through a solid wall of masonry, 4½ feet thick, to a gas-pipe. A photograph appeared in one of the magazines a short time ago showing about twenty oxen lying dead along the line of an iron-wire fence, thus practically illustrating the surging effect of a lightning flash which may cause great damage. That these cattle were killed by a side flash from the line of the fence may be inferred from an incident mentioned at the discussion on lightning conductors before the British Association in 1888. A number of horses placed in a row were struck, the first and last of the row being killed and the others not touched by a lightning discharge.

Unquestionably, wire fences as now constructed serve as death-traps to cattle in many countries. The Director of the Iowa, U.S.A., Weather Service, in September, 1898, says:—"These reports show that of the 256 head of live-stock killed by lightning, 118

were found in close contact with wire fences, and also that, as there were no ground wires to the fences, over 44 per cent. of the losses were caused by contact with the wire charged by a lightning stroke, which struck the fence at a considerable distance from the point where the stock was killed."

A later report mentions that a number of deaths have occurred to persons who have been, during a thunderstorm, placing or removing clothes from the wire which takes the place of the clothes-line in the Western States.

I now purpose to show some slides taken from photographs, and plans of buildings which have been submitted to the Lightning Research Committee by their observers; all these buildings have been fitted with lightning conductors, but unfortunately owing to the way they have been arranged they have not altogether shielded the buildings from damage.

The principal causes of the failure of the usual style of lightning-rod as fitted on the buildings investigated, appear to be due to the following: (1) insufficient number of conductor and earth connections; (2) the absence of any system of connecting the metallic portions of the buildings to the lightning conductor, especially the interconnection of the finials, rain-water pipes, and gutters. In the author's opinion the frequent damage by side-flash from the conductors might be lessened by running a horizontal conductor along the ridge, or along the parapets of all the roofs, somewhat after the method which is almost universally adopted in Central Europe.

The lightning strokes may be divided into three classes:—(1) Those where the conductor conveyed a portion of the flash to earth, but the side flash to other unearthed metallic conductors damaged the building; the practice of running the conductor round the projecting masonry, often taking sharp bends, doubtless facilitated the deviation of the current from its direct path to the earth; (2) in several observations a metallic roof of large area received the flash, consequently became highly charged, and the single conductor failed to convey the whole of the stroke, a portion of which took a circuitous path, for instance, through a speaking tube and an electric bell wire; (3) a flash struck the building at two points simultaneously, a lightning conductor taking one part of the stroke, but damage was caused by the other portion selecting an unprotected part of the roof.

Truro (Kea Church).—Wooden spire (88 feet high) covered with copper. Reported by Messrs. J. C. Daubuz and G. H. Fellowes Prynne. Tiling damaged; lead flashings turned back; wall considerably shaken and the face stones fractured. Divided; part going by conductor and part by alternative path formed by copper covering of spire, iron pipe, &c., from which it sparked through parapet wall to lead flashing. Copper tape 1¼ in. by ⅛ in. Good earth. Copper sheathing of spire, rain-water pipe, and copper wire which passed over conductor and near pipe. The rain-water down pipes should have been connected with the roof metals, *i.e.*, to the copper roof and lead flashings, and also to earth. This would have prevented the side flash and consequent damage.

Hampstead, Golders-green.—Convalescent Home, formerly private residence. Reported by Mr. Walter Hall. Small hole made in apex of gable, casement of window damaged; plastering damaged and looking-glass smashed. Copper rope ½ in. and ⅜ in. diameter, and rod ¾ in. Three points. Only one finial point protected; three without conductors. All the finials should have been connected by subsidiary conductors to earth.

Stoerhead Lighthouse.—Metal roof and iron railing around lighthouse. Reported by Mr. J. M. Irvine, Engineer. Wall damaged; bedstead scorched; gutta-percha wires of telephone circuit burned; woodwork set fire to. Part at least took path by speaking tube, telephone wires, and also by bedstead to wires; thence to earth at pole. Copper rod ¾ in. or ⅞ in. diameter. Earth not good. Resistance from ground line 29 ohms. Iron railings; speaking-tube and telephone wires. An isolated building on an eminence. The copper speaking-tube and the iron railing around the lighthouse should have been connected to independent earths.

Rochdale (Stricklands Brewery).—Stone building, tall chimney, iron band round base of chimney. Reported by Mr. H. Frost, Sectional Engineer, P. O. Telegraphs. Chimney cracked 15 feet above shed abutting on stack; portion of rod above chimney broken off. Rod with three prongs. Character of earth unknown. No sufficient data could be obtained to admit of a definite opinion as to cause of damage.

Cambridge (Cavendish Laboratory).—Reported by Mr. W. M. Fawcett, M.A., F.S.A. Displaced tiles; made hole through sill of dormer and fused gas pipe. Struck brass nob on top of lead-covered angle of roof, passed to lead cheek of dormer and to gas pipe. Copper wire rope ⅜ in. diameter on tower. Conductor on tower 36 ft. from point struck. Not stated, but the rod had been recently fixed. Passed by brass nob to iron rod and lead cheek of dormer and gas pipe.

Illustrates the need for earthing all metallic portions on the roof of a building.

Cubbington (Warwickshire).—Workmen's dwellings, school-house, and residence. The lightning spread over the roofs of these low buildings, earthing by the rain-water pipes. The interesting feature of this case is the effect of one portion of the flash, which perforated the brick wall, 1½ ft. thick, of the schoolmistress's house, where the pipe-hook supported the gutter. It made a hole about ½ in. wide, then jumped to a wall on which a small gilt frame was hanging, playing over the gilding, which appeared as if washed off; it then again pierced the wall near the bottom of the frame and escaped by the pipes. The slide is taken from a photograph of the wall-paper.

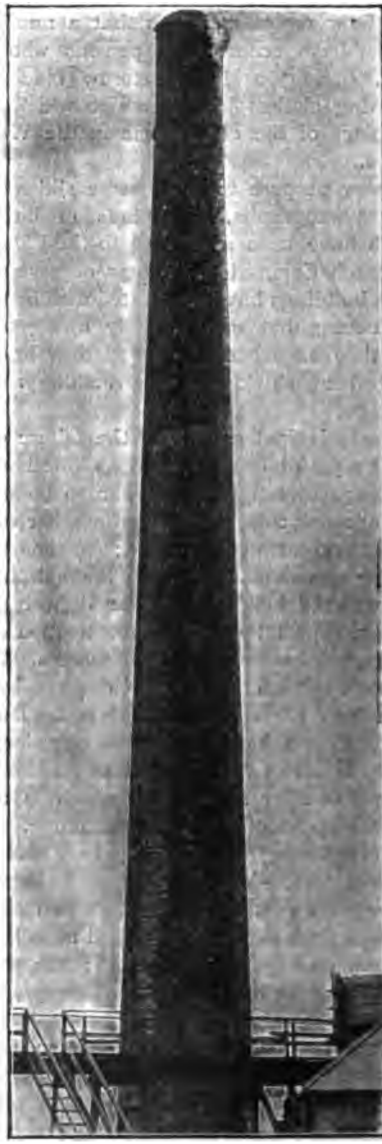
Mark's Tey (St. Andrew's Church) —Tower of oak; wooden spire covered with oak shingles. Reported by Mr. W. Cressall. Displaced weathercock and disturbed some bricks. Probably struck weathercock, and passed to conductor connected therewith. Copper wire rope, ½ in. diameter; single pointed terminal. Beyond displacing weathercock at top, and a few bricks where the rod entered the ground, no damage done; although apparently not efficiently terminated at either end, the rod conveyed the charge safely to earth.

Highgate (St. Michael's Church).—Tower and spire surmounted by stone cross, 145 feet high. Reported by Mr. Walter Hall and Mr. Killingworth Hedges. One arm of stone finial cross broken and displaced; ball of cross shattered; falling stones crashed through roof of nave. Struck arm of cross, then probably passed to conductor. Copper rod, ⅝ in. diameter. Earth. Found to be in connection with the electric light mains A stroke caused similar damage some years ago.

Bedford (St. Paul's Church).—Tower and spire. Reported by Mr. W. P. Goulding, F.S I. Heavy beams inside building slightly displaced, supporting corbels split; main switch of electric light fused. Iron rain-water pipes broken; lead flashings on roof broken and torn away. By conductor from top of spire to lead flat, at bottom of spire, on which conductor lay; then divided, portion finding earth through rain-water pipes, &c. Copper cable ⅝ in. diameter terminated under seat of weathercock at bottom, if spire is laid on the lead flat. Path. Formed by lead roof and rain pipes, &c. A very interesting case. The conductor being in contact with the lead flat violent oscillations were set up, which extended the whole length of the roof; no subsidiary conductors being provided, the discharges took all available paths, some inside and some outside the building.

Walsall (Shire Oak Brewery).—Chimney 70 feet high. Reported by Mr. G. H. Boulter. Bricks displaced at top of chimney, and earth dislodged at bottom of conductor. Struck chimney opposite conductor, and then passed to conductor. Copper tape and rod carried 4 ft. above chimney. Building occupying the highest ground in the neighbourhood. Illustrates fact that lightning conductors on a shaft should terminate at the upper extremity in manner recommended by Committee. (Fig. 1.)

FIG. 1.



THE PATH OF A FLASH DOWN A CHIMNEY WITHOUT A CONDUCTOR, SHOWING DAMAGE.

Maidenhead (Church [of all Saints).—Reported by Arthur Goulding, F.S.I. Cock on finial of tower knocked off the spindle, breaking some tiles in its fall. Finial rod and cock to copper conductor. Finial rod ¾ in. iron 6 ft. above apex of spire; ½ in. wire rope. The cock formed an imperfect upper terminal to the lightning rod; apart from this the rod acted efficiently. (Fig. 2).

FIG. 2.

ALL SAINTS' CHURCH, MAIDENHEAD.

Coatbridge, Lanarkshire (Church).—Tower about 80 feet high, upper half octagonal, carrying eight cone-shaped balusters, one at junction of each angle. Reported by Mr. W. E. A. Knight. Three balusters damaged and part of conductor rod led round tower fused. Roof damaged by falling stones. Struck balusters, then followed circular part of conductor to loop, then to vertical conductor and to earth. Copper rope of seven strands from above balusters to earth. A subsidiary conductor carried around at the base of the balusters and connected to main rod. A conductor on each baluster reaching down to the circular band at the base of the balusters would have prevented all damage.

Isle of Wight (Godshill Church).—The lightning missing the flag-staff, struck the pinnacles and parapet, passing between the latter and the lead flat forming the tower roof, which was uninjured, acted as an explosive inside the tower, destroying the stairs, clock casing, deal panelling (filling in the tower and next to the nave), broke all the windows, dislodged the basin of the font from its pedestal, doing minor injuries inside the building. The walls of the tower three feet thick were forced open at the quoins, and the clock fell (blown some fifty yards from the tower). Reported by Mr. Arthur Goulding, F.S.I. The case is interesting for two distinct reasons. First, that the high flag-staff with metal vane, which certainly was a more salient feature and a better conductor than a stone pinnacle, was untouched; and secondly, although the church had been previously struck in 1778 and in 1897, the insurance companies have not insisted on any system of protection.

Tunbridge Wells (Southborough Vicarage).—Reported by C. H. Strange. Detached building standing on a hill about 400 feet above sea level. The mechanical effect of the discharge was very great; the chimney struck is indicated by dotted lines on the slide. It then blew out the face of the chimney breast on the bedroom below, and finally wrecked the fireplace on the dining-room below. During the same storm a number of the incandescent lamps (unlighted) had their filaments broken.

Possingworth House, Cross-in-Hand (Private dwelling).—Reported by Mr. Killingworth Hedges, M.Inst.C.E. Building struck twice. First case struck and displaced conductor, and also did damage to chimney and stacks. Second case destroyed chimney, damaged roof, and part of the divided flash struck statue not provided with rod. First case main charge probably followed rod. Second case the flash ignored the intermediate chimneys, which were all protected by individual rods, and struck the one unprotected point, which was much lower than the chimney-stacks. Copper tape, 1½ in. Every chimney-stack fitted with a rod. The flash struck the rods on both occasions about three feet below the air terminal. Good earth. The tape conductor was run indirectly to earth, so that a portion of the charge travelled down the wet roof. These two cases can only be reasonably explained on the supposition that the discharges were of the B type, and this hypothesis is supported by the fact that numerous trees in the neighbourhood were struck; an unusual number of lightning rods were provided, although they were not interconnected. It will be noted that the structure did not suffer any internal damage, so that the rods afforded some measure of protection; and if they had been connected by a horizontal conductor, furnished with more direct earth connection, the damage might possibly not have occurred. (Fig. 3.)

FIG. 3.

DIVIDED FLASH, POSSINGWORTH HOUSE, SUSSEX.

FIG. 4.

AINSWORTH MILL, BOLTON.

Bolton (Ainsworth Mill).—Chimney about 60 feet high. Reported by Mr. W. W. Midgley, F.R.Met.Soc. Chimney demolished. Windows of mill broken; gas-pipe fused and gas ignited. The fall of the chimney wrecked the engine-house, and the mass of *débris* was so great as to prevent further investigation. The flash would appear to have taken a path along the interior of the chimney in preference to that furnished by a faulty lightning rod, for it burst out with destructive violence at the base of the chimney, causing the collapse of the whole.

Modern Lightning Conductors.

To carry out the recommendations of Sir Oliver Lodge, who, in his paper read before the Institution of Electrical Engineers in 1889, stated that "sharp bends and roundabout paths to earth should be avoided, and that a lightning conductor detached from a building is safer than one in close contact to it," the author has designed special clamps or holdfasts which project from the wall or position where the conductors are run, and hold them away from the same, and facilitate the cable being strained so as to avoid the projecting masonry. The conductor is then firmly held by a special grip at the end of the clamp, which only requires one screw. The joints used in the system, in order to secure perfect conductivity, are made by pouring solder or pot-metal over the loosely-spliced, previously tinned, conductors, which are laid in a box, that can be used either for two, three, or fourway joints. Similarly, if it is required to connect the cable to a plain point, it is either inserted in a socket or in a box which is fitted with a socket to receive it, and molten solder completes the electrical connection.

Elevation rods are made in a similar way. Here are shown three forms, for either tape or rope. The multiple points are not screwed in, as the threads deteriorate with age, and they are liable to drop. Therefore they are secured to the centre point by means of the sleeve, which has recesses in which the points are secured, and the box is filled with solder. If required to be packed, the points are kept closed together, and afterwards bent to shape. The Continental practice of running a horizontal conductor along the ridges of all the roofs has been adopted by the author in all the important installations he has specified, with the double object of interconnecting the different elevation rods, which are fixed on the higher points, such as the chimney stacks, and also to offer a good path for the lightning, should, as is often the case, side flash take place. From this conductor smaller wires are taken to the rain water guttering, which in its turn is connected to the rain water pipes, and thence to earth. At Westminster Abbey, and on other buildings where the roofs are very long, aigrettes are fixed to the ridges at intervals, the conductors passing through them as shown. Fig. 5 illustrates how a roof, say, of a large church is fitted, the aigrettes themselves, as well as the down conductors, being in contact with the lead of the roofs. Thus it will be seen that the object in view has been, as far as possible, to surround the building with a protective network. The ideal plan advocated by Sir Oliver Lodge would be to encase it with barbed wire. Doubtless this would be very effective, but hardly practicable, on account of repairs to the structure. The author has endeavoured to retain the effective network without sacrificing its utility, and although there are many points for the discharge of the electricity which gathers on the surface of a building during a storm, these are so unobtrusive as to be hardly noticeable by a spectator below.

The above is a description of existing practice, but it is quite possible to shield a building in a very different manner by the use of iron wire; a suitable size is seven strands known as a seven ply galvanised cable about $\frac{3}{8}$th inch diameter. Here is some of the material, and as it is very cheap, one may use a lot of it and more nearly approach the ideal "bird cage" advocated by Clerk Maxwell. If economy is an object, air terminals or elevation rods need not be used, the vertical iron conductor is carried up so as to project above the various chimney stacks and pinnacles or points, and can be opened out so as to present a number of points. The general appearance of a building protected in this manner is shown by the slide which represents a pumping station and chimney shaft. In actual practice the wires which form the cage over the building will hardly be noticed from the ground level. The number of barbs shown in the slide can be modified, in fact where there are many finials or if there is iron cresting, it would only be necessary to have a few points on a horizontal wire which runs along the ridge, and this can be either armoured by twisting round it short pieces of steel wire as shown; the lower legs will keep the conductor away from the roof. A more durable way of holding the conductors is by means of a special device which the author has designed for use in almost every position where stranded wire is employed. You see that it is a triangular, malleable casting, furnished with a spike when used horizontally, the lower legs can be turned over to grip the ridge of the roof or be fastened to the lead flat, and for vertical conductors the same casting does without the spike. A simple and efficient method of joining the cable to the casting is accomplished by a specially designed lead ferrule, which is inserted and closed up

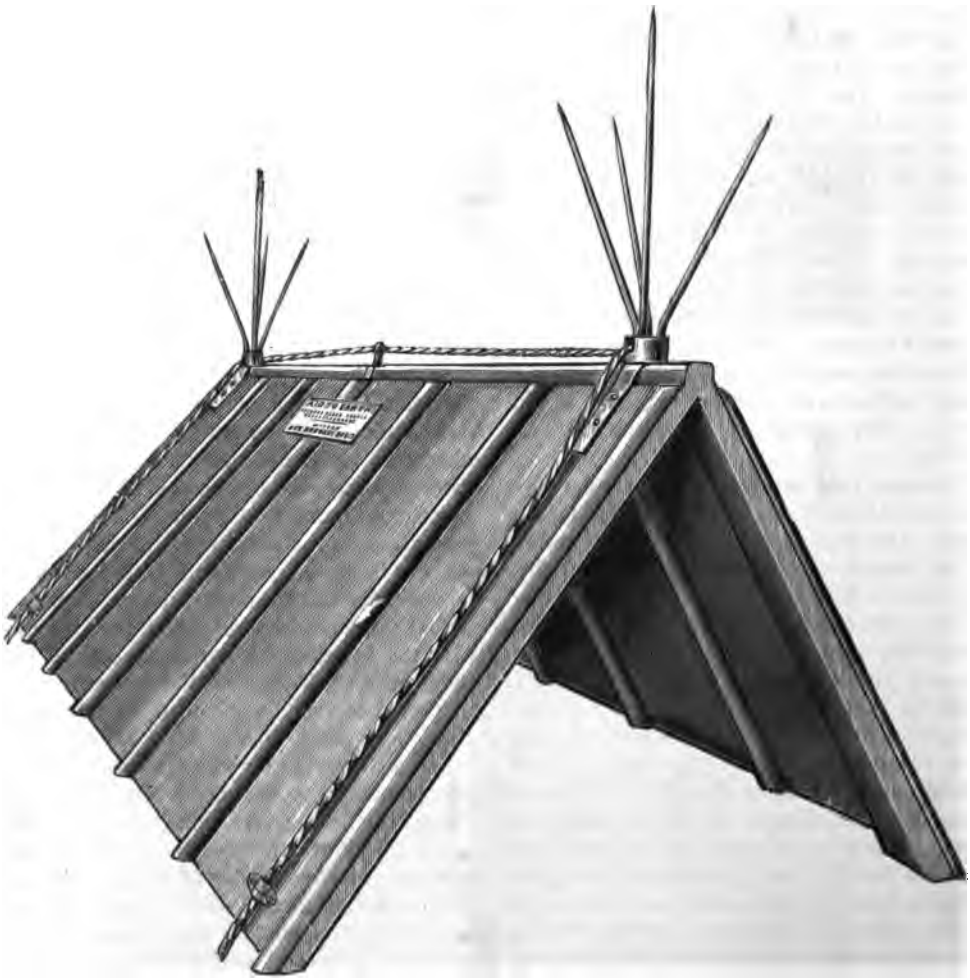
by a tool; it can also easily be removed if the system has to be disconnected.

In all cases where rain-water pipes are used as conductors, care must be taken to bond the joints, so as to ensure good electrical connection, that is if one does not care to risk the cracking of the sockets which form the path of the discharge. There are many ways

CONTINENTAL SYSTEM.

With the exception of Belgium, where the Melsen system of having a network of copper conductors over the buildings connected at the roof to a number of copper rods made up in bundles of eight, and spread out like a feather, is often employed, iron is the material in general use.

FIG. 5.



MODEL OF ROOF OF WESTMINSTER ABBEY, SHOWING AIGRETTES ON RIDGE.

of bonding, here is one which is simple, and can be fitted after the pipes are erected.

Fig. 6 shows the method adopted by the author for the new Royal Horticultural building, Vincent-square, S.W., and Fig. 7, the arrangement of conductors on a private house at Brighton.

In France the standard rod or *tige* is six mètres high, the diameter at the base about 0·060 mètre, tapering to a sharp point; this rod is firmly connected with the iron work of the roof and the iron down conductor is fixed at the base, usually the tige is connected to the horizontal rod which runs along the ridge

FIG. 6.

ROYAL HORTICULTURAL BUILDING: MODIFIED CAGE PROTECTION.

FIG. 7.

MODIFIED CAGE, PROTECTION OF HOUSE.

or round the eaves, being kept away about 18 inches from the roof. The down conductor is sometimes of stranded iron cable, but more often a solid rod three-quarters of an inch to one inch in diameter, bolted together at the joints.

The earth connection is often made by leading the rod into a well. In one form in use in France, surface is obtained by plaiting up galvanised iron strips so as to form a basket which contains a sort of grapnel attached to the conductor, the basket being filled with coke.

The various fittings are shown. The next view is one from a photograph (Fig. 8), and shows the way the conductors are run to protect the Vatican, Rome. The next is from a photograph of the roofs of a hospital at Naples. The two wings are connected by the cable which runs across the intervening space. Thunderstorms are very severe in parts of Germany—the loss annually amounts to £200,000 —consequently the system of protection is much more elaborate than the practice here. In the neighbourhood of Frankfort, I noticed the roof of a factory with twelve projecting air terminals, each not less than twelve feet in height.

The German rules of the Electrotechnische Verein may be summarised as follows:—

"Special attention is drawn to the fact that the conductors of the buildings must be in metallic connection with the earth, and that they ought to go round the building, especially round the top of the roof, and, if possible, on all sides of the roof, and then lead to the ground in the shortest possible way, avoiding all sharp curves. Metallic parts in the building and masses of metal, especially those in contact with the earth and offering large surfaces, are to be connected together as much as possible and to the conductors. In order to decrease the cost, consideration should be given to utilising the pipes upon the building, and all metallic parts should be made use of where possible. Conductors of iron are generally used, and should have a sectional area of not less than 50 square millimètres if interconnected, and not less than 100 square millimètres if unconnected. If the conductors are of copper, half these sections is sufficient. All connections to have a metallic contact surface of not less than 10 square centimètres. Conductors must be repeatedly tested."

Many local boards in Prussia insist upon lightning conductors being fitted on public buildings, such as schools, town halls, hospitals, and churches. The regulations vary with the different local authorities. In Frankfort the municipality have the following:—

"The erection, alteration, and repairs of lightning conductors must be in accordance with the scientific rules now in force. The conductors must be of pure copper, and of not more than seven strands. House owners must have their lightning conductors examined at least every two years, and an examination is also required in the case of the erection of, or alterations or repairs to, a lightning conductor which has been struck. Designs and specifications of proposed erections must be submitted to the local board, and for the accuracy of the same the house owner is responsible."

How to Protect a Building.

Before going into the question of what accessories in the shape of lightning conductors are to be erected, it is necessary to study the disposition of all the external metal work—the material of the roof, the finials, and all ordinary guttering, flushings, rain-water pipes and connections, drain ventilators, telephone, electric and bell wires; having made a rough plan of these, arrange that the conductors are run from the highest points to earth, but in the case of a church, where the vertical conductors arrive at the main roofs, a horizontal conductor must be placed, so that besides being in connection with those from the tower, it runs along the ridges of the roofs, whence it is connected to all salient iron work. From it descend other conductors, which are connected to all the guttering and rain-water pipes; in many cases these can be used as down paths to earth, but it is well in the case of a building of considerable area also to run the branch conductors direct from the roof to the earth.

As regards air terminals, it is not absolutely necessary to let these project much above the highest points; if there are many chimneys or spires, each should have a pointed rod, and for a church or other long roof, aigrettes fitted to the horizontal conductors which run along the ridge are advisable in order to discharge the electricity which will accumulate during a storm all over the building and be collected at many points on the roofs.

Earths.—No rule can be given as to the number required, it greatly depends on the nature of the soil; for instance, a church on the top of a hill on hard limestone would require a great many more earth connections than one in a valley. An earth to be of use must be of low resistance, that is only obtained permanently in moist ground, and if this is not easily obtainable the best way to keep the earth connection damp is to run a small pipe from the nearest rain-water pipe in such a manner that some of the rainfall is diverted

directly to the metal plate which forms the earth.

This portion of the lightning rod has hitherto received the least attention mainly because architects and others have drawn their specifications so loosely. Here is an extract from one recently sent me which referred to some large schools:—"The conductor to be connected at base to a copper earth-plate 3′ 0″ × 3′ 0″ and 1/16 thick, buried 6′ 0″ deep in earth at a distance of not less than 8 yards from the wall at base."

Nothing is said as to where the earth-plate is to be buried, or whether the soil is rock or chalk, the consequence is that one finds earth-plates almost insulated from the ground in dry weather and quite ineffective. The connection between the copper plate and the lightning conductor is also often faulty; the latter often gets rough usage and consequently becomes disconnected from the plate. When asked to test an "earth," I generally pull the conductor, as in several cases I have found it disconnected entirely.

At St. Paul's Cathedral the conductors had been originally laid in a brick sewer which passed round the building, this became unused and was consequently left dry; when I discovered them some were placed inside and others were outside the drain pipes which took the place of the sewer, and were quite insulated and consequently useless. The example is not quite so bad as the one in a northern city where the conductor was insulated in a ginger-beer bottle, which had been duly buried to act as an earth. The cathedral is surrounded by the foundations of the previous structure, which rendered it difficult to make a deep enough hole for a plate earth; this led to the design of the tubular earth, which has now been largely used. This is made in two sizes, and consists of a strong perforated steel pipe, either 1¼ in. or 2 in. diameter, and furnished with a sharp spike, which will cut its way through chalk or gravel. At St. Paul's Cathedral it was easily driven through the broken stone which marks the site of the previous structure, destroyed by lightning long before Benjamin Franklin's discovery of the lightning rod. The end of the tube having been protected by a thick driving-piece, which is screwed on temporarily, it is easily sunk by means of a hammer or mallet, and if there is an obstruction, the pipe is moved by a bar inserted in the holes of the driving-piece. Lengths, connected by a special form of socket, are added until moist ground is reached. The conductor is threaded through the cast-iron top piece, and dropped to the bottom of the tube, which is filled with finely-

THE SYSTEM OF LIGHTNING CONDUCTORS ON THE VATICAN, ROME.

granulated charcoal. An electrical joint between the conductor and the cast-iron top is now made by pouring lead or pot-metal into the socket through which the conductor passes, and tamping it in the same way as if

TUBULAR EARTH, SHOWING AUTOMATIC WATERING BY RAIN-WATER PIPE.

it were the joint of a water-pipe. The earth connection is now complete; but, in order to make it permanent, and to keep the moistness which is essential, a small piece of pipe is led from the special hole in the casting either to the nearest rain-water pipe, as shown in Fig. 9, or, if this is not available, it is allowed to project above the ground, so that water can occasionally be poured down. The cast-iron cap is, last of all, inserted on the top of the tube, and serves to mark the position of the lightning conductor, a useful precaution, as conductors are often cut by workmen who have no idea of their existence. The system of tubular earth (Fig. 9) is favoured by architects, who naturally object to the deep holes necessary for the usual earth-plate being made near the foundations of a building; it also has the advantage of being considerably cheaper than other forms of equipment.

I will now put on the screen a view of a cemetery chapel at Thirsk which was struck in April, 1900. It is an unprotected building, but was quite in the shadow of the large parish church of St. Mary's which had a lightning conductor. You will see how the flash divided over the building, and, where it ran to earth, there are small upheavals of the ground. In this case the stroke divided up and earthed itself fairly quietly, but in some cases—there is the one of St. Paul's Church, Bedford, which you have seen—the great destruction which took place then was occasioned by there not being adequate earth connections to take the flash which spread all over the roof.

This slide represents a ground plan of St. Paul's Cathedral, and the lines running to the various circles are the conductors running to the numerous earths. Originally I found that the dome alone was protected and the west towers; to shield the building more completely a conductor was run all round and furnished with aigrettes as shown by the small circles, and from this the main down conductors ran to earth and others upwards to the various pinnacles and statues.

The Lightning Research Committee received reports from Germany, also from Hungary, where Dr. Moritz von Horn, of the Royal Joseph Polytechnic University, strongly recommends barbed iron wire, and states that cage lightning conductors are largely in use, both on town buildings and on farms and barns. A very interesting report has quite recently been received from Dr. Van Gulik, of Haarlem. It was made at the request of the Dutch Academy of Science. He also favours the use of iron for conductors, and suggests that the high terminal rods should be abolished. Tables are given to show the number and extent of disasters to protected and unprotected buildings, and particulars of the rebate allowed by some insurance companies where

buildings are fitted with lightning rods. The total amount of damage by lightning in Holland settled for by insurance companies is given as £84,000.

United States.

A visit paid by the author to the eastern cities and Canada was reported to the Lightning Research Committee, as follows:—

"The general opinion was that owing to the very inefficient protection which had been afforded in the past by the contractors who had installed lightning rods on many public and private buildings, it was gradually dropped out of architects' specifications, and at the present time few new buildings are protected at all! they are often struck, but as the insurance policy covers the loss, little notice is taken, although deaths occur either by direct stroke or from chimneys or masonry falling. I was informed that the present conditions were thought to be unsatisfactory, and that architects and engineers generally would like to be advised as to what protection they should adopt. That large amount of damage by fire caused by lightning does take place, is shown by the reports of the Fire Commissioners. The action of lightning when striking those high steel buildings known as sky-scrapers is peculiar, and is worth investigation, as examination does not show in what direction the current flows to earth. In many cases in New York the buildings are insulated from the ground by the fact that the foundation is blasted out of the rock which forms the island on which the city is built."

A slide is shown which illustrates a portion of the framework of a steel building. The author recommended that the roof should be in good electrical connection with the framework and the top, and that the supporting columns should be inter-connected at their base by conductors which were led to a number of permanent earths.

Subsequently I went to Canada, and on the day after my arrival in Toronto, a severe storm took place, which caused several fires from gas ignition, and a flash struck the tower of the fine modern City Hall, shattering the roofing and doing considerable damage. No lightning conductor was installed, but, as I was asked to give my opinion, I think the building has been protected in the way I recommended.

The Lightning Research Committees.—Practical Suggestions.

It is interesting to note that the English Committee are not alone in attaching great importance to this subject. Their general conclusions agree closely with the independent reports of the various continental authorities and committees, some of which have been quoted above, therefore the following suggestions are put forward as not only the results of their own investigations, but also as the practical opinions of all those who have been similarly engaged.

The suggestions appear in the report of April 10th as follows:—

"1. Two main lightning rods, one on each side, should be provided, extending from the top of each tower, spire, or high chimney stack by the most direct course.

"2. Horizontal conductors should connnect all the vertical rods (*a*) along the ridge, or any suitable position on the roof; (*b*) at or near the ground line.

"3. The upper horizontal conductor should be fitted with aigrettes or points at intervals of 20 or 30 feet.

"4. Short vertical rods should be erected along minor pinnacles and connected with the upper horizontal conductor.

"5. All roof metals, such as finials, ridging, rain-water and ventilating pipes, metal cowls, lead flashing, gutters, &c., should be connected to the horizontal conductors.

"6. All large masses of metal in the building should be connected to earth either directly or by means of the lower horizontal conductor.

"7. Where roofs are partially or wholly metal-lined they should be connected to earth by means of vertical rods at several points.

"8. Gas pipes should be kept as far away as possible from the positions occupied by lightning conductors, and as an additional protection the service mains to the gas meter should be metallically connected with house services leading from the meter."

It is hardly necessary to repeat the rules drawn up by the Committee, as they are set forth at length in their report, which gives some of the details necessary to carry out their suggestions. Some of those which were issued by the Lightning Rod Conference in 1882 are retained, and the new recommendations are principally the horizontal conductor on the ridge or summit of the roofs, and the down conductors, which are connected to this and to all metal work, and again inter-connected near the ground level. The necessity of increasing the number of the earths in proportion to the ground area of the building is also pointed out.

The insurance offices appear to disregard the question of adequate protection, and are quite content if the single conductor, which

has not prevented serious damage, for instance, to a church, is replaced, and, moreover, they take no steps to have the earth connection tested periodically. The few unconnected lightning rods erected on our national museums, picture galleries and other public buildings, contrast most unfavourably with the more scientific methods adopted on the Continent, more especially in Germany, where in some districts the local authorities have issued rules as to the erection and testing of lightning conductors, to which the various public bodies have to conform. In some cities householders are subject to penalties if the system is allowed to get out of order.

It appears anomalous that large sums of money should be spent on the protection from fire of our museums, while the question of protection from lightning is simply ignored by the department in whose care they are placed. For instance, the Victoria and Albert Museum has one conductor (it was struck in 1900, but fortunately the damage was confined to the destruction of an electric main, which served as a lightning rod, as it was laid on the wall separating the Imperial Institute from the museum). The National Gallery apparently had no conductor until the flagstaff was erected, and this is the only approach to safeguarding the building from lightning stroke, although many thousands are being spent to buy up the adjoining property. How very differently public buildings are treated abroad is shown by the view of Le Faculté, one of the public buildings in Paris, and of Notre Dame Cathedral. The British Museum authorities rely on the copper roof for protection, and the flagstaff was on my visit unprotected. The Tate Gallery appears to have inadequate lightning conductors, and the system on the Houses of Parliament, originally installed with great care, is said to require attention (the Victoria Tower was struck in 1868). The ecclesiastical authorities are, with some exceptions, indifferent, and having had some rods put up haphazard suppose that they act as a fetish or charm, or as a quack specific to cure all lightning plagues. I have visited some dozen cathedrals in the provinces, and in only one was there any attempt to protect the whole of the structure, and that was at Canterbury, where the arrangement of the conductors was faulty, in that a stroke of lightning which had travelled through perhaps half a mile of space would not, as the generality of lightning-conductor makers expect, tractably follow the copper tape, some of which had almost right-angle bends. However Canterbury stands at the head of the other cathedrals which were inspected in that the conductors had recently been overhauled and rejointed, and the earth connections tested.

At Chester the conductors were insulated and led into loose sockets close to the ground, so that any passer-by could disconnect them from earth. Time will not allow a criticism of all the buildings visited, but I must point out that the well-preserved Minster at York had only three conductors, which, according to imformation received, had not been tested or overhauled for many years. Our cathedrals and museums are of national importance, and if it is found necessary on the Continent to have a thorough system of protection and frequent inspection, surely it should be done here, as the initial expense could be spread over a number of years, and the annual upkeep would be sufficiently provided for by a one per cent. rate on the sum spent for structural repairs. The amount of damage to property by lightning stroke is enormous; unfortunately, owing to the reluctance of the insurance companies to publish details, no figures can be stated. Most people think that almost every church has a conductor, whereas not ten per cent. are so provided; in fact, although there is sometimes a recommendation from the archdeacon that the churchwarden should put up a conductor and see that it is kept in order, if the vicar wishes to safeguard his church the cost usually has to come out of his own pocket. The insurance offices do not seem to care whether a building is protected or not, as no individual office likes to insist on the erection of lightning conductors for fear of diverting business to its rivals.

DISCUSSION.

The CHAIRMAN said the protection of buildings against the effects of lightning had aroused very much interest of late, and had been debated in the Press, some of the writers having gone so far as to question whether buildings could be effectively protected against lightning. Some of the audience having seen the illustrations on the screen of damage which had been done by lightning, might also have come to the same conclusion. If they did, however, he thought they were in error, for wherever man found himself face to face with the greater forces of Nature he was doomed

to occasional failure. Man's best found ships were wrecked, his breakwaters demolished, and railway embankments washed away. He did not on that account abandon his attempts, but, on the other hand, sought improved designs, and went to work again, and generally his efforts were crowned with success. The same conclusion, he thought, might be reached with reference to lightning protection. In the early days of Snow-Harris, and others, lightning rods seemed to have been fairly effective. Cases of failure increased in number as time went by, and these might be attributable to the altered nature of buildings. These enclosed gas and water pipes, wires, and all kinds of conductors, many of them affording a direct path to earth, and the fact of putting such masses of metal and other things in the interior of buildings led to an increased number of disasters. The question had assumed such proportions and importance that in 1878 it led to the formation of the Lightning Rod Conference, which undoubtedly did good work. It crystallised the best practice of the day, called attention to the methods of dealing with conductors in the inside of buildings, and laid down most useful rules. He was afraid, however, that the electrical profession had not formed such a true idea of the character of lightning then, as they had at present. Sir Oliver Lodge was one of the first to take up the question from the point of view of the oscillatory quality of lightning, and he urged the necessity for modified methods. But he (the Chairman) was afraid that for a long time Sir Oliver was like one "preaching in the wilderness." The urgency of the matter did not at first appeal to the general body of engineers, and very few thought seriously of the question, being satisfied generally with the regulations drawn up by the Conference. He thought the attention of engineers was strongly drawn to the subject by modern developments of electrical engineering, more especially that which related to the introduction of wireless telegraphy. That itself depended upon oscillatory currents, or the use of a gentle form of lightning. The two movements were absolutely alike. The oscillations in the wireless installation were the analogue of the oscillations that took place in a lightning conductor. Considering for a moment the best practice in wireless telegraphy; the source of the energy was not connected directly to the vertical wire, which was the counterpart of the lightning rod, but very violent oscillations were established in a closed circuit, the oscillations being imparted to the vertical wire in one case by direct contact, and in the other case by induction between two neighbouring conductors. When very powerful energy was used, those oscillations extended through the line of external conductors, so that on a dark night one could see brush discharges passing off into the atmosphere in the same manner as the lightning effects which were illustrated by the author. On the other hand, the receiving apparatus was not connected direct to the vertical wire, but the connection was either through a secondary circuit, or in some cases by induction. If these facts were considered in connection with many of the cases which had just been illustrated, he thought it might be readily understood how it was that the effect of the violent oscillations in an ordinary lightning rod were not limited to that rod, but acted, either directly on all other conductors which touched that rod, or on those in sufficient proximity as to be affected inductively. The result was that in many cases at the distant end of a metallic ridging, or the guttering that surrounded a building, one would get violent discharges which, if those extremities were connected with earth, would disappear harmlessly. But if they were not so connected, damage would be done and evidences of their action would be left behind. That was a brief explanation of the basis of the work of the recently appointed Lightning Research Committee. He thought that those who were interested in the protection of buildings from lightning might assume that in this country they were not so very far behind the age; that there was no reason to give up hope of effective protection, and that the modern methods, referred to by the anthor, would afford as reasonable a protection as could really be hoped from the mighty forces of disruptive lightning. He thought the use of the lightning rod might be regarded as a species of insurance, not of the type that the author referred to, in somewhat disparaging terms, but that the amount of protection might be proportioned to the value of the buildings themselves. Buildings of no great extent or great capital value could be effectively protected in a cheap manner, but with larger and more expensive buildings and national monuments, a very large expenditure was fully justified.

Mr. J. J. RAWLINGS thought the illustration the author had shown of "Heathfield" exemplified the net-work system as far as it was possible to do so. There was almost an excessive number of points, and a large number of earths, but Mr. Hedges had not said how the earths were made, although presumably he was satisfied with them. It appeared to him that its only difference from a perfect net-work system was that it did not contain horizontal connections. He had been much struck with the important part that lead played in the system, it being stated that the current passed along the lead ridges or gutters; so that one was almost irresistibly drawn to the conclusion that lead would be the proper conductor to use. Its specific resistance was somewhat similar to iron, its lasting power was very great, and it did not possess the bad habit of marking the stone and otherwise disfiguring the building which was characteristic of iron. His firm had consistently made it a practice, especially with tall pipes, such as ventilating pipes, made of lead with soldered joints, to earth the pipes at the foot, thereby obtaining an excellent lightning conductor.

Mr. ALFRED HANDS said there were so many points in the paper to which exception could be taken that it was impossible for him to refer to them all. The author inferred that the views of experts on the question of protection from lightning up to time of the publication of the Research Committee's reports were entirely wrong; that protection under those views was a matter of impossibility, and that only now had the matter been placed in the true light. Mr. Hedges had either failed altogether to realise what the views of experts on the subject were, or else he had ignored them, because there was no resemblance whatever between what he had pointed out as being the views on lightning conductors before the Research Committee was formed and the views of experts. The author had taken the popular idea of people who had never studied the subject, which was absolutely different to the opinion of experts. With regard to the question of damage by lightning, he reminded the audience that an enormous number of cloud-to-earth lightning discharges took place in the country every year; and since very lofty buildings were admittedly more liable to be struck by lightning than low ones—and as practically all the very lofty buildings in the country were fitted with lightning conductors, remarkably few of which were protected in accordance with the author's views—was not it reasonable to suppose that an alarming number of failures of lightning conductors would take place if Mr. Hedges was right and the experts were wrong? From a very close investigation of the subject, extending over the last 17 years, he believed that between 300 and 400 buildings were struck and damaged by lightning every year in the country, out of which less than a dozen possessed lightning conductors. The buildings must have been in existence for terms varying from 20 to 60 years, and the rods had been put up by ironmongers, plumbers, builders, and others, whose callings did not imply that they were experts; and they had never had the slightest attention in the course of that time. Was a lightning conductor to be regarded as the one thing in the world which should remain efficient for half a century without attention or repair, and irrespective of whether it was put up properly in the first instance? The author had laid stress on the fact that the Research Committee received accounts of 125 cases, out of which 40 had lightning conductors; but so far as he could see only 34 were given in the published list, and of that number seven had no lightning conductors at all, although the committee said they did not consider it necessary to give details of the unprotected buildings that were damaged, and confined themselves to giving particulars of the protected buildings. He did not know whether that was a mistake or not; it seemed to him it was given with the idea of making the impression that everybody was wrong on the subject and that lightning conductors always failed. In addition, one case never occurred at all, and if it did take place it happened many years ago, long before the committee was formed. He would like to know whether the list of 40 included the case of damage to the Houses of Parliament, which the author reported to the committee, and for which there was no foundation whatever, and whether there were similar cases among the number. He further contended that the author's remarks with regard to lightning conductors attracting lightning were incorrect, Snow-Harris combating the idea very strongly. The question of side-flash was also not a new one, Snow-Harris referred to the subject half a century ago, although his ideas were not quite correct, present day experts knowing much more about the matter. The cage system was not new, experts having always regarded it as the best system of protection available, provided it could be applied. It was the best system, for the reason that when it was employed in its entirety there was no necessity to examine the inside of the buildings; but it was not practicable. In the first place the cost was prohibitive, and secondly a building could not be protected in the manner unless it was detached. One thing experts knew was that the bastard cage system which the author had recommended was not equally effective; in fact Mr. Hedges had condemned it himself by saying that to protect a building perfectly it was necessary to have a complete bird-cage system, while he recommended what he (Mr. Hands) would call a bastard one. The system was adopted in the Hotel de Ville, at Brussels, but was not composed, as the author stated, of conductors formed of copper wires, but of iron wires,—the very system that was being suggested now, and which, although, the author said was efficacious, failed, the building having been set on fire by lightning.

Mr. HEDGES, in reply to Mr. Rawlings, said the point he wished to emphasise in connection with "Heathfield" was that the conductors were not inter-linked, otherwise the damage would probably not have occurred. He could confirm Mr. Rawlings's remarks that lead was an excellent material to use, by stating that in the Bedford church which was struck by lightning some of the pipes which took the discharge were lead pipes; they were not melted, but only bulged out so that the pipes became oval in shape. He did not think, however, that lead could be generally used owing to its expense. He quite agreed that the lead pipes should be earthed. With regard to Mr. Hands's remarks, he did not wish to blame everybody in the sweeping way that gentleman imagined. The committee did not select the cases of protected buildings which were given; the observers, who were perfeetly neutral, self-appointed gentlemen, among whom was Mr. Hands, performed that function, and if Mr. Hands thought that work was being done in the wrong direction during the four years the Research Committee was in operation, it was his duty to have written to the secretary and complained of the fact. The views he had stated were not his own, but those

of the Research Committee. Mr. Hands had referred to an inaccuracy in the number of cases given. To the best of his belief forty cases were ordered to be inserted in the report; but if any errors had crept into the published report he was only too pleased to have them pointed out, and would make the necessary corrections in the next edition. Even supposing there were only 35 or 37 cases instead of 40, he contended that was a very large proportion of buildings fitted with lightning conductors to be struck by lightning out of the total number which the committee examined. The case in which damage was reported to have occurred at the Houses of Parliament through a stroke of lightning crept in in a very curious manner. In passing down Palace-yard, he noticed that a considerable crowd had assembled, and was told that the Victoria Tower had been struck by lightning. It was very difficult to verify such a statement because the authorities would not allow anybody to inspect the building, but he was told that pieces of flagstones were lying about in the road just at the time. The evening papers all contained statements to the effect that the building had been struck, and as the list was being made up at the time, it was included; but the list was a private document, and was never intended to be circulated, except to those immediately connected with the Research Committee. The entry was immediately erased when it was discovered that the report was a mistake; and he hardly thought it was a nice suggestion to make that the committee had deliberately published false information. It was rather late, now that all the work had been done, for Mr. Hands to condemn it; the work had been very largely advertised, and he was sorry Mr. Hands did not come forward earlier and give the results of his experience. Personally, he had been led to investigate the subject because he could not find anything to guide him, but he did not wish to condemn what other gentlemen had done. He had never had occasion to see any of Mr. Hands's work, but he had carried out a good deal of work in connection with electric-lighting stations, and on examining it he found it was so terribly bad that he determined to start again, and put in appliances which he thought would have a much more lasting effect. He quite understood that firms such as Mr. Hands represented could do good work, and he should be very sorry indeed if it was supposed that he in any way condemned the work done by such firms. Looking at the examples of work which he had shown there were two reasons for the failure, either that the work was not good, otherwise they would not have been struck, or else that the system which had been adopted was not sufficient. He thought that instead of cold water being poured on the work of the gentlemen who had investigated the subject, they ought to be encouraged in their endeavours. It was of primary importance that architects should have it brought to their earnest consideration that if a building cost a lot of money to erect it was worth while spending a good sum of money to protect it. As the Chairman had remarked, it was simply a question of insurance.

Mr. HANDS, in explanation, said that although the document which contained statements connected with the Houses of Parliament was originally marked "private and confidential," it was afterwards exhibited for a period of nearly six months at the Earl's Court Exhibition, with the words "private and confidential" erased, and with the case of the Houses of Parliament not deleted. He therefore thought he was justified in mentioning the matter.

The CHAIRMAN thought he could explain one small discrepancy which had been referred to by Mr. Hands. There were forty cases, but he had personally struck out three of them, because they did not refer to the protection of buildings by lightning rods, but to the protection of telegraph instruments by lightning protectors used for that purpose. He therefore struck them out because he thought they bore no direct relation to the report of the Lightning Research Committee. In conclusion, it was his pleasant duty to propose a hearty vote of thanks to Mr. Hedges for his able paper.

The resolution having been carried by acclamation, the meeting terminated.

IRRIGATION IN CANADA.

From the eastern foot-hills of the Rocky Mountains, at a point 15 miles south of the boundary between Canada and the United States, a ridge or height of land starts out in an easterly direction, crossing over into Canada, and running nearly parallel with the international boundary, about 40 miles north of it, for a distance of something over 400 miles, thence turning in a south-easterly direction through North Dakota. A similar ridge runs out from the mountains at a point about 300 miles north of the United States boundary, in a north-easterly direction, traversing the great peninsula towards the Hudson Bay. Between these two ridges lies the basin of the Saskatchewan, subdivided into the main valleys of the North and South rivers, with the affluents of these. This is the prairie country which in the early part of the last century was known as Rupert's Land, latterly attached to the Canadian Federation as the North-West Territories, and on the 1st of July to become organised provinces of the Dominion. If the measure now before Parliament is passed in its present form, the Province of Alberta will comprise the territory lying west from the fourth grand meridian—line 110 of west longitude—to the easterly boundary of British Columbia; and the territory extending easterly from that meridian to the

westerly boundary of Manitoba will constitute the Province of Saskatchewan.

The area of land embraced in the basin of the Saskatchewans is approximately 150,000,000 acres. Of this perhaps one-third may be described as sand or gravel, with a light covering of soil, not capable of producing any other crop than the wild grass which covers the entire country in the early part of the summer. But there are 100,000,000 acres of rolling prairie land having a fertile surface soil of loam resting upon a cultivable clay, suitable in chemicel constituents for the production of wheat and other cereals. The experience of the last twenty-five years has shown that good crops can be raised in rainy seasons, but there are periods of drought in which agricultural operations are unprofitable. In regard to rainfall there is an important distinction between the north and south valleys. Towards the north, the mountain ranges of British Columbia are traversed by deep valleys, notably those of the Peace and Pine rivers, through which the moisture-laden breezes from the Pacific Ocean pour into the prairie country, ensuring equable and adequate precipitation throughout the northern districts. Very different conditions prevail in the valley of the South Saskatchewan. This is shut off from the ocean winds by a huge rampart of mountains intersected only by narrow ravines or "canyons;" and west of the mountains there is the broad valley of the Fraser River, running north and south, which intercepts and precipitates a large share of the moisture coming inland on the sea breezes.

In the South Saskatchewan valley and a south-easterly section of the north valley, with the 40 mile strip fronting on the United States and tributary to the Missouri basin, there is an area of something over 64,000,000 acres, designated in the Canadian Government reports as the "semi-arid region." The easterly limit of this is shown on the official maps at 106 longitude from the United States boundary to a point a few miles south of latitude 52. The general level of this district rises from 2,000 feet above sea in the easterly section to 3,500 feet in the west. Records kept at observing stations for 18 years show that the annual precipitation of rain and snow varies from 6 inches to 15 inches, the minimum report being from Chaplin, near the easterly limit of this district, at a point 2,202 feet above sea, where the register gives 50 inches as the total precipitation for 9 years, equivalent to an annual average of 5½ inches, or a monthly average of less than ½ inch. Going west towards the head of the valley the rainfall shows a considerable increase, and approaching the mountains the general average exceeds 15 inches per annum.

The most important point established by the Government records is the regular alternation or recurrence of wet and dry periods, each extending over a series of years. As a rule, this alternation comes every fifth year; that is, after four consecutive rainy summers there will follow four dry years. In the rainy summers the prairie soil is capable of producing marvellous crops, but in the dry years all vegetation fails. In the last thirty years farming operations have been attempted in many parts of the district, but without permanent success, except in valley bottoms, or in the vicinity of lakes or ponds supplied from the melting snow. It is now an acknowledged fact that good crops cannot be ensured in the seasons of drought, unless there is artificial irrigation.

Of late years there has been a large influx of Mormons into the upper part of the South Saskatchewan valley. Many of these people had had experience in the cultivation of irrigated lands in Utah, and they soon perceived that the same methods were necessary on the Canadian prairie. They built dams and constructed watercourses, with very little regard for engineering technicalities, but their efforts have been successful in every sense. Large tracts of land which were formerly available only as pasture for a few herds of cattle in the early spring and late in the autumn are now producing heavy crops of wheat and other cereals. The example set by these Mormon immigrants was quickly followed in other sections of the valley, and large areas were soon brought under cultivation. Associations were organised for the purpose of constructing irrigation works on a large scale; and at the present time there are upwards of 500 miles of canals and ditches capable of supplying water throughout the season for an average of 1,000 acres per mile. This does not include the extensive work now undertaken by the Canadian Pacific Railway in the vicinity of Calgary which will bring under cultivation 1,000,000 acres of land included in the original grant from the Government.

The total area in this region of land for which water supply is available in sufficient quantity to provide for irrigation throughout the crop season is officially estimated at 15 per cent. of the whole. This gives something less than 10,000,000 acres of irrigable lands, mainly in the western or upper end of the south branch. The works now under construction in this section will unquestionably cut off a large share of the water supply of the lower part of the valley, and many millions of acres will remain permanently unwatered, except in seasons of abnormal rainfall. These non-irrigable lands, in the words of the official report of 1903, "for all time to come must be devoted to grazing." For this purpose the semi-arid lands are not surpassed by any part of the American continent; the wild grasses mature rapidly in the early part of the summer, and a little later the whole region is one vast hay-field.

In this great treeless plain evaporation is very rapid, especially under the influence of the dry winds coming from the alkali deserts of the far south. The high altitude and the prolonged hours of sunlight in the summer months afford every facility for free radiation. A sudden lowering of temperature comes immediately after sunset, and a

frosty night may follow after a day of almost tropical heat. These summer night frosts are said to be less prevalent in the irrigated districts.

An international question of some importance has arisen in connection with the irrigation schemes in the 40-mile strip bordering upon the United States, and within the southern watershed. The principal watercourse of that district is the Milk River, which has its origin in a small lake south of the boundary, thence crossing over into Canada, and flowing easterly a hundred miles before finally turning southward. On the Canadian side there are large areas of prairie land, which can be fertilised only by the waters of this river, and on the United States side there is a similar stretch of country, which has a pressing claim upon the same source of supply. The Washington Government is undertaking very extensive work for the purpose of irrigating its lands in that vicinity, and has taken steps to provide the necessary head of water by building a dam across the outlet of the upper lake. This practically shuts off the supply from a hundred miles of Canadian territory. A Joint Commission has lately been appointed by the two Governments to investigate and come to some understanding respecting this and several other questions of similar nature which have arisen from the alleged diversion of international waters.—*The Engineer.*

LABOUR STATISTICS.

The tenth abstract of Labour Statistics of the United Kingdom just issued (Cd. 2491), presents in convenient form a mass of information of interest to the sociologist. Turning first to trade unions the returns show that between 1892 and 1903 they increased in number from 1,188 to 1,294 in 1896, when the total membership was 1,502,714. After 1896 there was continuous decrease until 1903 when the number stood at 1,166, but the total membership had increased to 1,902,308. Taking 100 of the principal trade unions, the membership increased from 902,763 in 1892 to 1,133,640 in 1903, the income from £1,462,386 to £2,073,612, the expenditure from £1,433,111 to £1,895,015, and the funds from £1,573,944 to £4,550,775. the amount per member at the end of 1903, £4 0s. 3½d., being the highest on record, and comparing with £1 14s. 10½d. in 1892. All the principal trade unions show a large increase of membership with the exception of the clothing unions. Between 1892 and 1903 the building unions increased their membership from 132,934 to 204,060, the mining and quarrying from 203,800 to 266,968, the metal, engineering, and shipbuilding from 177,692 to 244,691, the textile from 107,164 to 116,654, but the clothing fell from 64,512 to 45,353. So with income. All show large increases with the exception of the textile and clothing, the one falling from £192,881 to £186,545, the other from £68,587 to £60,791, but whilst the expenditure of the textile unions fell from £225,203 in 1892 to £205,607, the clothing unions show a slight increase from £61,748 to £62,031.

The expenditure on chief benefits necessarily varies very much. Taking the 100 unions, the highest percentage spent in dispute benefit was in 1897, when 34·7 per cent., or £659,079, was spent in this way. The highest percentage under this head is found in the mining and quarrying section, where in 1893 no less than 66·4 per cent. of the expenditure was for dispute benefit, and the average percentage of the 12 years was 32·9. The dispute benefit paid by the printing and allied trades is the lowest, being little over 5 per cent., and, taking the last 5 years, under 4 per cent.; but, whilst the mining and quarrying unions pay nothing for superannuation benefit, and in 1903 their "working and other expenses" reached 27·8 per cent., the unions of the printing and allied trades spent 21·2 per cent. in superannuation benefit, and their percentage of working expenses was only 16·8. The financial position of the principal unions was never so good as at the present time. Without exception their funds at the end of 1903 were greatly in excess of what they were in 1892, having increased in the aggregate from £1,573,944 to £4,550,775. The building unions had increased from £169,956 to £475,290, the mining and quarrying from £305,383 to £1,020,002, the metal, engineering, and shipbuilding from £578,317 to £1,562,942, the textile from £174,997 to £664,920, the printing and allied trades from £77,923 to £170,994. Even the clothing unions improved their position from £54,717 to £98,016.

The registered friendly societies also show continuous and great expansion. Taking all classes making returns, the ordinary friendly societies, the collecting friendly societies, and the special classes of friendly societies, the membership increased from 10,934,144 in 1897, with funds amounting to £35,736,250, to 13,344,494 in 1902, with funds amounting to £44,848,575. The Manchester Unity, Oddfellows, who, in 1886, had a membership of 550,729, and an income of £969,754, had in 1903 increased their membership to 755,982, and their income to £1,492,352; and the Ancient Order of Foresters who in 1886 numbered 594,921, with an income of £892,613, had in 1903 increased their membership to 664,519, and their income to £1,357,777. In 1903, the total accumulated funds (exclusive of foreign branches and of "female" and "juvenile" branches) of the Manchester Unity of Oddfellows stood at £10,277,366, and of the Ancient Order of Foresters at £6,748,682, and the total benefits of all kinds paid on account of male adults by the one society was £925,712, and by the other, £838,213. On the other hand, building societies have decreased in number. Taking the years following the passing of the Building Societies Act, 1894: in 1895, the number of societies making returns, in England and Wales, was 2,181, with total liabilities of £40,597,050. In 1903, the number had dwindled to 1,861, but the liabilities had

increased to £48,243,848. The loan societies, that is to say the societies registered under the Loan Societies Act, 1840, steadily dwindle. In 1885 they numbered 408, in 1902 only 254. In 1885 the membership was 41,065, in 1902 it had fallen to 32,684. The number of borrowers to whom loans were granted in 1885 was 82,655, in 1902 to 54,322. The amount in borrowers' hands at the end of 1885 was £299,481, at the end of 1902 it had fallen to £202,859, whilst the amount due to depositors and shareholders had decreased from £321,157 to £242,405. Workmen's co-operative societies show steady increase. In 1888 there were 1,447 in existence, in 1903 2,291. Of these, 1,263 made returns in 1888, and 2,027 in 1903. The number of members in the societies making returns increased from 891,088 in 1888 to 2,085,731 in 1903, the percentage to the population of the United Kingdom from 2·4 to 4·9, the share capital from £9,757,269 to £26,596,373, the loan capital from £2,129,059 to £7,989,443, the amount of sales from £33,632,224 to £87,975,651. The number of accounts open in the Post Office Savings Banks in the United Kingdom shows large and continuous increase from 4,220,927 in 1888 to 9,403,852 in 1903; those in the Trustees Savings Banks having increased from 1,579,546 to 1,689,617 only. But the amounts received from depositors in the United Kingdom, whilst showing steady increase from 1888 to 1902, as from £20,385,064 to £45,607,672 in 1902, showed some decrease, falling in England and Wales from £41,117,126 to £39,854,156, and in Scotland from £1,176,469 to £1,699,716. It is worthy of note that in Ireland there has been uninterrupted increase from £1,191,178 in 1888 to £2,762,222 in 1903.

The percentage proportion of working population involved in disputes shows a gratifying decrease, taking the decade 1893-03. In the earlier year the percentage was 7·5, in 1903 only 1·2. If coal mining disputes were excluded the percentage would be very small. In 1893, the coal mining percentage was 74·7; in 1894, 31·2; in 1895, 25·2; in 1902, 25·5. In no other trade throughout the period was the percentage higher than 8·6, which it reached in the clothing trade in 1895, the metal, engineering, and shipbuilding coming next with 7·8 in 1897. The aggregate duration of disputes in working days, which, in 1897, was 10,345,523, and in 1898, 15,289,478, fell last year to 1,416,265. Taking the causes of disputes, by far the largest number is due to demands for increase of wages, next against decrease, wages disputes accounting in 1893 for as much as 90·8 per cent. of the whole, and 58·9 in 1904. Other causes of dispute are concerned with hours of labour, employment of particular classes of persons, working arrangements, and trade unionism.

BELGIAN CHICORY.

During the months of January, February, and March attention is attracted to the immense quantity of a special vegetable sold by marketmen, greengrocers, and hucksters, and eaten by all classes throughout Belgium, prepared in various appetising ways, and frequently eaten as a salad, either raw or cooked. This is the white chicory, the cultivation of which is a speciality of Brussels and its suburbs. There are two species of chicory grown in Belgium. The wild chicory, cultivated in the neighbourhood of Roulers, Thourout, and one or two other localities, in close proximity to the chicory manufactories, where the roots of the plants are parched, ground, and sold loose or in half-pound packages, to be used in connection with coffee, especially by the working classes. The white chicory was originally brought to Belgium from India, and the principal centre of cultivation, according to the American Consul at Brussels, is in the immediate neighbourhood of Brussels, especially in Schaerbeek, Evere, and Woluwe. The root of this plant is of inferior quality and is consequently used as cattle food. The growing of this essentially winter vegetable requires great care, trouble, and hard work, beginning early in April, when the seed is sown. As soon as the plants are an inch and a-half high, they are carefully thinned out by hand, leaving the most vigorous undisturbed, a given distance apart. In September and October, when the plants are in full maturity and the leaves are very long, they are taken out of the ground, and the leaves carefully cut off about two inches from the ground. Trenches are prepared, and the plants are disposed of in them in three layers, each layer being covered by ten inches of earth and from twelve to fourteen inches of horse manure. This manure produces artificial heat, which causes the chicory to sprout, and the earth being compactly pressed upon the plants, the leaves adhere closely together, and as no sunlight penetrates the covering, the plants are bleached white, and present a most attractive and appetising appearance when removed for consumption. This is done according to the demands of the market. The vegetable is available all the year round, but the most active demand is in the months of January, February, and March, during the scarcity of other garden vegetables. The above-described method of bleaching chicory has existed since the commencement of the cultivation of this popular vegetable, but much complaint is heard concerning it principally on account of the germs contained in the horse manure, which is likely to render the vegetable unwholesome and unfit for consumption, and also on account of the danger of a sudden frost, which, by lowering the temperature of the manure covering, checks the growth of the plants, and correspondingly affects the selling price. To combat these inconveniences, the cultivators of chicory at Schærbeek, one of the most important suburbs of Brussels, have for some time been experimenting by heating the layers of plants by the system of thermo-syphons. The system has the advantage of giving a regular, constant heat, and greatly reduces the manual labour connected with the cultivation. Although an immense quantity of

chicory is consumed in Belgium, the yield is sufficient to supply Paris with large quantities, where it is largely used in the hospitals of that city. The average wholesale selling price in Belgium is about two pence per pound, and in Paris about double that price. To perform all the different operations connected with chicory growing demands hard work and constant attention. The most dangerous part of the work is the loading and transportation of manure which has to be done before eight o'clock in the morning. The great difference in the temperature of the cavalry and other stables, where the horse manure is obtained, and the temperature of the outside cold and chilly morning air, frequently results fatally to the men employed in this work.

FRUITS AND CEREALS OF WESTERN AUSTRALIA.

The Agent-General for Western Australia opened on May 1st, at his offices, 15, Victoria-street, Westminster, a small exhibition of apples and cereals received from the State.

It is officially stated that the object of the Agent-General in making this display is:—

1. To illustrate the fact that Western Australia has other claims upon public attention than her gold production.

2. To demonstrate the possibility of the creation of an important export trade in agricultural products with the Mother Country, in proof of which he is pleased to say that a cargo of 5,000 quarters of wheat shipped per ss. *Chili*, by the West Australian Producers Co-operative Union, Limited, has just been sold by Messrs. Berry, Barclay and Co. at 31s. per 480 lbs. (this being the first large consignment of Western Australian wheat placed upon the English market), and that a second consignment per ss. *Suffolk* is being sold at 33s. 6d. per 496 lbs. *ex store*, and

3. To give prominence to the policy of his Government in encouraging the emigration to Western Australia of suitable settlers.

Three kinds of apples, viz., Cleopatra's, or New York pippins, Dunn's seedlings, or Munro's favorites, and Jonathans were received from Katanning (on Great Southern Railway, about 225 miles from Perth), and the Darling Range (about 10 miles from Perth.)

Reports from fruit brokers have been received—Messrs. Keeling and Hunt, of Monument-buildings, E.C., say:—"Condition on arrival—almost pefect; quality all round—very good; size—generally too large for market purposes." Messrs. Yuill and Co., Limited, of 120, Fenchurch-street, E.C., report that:—"The fruit was in splendid condition and of exceptionally good quality."

The wheat, &c., come from the Government experimental farms, Hamel (on the South Western Railway, 71 miles from Perth); Narrogin (on Great Southern Railway, 162 miles from Perth); Chapman (on the Northampton Railway, 337 miles from Perth).

Hamel sends 51 varieties of wheat, 10 oats, 3 barley, 1 rye, 8 maize, 1 peas, and 1 linseed. Narrogin sends 9 varieties of wheat (including sample which won the Kangaroo Cup), and 1 malting barley. Chapman sends 10 varieties of wheat in sheaves and grain, 4 oats in sheaves.

BOLIVIAN FOREST PRODUCTS.

The immense Bolivian forests on the eastern portion of the Republic abound with excellent timber, but no effort has been made so far to develop this industry which is expected to yield handsome profits to promoters. Ebony, mahogany, cedar, rosewood, satinwood, walnut, hemlock, beech-wood, holly, boxwood, "colo," are extremely hard wood not affected by moisture of any kind, "jacarandi," a remarkable wood of variegated colours, and the quebracho, a species of ironwood used for sleepers on account of its extraordinary resistance, are among the few known species of forest products. In Bolivia, according to a recent report of the Bureau of American Republics, there is to be found a great variety of dyewoods and precious medicinal plants, from which may be distilled fine essential oils, while the mountain slopes, hills, and valleys abound in valuable construction and cabinet woods. The celebrated ironwood tree attains a height of over 50 feet, and a circumference of nearly three feet. The specific gravity of this exceedingly compact and durable wood is 1·250, and the contents of tannin 26 per cent. This wood is used extensively for railroad ties, posts, &c., and is employed in considerable quantities in tanneries. Another valuable product of the Bolivian forests is the tree known as "Corupan," which grows to a height of about 60 ft., and attains a diameter of over 3 ft. The wood of this tree does not decay when immersed in water, which quality renders it exceedingly valuable for use in the construction of ships, bridges, and hydraulic work. It makes a very durable railroad tie, and the bark, which is very thick, contains about 25 per cent. of tannin. The tree secretes an abundance of gum arabic, and is one of the most valuable and highly prized productions of the Bolivian forests. "Lapach" is a tree noted for its great beauty and usefulness. It grows to a height of about 60 ft., and has a circumference of trunk of about 3 ft. When sawn into lumber or beams it is greatly esteemed for building purposes, and is especially suitable for use in the building of hydraulic works and for railroad ties. There are four varieties—the grey, the yellow, the red, and the black—all of which may be distinguished while in bloom by the colour of their flowers. The bark is rich in tannin, and the wood is utilised in the manufacture of dyes. "Mumday" is a greatly prized Bolivian tree, and is suitable for railroad ties, telegraph poles, and general building purposes. There are three varieties—white, yellow, and black. It is also a dyewood.

GENERAL NOTES.

CANALS AND WATERWAYS.—The advantages offered to many classes of goods by water transportation is illustrated anew in Mr. Consul-General Hearn's report on the trade and commerce of Havre and district (Annual Series 3368) just issued. Rouen is one of the points of access to the almost perfect system of canals and rivers which France possesses, giving uniform depths for navigation over great distances. As an example, the shipment of feldspar from Norway to the central part of France may be taken. Feldspar of the same quality as that brought from Norway is found in great quantities about 100 miles from a large button factory situated on the Canal de Briare, in the Department of the Loire. There being, however, no canals or waterways connecting the district where the crude article is found with that in which the button factory is situated, it was found more advantageous to bring the Norwegian article to Rouen by sea, then transfer it directly into lighters, and forward it by waterways into the central part of France to the button factory. During 1903, 1,252,632 tons of merchandise were shipped from Rouen by canal into the various districts in France, part going beyond the frontiers into other countries, over 50 per cent. of the shipments being foreign importation *viâ* Rouen, and 336,184 tons of merchandise were brought to Rouen by canal during the same period. The statistics for 1904 are not yet completed, but the Consul-General is informed on good authority that the canal and river shipments to and from Rouen exceed those of 1903.

INTERNATIONAL EXHIBITION OF PEDAGOGY AT BARCELONA.—An International Exhibition of Pedagogy, under the patronage of the King of Spain and of Queen Maria Christina, will be held in Barcelona from May to October, 1905. Particulars as to the scope of the exhibition and the conditions attaching to exhibits are given in the official programme, a limited number of copies of which can be obtained on application to the Director of Special Inquiries and Reports, Board of Education Library, St. Stephen's House, Cannon Row, Whitehall, London, S.W.

MEETINGS FOR THE ENSUING WEEK

MONDAY, MAY 29...National Indian Association, Jehanghir Hall, Imperial Institute, S.W., 4½ p.m. Annual Meeting.

Surveyors, 12, Great George-street, S.W., 3 p.m. Annual Meeting.

TUESDAY, MAY 30...Optical Convention, Northampton Institute, Clerkenwell, E.C., 8 p.m. Opening Ceremony and Conversazione.

Royal Institution, Albemarle-street, W., 5 p.m. Rev. Henry G. Woods, "Velasquez." (Lecture II.)

Horticultural, 1 p.m. Flower Show in the Inner Temple-gardens.

WEDNESDAY, MAY 31...Optical Convention, Northampton Institute, Clerkenwell, E.C., 10 a.m. Reading of Papers and Discussion.

British Astronomical, Sion College, Victoria-embankment, E.C., 5 p.m.

THURSDAY, JUNE 1...Optical Convention, Northampton Institute, Clerkenwell, E.C., 10 a.m. Reading of Papers and Discussion.

Royal Institution, Albemarle-street, W., 5 p.m. Prof. J. A. Fleming, "Electromagnetic Waves." (Lecture II.)

Chemical, Burlington-house, W., 8 p.m. 1. Messrs. F. B. Power and M. Barrowcliff, (a) "The Constituents of the Seeds of Hydnocarpus Wightiana and of Hydnocarpus Anthelmintica. Isolation of a Homologue of Chaulmoogric Acid;" (b) "The Constituents of the Seeds of Gynocardia Odorata." 2. Mr. A. E. H Tutton, 'The Relation of Ammonium to the Alkali Metals. A Study of Ammonium Magnesium and Ammonium Zinc Sulphates and Selenates." 3. Messrs. M. C. Forster and H. E. Fierz, "Camphorylazoimide." 4. Messrs. G. T. Morgan and W. O. Wootton, "Influence of Substitution on the Formation of Diazioamines and Aminoazo-compounds. Part III. Azo-derivatives of the Symmetrically Di-substituted Primary Meta-diamines." 5. Mr. G. T. Morgan and Miss F. M. G. Micklethwait, "Diazo-derivatives of Mono-acylated Aromatic Para-diamines." 6. Messrs. H. E. Armstrong and W. Robertson, "The significance of Optical Properties as Connoting Structure; Camphorquinone—hydrazones—oximes; a contribution to the Chemistry of Nitrogen." 7. Mr. W. Robertson, "Solubility as a measure of the change undergone by Isodynamic Hydrazones. (1) Camphorquinonephenylhydrazone. (2) Acetaldehydephenylhydrazone." 8 Mr. T. M. Lowry, "The Design of Gas-regulators for Thermostats." 9. Messrs. H. A. D. Jowett and C. E. Potter, "The Constitution of Barbaloin." Part I. 10. Messrs. G. T. Morgan and A. Clayton, "Influence of Substitution on the Formation of Diazoamines and Aminoazo Compounds. Part IV. 5-bromo-*as*(4)-dimethyl-2:4-diamino-toluene." 11. Messrs. F. D. Chattaway and W. H. Lewis, "The Action of Hypobromous Acid on Piperazine." 12. Messrs. W. A. Tilden and J. A. Stokes, "The Action of Magnesium Methyl Iodide on Pinene Nitroso-chloride." 13. Messrs. A. McKenzie and H. B. Thomson, "Racemisation Phenomena during the Hydrolysis of Optically Active Menthyl and Bromyl Esters by Alkali."

FRIDAY, JUNE 2...Optical Convention, Northampton Institute, Clerkenwell, E.C., 10 a.m. Reading of papers and discussion.

Royal Institution, Albemarle-street, W., 9 p.m. Mr. George Hentschel, "Personal Recollections of Johannes Brahms."

Art Workers' Guild, Clifford's-inn Hall, Fleet-street, E.C., 8 p.m. Lecture on "Marble Carving," with demonstration.

Geologists' Association, University College, W.C., 8 p.m.

Philological, University College, W.C., 8 p.m.

Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m.

SATURDAY, JUNE 3...Optical Convention, Northampton Institute, Clerkenwell, E.C., 10 a.m. Conclusion of Meeting.

Royal Institution, Albemarle-street, W., 3 p.m. Mr. Savage Landor, "Exploration in the Philipines." (Lecture II.)

Journal of the Society of Arts.

No. 2,741. VOL. LIII.

FRIDAY, JUNE 2, 1905.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

NOTICES.

CONVERSAZIONE.

The Society's Conversazione will be held, by arrangement with the Council of the Royal Botanic Society, in the Gardens of that Society, Inner-circle, Regent's-park, on Tuesday evening, the 4th of July, from 9 to 12 p.m.

The central portion of the Gardens only will be used. The Gardens will be illuminated with coloured lamps, and also by the Kitson Incandescent Oil Light. The Conservatory and the Club-house will be open.

The Reception, by Sir William Abney, K.C.B., F.R.S., Chairman, and the other Members of the Council, will be held at the entrance to the Conservatory, near the Broad Walk, from 9 to 10 o'clock.

The Tropical House, containing the Giant Water Lily (Victoria Regia), Banana, and other interesting tropical plants, will be open to visitors.

An Exhibition of Economic Plants, &c., grown in the Gardens of the Royal Botanic Society, together with specimens from that Society's Museum, will be on view in the Corridor.

A Selection of Music will be peformed by the String Band of the Royal Artillery in the Conservatory, and by the Band of H.M. Grenadier Guards in the Gardens, commencing at 9 o'clock.

Two performances of Selections from Pastoral Plays will be given in the Gardens by Mr. Patrick Kirwin's Idyllic Players at 9.30 and 10.30 p.m.

A concert and entertainment, including the screen scene from "The School for Scandal," will be given in the Club-house, from 10 to 10.45 p.m.

Light refreshments (tea, coffee, ices, claret-cup, &c.) will be provided.

Each member is entitled to a card for himself (which will not be transferable) and a card for a lady. In addition to this, a limited number of tickets will be sold to members of the Society, or to persons introduced by a member, at the price of 5s. each, if purchased before the day of the *Conversazione.* On that date the price will be raised to 7s. 6d.

Members can purchase these additional tickets by personal application, or by letter addressed to the Secretary at the offices of the Society, John-street, Adelphi, W.C. In all cases of application by letter a remittance must be enclosed. Each ticket will admit one person, either lady or gentleman, and must be signed by the member applying for it.

Tickets will only be supplied to non-members of the Society on presentation of a letter of introduction from a member.

COVERS FOR JOURNAL.

For the convenience of members wishing to bind their volumes of the *Journal,* cloth covers will be supplied, post free, for 1s. 6d. each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

The MAHARAJA GAEKWAR, before introducing Mr. Tozer, thanked the Council of the Society for having invited him to preside over the meeting The author of the paper required no introduction. He had on a previous occasion read a paper befor the Society, and was a well-known authority on the subject.

The paper read was—

THE MANUFACTURES OF GREATER BRITAIN.—III. INDIA.

By Henry J. Tozer, M.A.

In this series of papers, dealing with the manufactures of Greater Britain, it is my privilege to set forth the position of India. The proclamation of Queen Victoria as Empress of India in 1877 was a striking recognition of the fact that India is an Empire within an Empire—that India, more than any other portion of the British Empire, gives the Empire its Imperial character. In virtue of her ancient civilisation, her vast population, her enormous productive power, and her generous contributions in men and money to the defence of the Imperial fabric, India may justly claim the first consideration after England herself.

Great diversity of climate and large tracts of fertile soil enable India to produce abundant and valuable crops, and to carry on an active internal and external trade. According to a Parliamentary paper (342/04), the sea-borne commerce of India in 1902-03 was greater than that of Canada and Australia combined, as the following figures show (in millions of £s):—

	Imports.	Exports.	Total.
India......	74·1	92·7	166·8
Canada....	27·4	33·2	60·6
Australia ..	37·8	48·2	86·0

In 1903-4, the trade of India reached £200,000,000, and even this high figure has certainly been much exceeded in 1904-5. In Coronation year an inscription on a cereal arch erected in Whitehall claimed that Canada was the granary of the Empire. But that position is really held by India, which is too modest or too unenterprising to advertise. During the last three years India has supplied England with 51,384,000 cwt. of wheat, while Canada has furnished only 26,525,000 cwt. of wheat and 6,627,000 cwt. of flour. Again, if we regard the three great countries as markets for British produce, we find that in 1904 the purchases of Canada and Australia together amounted to only £27,868,000, while those of India were £40,617,000, or nearly 50 per cent. greater. In 1904 also India bought no less than one-third of Lancashire's exports of cloth. One great reason why so many British goods find their way to India is to be discovered in the second fiscal Blue-book of the Board of Trade (2337/04), which shows that the average duties levied on imported British manufactures are 17 per cent. in Canada, 9¼ in New Zealand, 6½ in Australia, 6 in South Africa, and only 2¾ per cent. in India. The chief British import into India, viz., cotton cloth, pays only 3½ per cent., and a countervailing excise duty is imposed, but in Canada similar goods pay 17 to 23 per cent. and no excise duty is levied. The one duty is for revenue, the other for protection, largely against British manufactures. I can only advert to the extensive interests that England has in India owing to her investments of hundreds of millions of capital, and to the large numbers of Englishmen employed in the army and civil service and in mercantile pursuits. And last, but not least, it must be remembered that India contributes 150,000 men and £20,000,000 in money to Imperial defence—an item that cannot be disregarded, as it is ultimately a charge on her industries.

India resembles the self-governing colonies in being mainly agricultural, but she differs from them in having a large and closely-packed native population. While India contains 300,000,000 people, or about three-fourths of the whole population of the British Empire, Canada has only 5,371,000, and Australia 3,776,000, the respective densities per square mile being 167, 1½, and 1¼. The character of the different populations, needless to say, differs enormously. The natives of India cling to their primitive methods and customs with the most tenacious conservatism. They remain Oriental in spite of long permeation with European ideas. There are of course distinguished exceptions, and I need not remind this audience how prominently His Highness the Chairman has stood forth among the princes of India as an advocate of education, of social reform and of industrial progress. Some of the innovations due to British rule—such as railways and cotton mills—have to a certain extent affected the population throughout India, but probably British influence has not penetrated very deeply. To the British, and still more to the Colonial mind, the most unintelligible fact is the Indian's lack of any desire to "get on." He has no ambition to raise his standard of living, and his wants now, as in the past, are few and simple. This is the key to the whole economic position in India. External pressure may be breaking down caste in certain directions, but caste and family traditions and love of ease still preclude any eager pursuit of gain. Even wealthy merchants often confine themselves to strict necessaries, caring nothing for

the comforts and conveniences that even a poor European would require. It is true that there is a growing demand for certain European goods, but they are mostly in substitution for similar but dearer and inferior native articles. Despite apparent exceptions the broad rule is that the Indian has few wants and a low standard of comfort. Given this primitive economic condition, it is not surprising that the range of imported goods is small, that manufactures are in a rudimentary stage of development, and that they play a very minor part in comparison with agriculture, to which, in fact, they have always been closely subordinated. It is on the improvement of agriculture, indeed, that any considerable development of manufactures must depend. The agricultural population have now very little margin for the purchase of manufactured goods, nor will they have any until they can enhance the productive power of the soil. It has to be remembered, then, that for any period worth considering the tastes and the effective demand of the agricultural classes must be the dominant factors in industrial development.

The existing Indian manufactures are, roughly speaking, either the products of the ancient village handicrafts, or the machine-made products of mills that have grown up in the cities under European influence. That only 10 per cent. of the people of India live in towns is in itself a clue to the industrial condition of the country. Owing to their corporate connection with the village community and to their great numerical superiority over factory workers, the rural artisans still play a predominant part in manufactures. But though they know and can cater for the precise wants and tastes of their customers, their position is being undermined by the influx of finer and cheaper goods from British or Indian mills. With the growth of capital, the diffusion of education and technical skill, and the extension of railways, it is probable that modern methods of manufacture will more and more supplant the ancient rural industries. But before dealing with the factory industries, it will be well to note the effects that have already been produced on indigenous industries by the invasion of manufactures produced by modern processes. Perhaps I may say here that all general statements about a country so large as India must be accepted with caution, though I have endeavoured to generalise as accurately as possible from a great mass of detail.

The Decay of Handicrafts.

Ninety per cent. of the population depend on agriculture and on about 25 occupations closely associated with rural life. Hand-loom weaving is easily first, followed by carpentry, shoemaking, pottery, building, oil pressing, metal working, &c. These industries, supplying the simple needs of primitive communities, are conducted on traditional lines. Until lately the artisans have had little inducement to improve their work in quality or finish, and with a subsistence practically assured inventive power and mental concentration could hardly be expected. The industrial competition that is affecting handicrafts is increasingly from India itself. To the village weaver it is immaterial whether he is squeezed out by the Bombay or the Lancashire mills. Leaving the case of the hand-weavers for special notice, we may refer to the oil-pressers, whose production of oil for lighting purposes has been diminished by the invasion of cheap kerosine. The kerosine tin, even, plays a part in the displacement of ancient industries, for it is used for storing *ghi* instead of the bag made by the native leather worker, and it is also used for boiling water. The village shoemaker prefers to buy leather from the large modern tanneries rather than the inferior products of the many small native tanners, whose existence has thus become precarious. The shoemaker himself, however, is in many parts suffering from the importation of foreign shoes. The cheaper and less troublesome aniline dyes are superseding the native vegetable dyes in the widely distributed craft of dyeing and calico printing, and dyeing in factories has increased. In pottery, again, we find the influence of new processes, for earthenware vessels are giving way before cheap European glass and chinaware or enamelled ironware. European knives, axes, lamps, &c., are driving out the inferior productions of the village artisans. Iron smelting by crude and expensive methods is disappearing before the imports of cheap European iron and steel, which can be more easily shaped into pans, buckets, and agricultural implements. Coarse silks and woollens are to some extent being ousted by imported goods, as also roughly made glass and paper. Above all, the sewing machine, which is at work in every bazaar, must have saved much mere manual labour besides supplying new demands for made-up garments. It would seem from the last census report that in the

Punjab the village industries are far more firmly established than the urban ones, but taking India as a whole it is clear that the old order is changing and that several of the time-honoured village handicrafts are succumbing before the inroads of machine-made goods.

The Present and Future of Hand Spinning and Weaving.

After agriculture the hand-weaving of cloth is by far the most important occupation throughout India, two-thirds of all artisans being thus engaged. While the cotton mills, according to the 1901 census, employed about 186,000 persons, the hand industry comprised 3,369,000 spinners, weavers, dyers, &c., representing, with dependents, a total of 6,495,000. The Famine Commissions of 1880, 1898, and 1901 all drew special attention to the position of the weavers, and emphasised the importance of maintaining all crafts that afford a subsistence independent of agriculture.

The introduction of steam power naturally encroached first on the primary industries, diminishing the numbers occupied in ginning, cleaning, and pressing cotton, which are increasingly done in small factories, and in hand-spinning. Sometimes hand-spinning is referred to as a thing of the past, but the census shows 90,300 men and 509,200 women as engaged in it, while the agricultural returns estimate the local consumption of raw cotton as at least a million cwt. As an employment for the poorest class of women who can do nothing else or who spin between other occupations, hand-spinning may go on so long as yarn fetches any price above that of raw cotton. In villages remote from railways home-spun yarn can be sold at a profit, and although coarser, rougher, and less even than machine yarn, these very defects cause it to be preferred for wraps, quilts, &c., since it makes the cloth heavier and warmer as well as more durable than mill yarn of equal price. Only, however, in coarse descriptions can the hand-spun yarn compete successfully. Professional weavers rarely use it, preferring yarn from local mills for counts averaging 20 s, and English yarn for higher counts.

Hand-weavers exist in every Province and State, nowhere very flourishing, and usually hard pressed by the competition of machine-made cloths. This competition is not new, for 50 years ago, with a smaller population, the imports of cotton manufactures were valued at £5,400,000; but now the imports are £19,246,000, while to this must be added the output of Indian mills. In 1901 there were 1,836,400 male and 832,600 female hand-weavers, and only 172,000 were described as partially agriculturist. The great majority are hereditary craftsmen who usually exist in communities in considerable towns. Most of them are at the mercy of rapacious cloth merchants who finance them and take finished articles in repayment of advances. To a large extent the hand-looms and the mills supply different wants, the coarse and durable cloths of the former being preferred in many parts by field workers, while the more delicate products of these looms are bought by the wealthier natives. The mills compete with neither of these kinds of goods, but mainly supply plain cloths of finer texture to the middle classes. The exact condition of the hand-weavers appears to vary considerably in different parts. In Bengal, weaving is said to be decaying as a separate industry, and many weavers have taken to agriculture, mill-work, shop-keeping, or money-lending. English cloth is there replacing the stronger, and coarser native cloth, though the poorer Hindus from economy, and the more orthodox ones through conservatism, cling to the simple loom-made garments instead of following the ordinary well-to-do natives in adopting made-up garments in European fashion. In Assam, too, fine fabrics, more or less ornamental, are in good demand by the richer classes. The fortunes of hand-weaving in Madras seem very variable. Weavers of coarse cloths have the more regular work, but the competition of mill-made goods keeps their earnings at 3 to 6 annas a day, the latter rate implying long hours and the assistance of women and children. Weavers of fine cloths are said to make from 6 to 10 annas a day *when at work*. At the large weaving centre of Salem, the weavers make five or six annas a day by turning out ordinary cloths of 40 s to 80 s with old appliances, while at Coimbatore numerous artisans with antiquated looms weave yarns of 180 to 200 s into cloths and turbans, and, having plenty of work, earn eight annas and upwards. It is said that Lancashire cannot compete with the hand-made Madras handkerchiefs which are largely exported to England, and for which the demand is reported to be greater than the supply. In the Punjab mill-made cloths are used only by townsmen and well-to-do villagers, most people preferring the cheaper and more durable hand-made cloths. On the other hand, the machine-made cloths prevail in the United

Provinces, because neater, more even, and more attractive. The earnings of hand-weavers in this part of India are only 2½ annas a day, or less. In the Central Provinces ordinary articles of apparel (dhotis for men and saris for women), are woven by hand, though English cloth is preferred for shirtings, caps, &c., because cheaper and thinner. In Bombay Presidency the domestic handicrafts are chiefly important in saris and turbans, the best designs being those of Surat and Ahmedabad. Many fine hand-made goods are exported to Persia, Arabia, &c. The fabrics are either various scarf or plaid-like articles of dress which leave the loom ready for wear, or piece-goods for making up into clothing. All but a few conservative natives use the latter. Men's garments (dhotis) are usually mill-made, while women's saris and cholis (bodices) are largely hand-woven. In shirtings, long cloths, and sheetings the mills are supreme and turn out steadily improving qualities. Although some have drifted into the mills, many hand-weavers—chiefly Mohammedans—still practice their craft even in Bombay city. One of those whom I questioned at the Bombay Industrial Exhibition said that while there is a God above he did not fear the mill competition. Yet he admitted that saris had fallen in price from 6 to 1½ rupees—though part of the fall was due to the use of the cheaper machine-spun yarn. In Bombay 6 annas a day are said to be the usual earnings of a hand-weaver. All statements of earnings, however, are doubtful. One does not know if they are gross or net, if they are regular or not, and if they include aid rendered by the family. Again, prices of raw material fluctuate and the cost of living varies in different provinces, and in town and country.

For some years Mr. Havell and others have advocated the improvement of the antiquated hand-looms now generally used. Although hand-weaving is unquestionably decaying through the larger use of mill-made cloths as the railways extend, the industry is nevertheless widespread and has apparently enough vitality to last for many years. The rich and the poor still tend to prefer hand-woven cloths for different reasons, while the mill industry, though advancing, progresses at no extraordinary rate. It is a matter of grave concern whether the great majority of the hand-weavers, whose outturn is worth many crores of rupees, should be driven into agriculture after a prolonged period of grinding poverty or whether some action should be taken to better their position by improving their methods and machinery. For every mill-weaver there are said to be thirty hand-weavers, and as their standard of subsistence is low, they can compete more or less successfully with the machine-made cloths. Many believe that by the improvement of hand-looms India could produce most of the cotton goods now imported, or at least that an industry now decadent may be benefited if it cannot ultimately be saved. The native loom can be easily fitted with a fly-shuttle, with which weaving can be done twice as fast and cloth of much greater width produced. The fly-shuttle can be attached at a cost of 10 rupees, and a weaver can become expert in its use in one month. Some progress has already been made in popularising the appliance. The Bengal administration report for 1903-4 says that the improved loom is coming into more general use, and to it is ascribed the vitality in the hand-weaving of common cloths at Serampore. No fewer than 25 district boards in Bengal have taken steps to encourage the extended use of this loom. The Basel Mission factories at Calicut and elsewhere, employing about 900 weavers at 4 to 7 annas a day, have long made excellent cloth at a good profit with the improved looms. In the Jubbulpore jail it is found that the fly-shuttle loom is a conspicuous success. Recently a Japanese hand-loom is said to have been used with great success at Amritsar. The Madras School of Art has found by long experiment that fine cloths of 100 to 120s can be made with the improved loom, while even finer yarns can be woven if a modern warping and sizing plant be combined with it. The improved loom requires a better warp owing to the extra strain. But, generally speaking, the fly-shuttle is no better than the ordinary one for finer cotton and silk goods, except in the case of wide fabrics, though it is excellent for common cloths, such as sheeting and towelling. In opposition to the fly-shuttle loom it is argued that too much exertion is required to work it, and that after learning how to use it people revert to the old loom. But this is not universally true.

Need for Inquiry into Handicrafts.

In view of the decay of handicrafts, it seems probable that many more people are passing from these occupations into agriculture than are passing from agriculture into factories. If cloths now hand-woven were all made in Indian mills a much smaller number

of operatives would be required. The whole English cotton industry employs only 606,000 persons, and all the cloth needed in India could probably be produced in Indian mills by less than 1,500,000 workers. The growth of mills will not tend, then, within any moderate period, to diversify employment. It seems desirable that an inquiry should be made concerning Indian handicrafts. Every statistician knows how unsatisfactory is a census of occupations when taken as part of a general census. By means of a special industrial census it could be ascertained how many persons are wholly or partially engaged in the various handicrafts, how far such industries are suffering from goods made by modern processes in India or abroad, what measures could be taken to revive them by special instruction, or by the introduction of improved appliances, and what are the earnings and general condition of the artisans. With regard to the proposed adoption of improved hand-looms, there seems need to ascertain what is the best kind for ease and effectiveness of working, and what facilities, if any, could be afforded for the purchase of improved appliances by a system of advances. It may also be worth while to inquire how far electricity can be applied to hand-looms in the manner adopted in some industrial centres in Europe. Although it is probable that the hand-weaving of regular articles of trade on a large scale will ultimately disappear, leaving only a remnant of the original industry for producing special articles for limited markets, in which the power-loom cannot compete, it seems essential that the weavers, for social as much as for economic reasons, should receive practical assistance in tiding over this period of stress.

The Growth of Factory Industries.

The development of factory industries worked by steam power on European lines has been very gradual, and even now none besides cotton and jute employs as many as 20,000 persons. This slow development has been due to various causes—to the use of hand-made articles, to the large imports of cheap cotton goods and metal wares, and to the lack of industrial capital and enterprise, of business managers and skilled operatives. The progress in the chief manufactures, though not remarkable, has been steady, and increasing demands for home and foreign consumption are being met. Small beginnings, offering considerable promise, have been made in a variety of industries throughout the country. In Appendix I. will be found a list of the manufacturing industries of the different provinces. The list may at first sight appear formidable, but many of the industries are very little developed. Bengal and Bombay are by far the most important manufacturing provinces, and they are followed by Madras and the United Provinces. Indian mills are handicapped by the high charges for financing, and the heavy cost of maintenance. Their machinery and stores have to be imported from England, and their coal has usually to be transported over long distances at excessive rates of freight. Labour is as dear as in Europe, because it is unskilled and inefficient. The necessity of European management is another important element of cost. On the other hand, the mills generally have cheaper raw material, produced more or less on the spot, and as against imported goods they enjoy the natural protection conferred by nearness to the consuming markets. Up-country cotton mills especially profit by the proximity of raw cotton on the one hand and a large body of consumers on the other. Climate is yet another element to be considered in a country possessing such variety as India. The humidity of Bombay gives its cotton industry an advantage over that of Calcutta.

Industrial Centres.

As the modern industries have grown up under British influence and guidance even where, as in Bombay, they are now mainly in native hands, it is natural that the great seaports, the provincial capitals, and the railway centres should be the principal seats of manufactures. Industrial cities attract immigrant workers, who leave their women-folk behind; hence a large proportion of "foreign-born" men and a low proportion of females furnish a rough test of the industrial importance of a city. The following Table illustrates the importance and progress of the chief manufacturing cities:—

	Population, 1901.	Increase per cent. between 1872 and 1901.	Proportion of foreign-born per 1,000.	Proportion of females per 1,000 males.
{ Calcutta	848,000	34	657	507
{ Howrah......	158,000	87	659	577
Bombay	776,000	20	766	617
Madras	509,000	28	315	984
Rangoon	235,000	138	680	419
Delhi	209,000	35	284	817
Cawnpore	197,000	61	381	772
Ahmedabad	186,000	55	290	910
Amritsar	162,000	20	264	743

Calcutta has become the centre of a vast industrial area, and the banks of the Hooghly are studded with tall chimneys. In the suburb of Howrah about 10 per cent. of the people depend on jute mills and presses, and over five per cent. on machinery and engineering workshops. In Bombay and Ahmedabad cotton mills support about 15 per cent. of the population, while Bombay, whose inhabitants have declined greatly in recent years owing to plague, has also many other industries. The rice mills of Rangoon give support to 11 per cent. of its population. The importance of Cawnpore as a railway junction and its production of large quantities of stores for Government have made it a great industrial centre.

Capital and Enterprise.

Before dealing specifically with the chief factory industries it is well to consider the general conditions that govern the more advanced manufactures. It has been said over and over again that India lacks industrial capital because the natives hoard their money instead of investing it in banks and joint stock companies, and because British capital is little attracted by Indian investments. It is unfortunately true that the traditional mistrust of exhibiting material wealth, a feeling inherited from the days of extortionate rulers, still prevents the natives from adopting means of investment that would enormously enlarge their own wealth and that of the country. A long course of education may be necessary before such habits are changed. Those who do not hoard can at present reap much larger profits from ordinary money-lending than from industrial undertakings which may involve considerable risk, and the native is rarely satisfied with the low rate of interest which British capital yields. But though an enormous increase in capital is required before India can be adequately developed, there seems to be no present lack of capital in established industries which have grown up under European supervision, such as cotton, jute, tea, &c. For jute two crores of new capital were forthcoming in the eighteen months to December, 1904. These particular industries, then, obtain capital easily, and rupee investments have been specially marked in cotton and jute. The fund on which industrial enterprises mainly depend for initiation and maintenance is the capital and deposits of the three Presidency banks and eight Indian banks, though the exchange banks also contribute something to the financing of Indian business. This fund has greatly increased in the last ten years, and was recently estimated by Mr. O'Conor to amount to £30,000,000. The comparative shortage of money in any quantity entails high interest (about 8 per cent. as a minimum up-country) even when good security is provided. The Indian banks are generally prosperous and with one exception have paid regular, and mostly high, dividends for several years. Signs are not wanting that capital is now flowing into India more freely. The fixity of exchange has safeguarded gold investments since 1897 and has done away with that uncertainty which so long crippled enterprise. The financial position of the Government is extraordinarily sound. The revenue is large and increasing, the assets greatly exceed the debt liabilities, railways and irrigation works have enlarged prosperity, and property is secure from internal disorders as well as guaranteed against external invasion. The steady repurchase during the last ten years of rupee stock held in England and the fact that natives hold £34,000,000 of Government rupee securities (an increase of 63 per cent. in ten years) are of striking significance. A prominent Calcutta banker said recently that *if India got fair play from England* money would never be difficult to find for any properly managed undertaking.

It is probable that India now needs enterprise more than capital. Ages of repressive conservatism have left their mark on the Indians, who generally lack the self-confidence, individuality, and force of character essential to enterprise, and are easily discouraged by failures. They are timid, and they do not sufficiently advertise and push their wares. In mills owned by natives European managers are generally employed, as native managers lack enterprise and initiative, fear responsibility, and cannot cope with unforeseen difficulties. Indians, therefore, usually follow in the lines traced out by Europeans as regards the advanced industries, and European supervision and control are generally requisite. Again, many educated natives despise industrial and commercial pursuits. Their inability, as a rule, to form joint-stock undertakings with success should also be noted, though in Bombay many companies have been formed. The last Punjab census report dwelt on their incapacity to combine except perhaps when they belong to the

same caste, and this inherent lack of combining power, due to the same spirit of mistrust or exclusiveness, has deterred natives from industrial association in Bengal and Madras. In Bengal they are said to invest willingly in enterprises controlled by Europeans, such as jute mills. In spite of all drawbacks, however, the paid-up capital of joint-stock concerns in India (which are in addition to numerous large joint-stock companies with sterling capital having head offices in England), has increased by 42 per cent. in ten years. Nearly one half their paid-up capital of £26,000,000 at the end of 1903-4 was invested in presses and mills for cotton, jute, &c., while 10 per cent. was in tea, coffee, and other plantations.

The Labour Supply.

At the recent conference of Chambers of Commerce in Calcutta great stress was laid on the industrial difficulties resulting from scarcity of labour, which probably arises from various causes. On the one hand, famine and plague have cut off large numbers of landless labourers, while the increasing demand for labour by railways, irrigation works, mills, mines, plantations, &c., has absorbed an increasing proportion of the labouring class. In Northern India, at any rate, the demand now exceeds the supply, and the normal expansion of existing industries is handicapped, to say nothing of new industries. The immobility of labour is remarkable, though there is some migration from the United Provinces into Bengal, from Bengal into Assam, from Madras into Burma, &c. The migration from country to town is slow and difficult, and hence an unsatisfied demand for labour in the chief industrial centres. A rise in wages does not easily tempt a native to change his occupation or abode. Caste and family considerations bind him to the soil. Content with what suffices for food and raiment, the husbandman does not readily quit the fields for the irksome, regular life of a factory, though his earnings might be greatly increased. At Cawnpore, the supply has fallen off, in spite of a rise in wages, and the incidental advantages of cheap houses, short hours, medical attendance, &c. Increased wages may often mean a less amount of work, for, having a surplus in hand, the operative after working for a few months may take a long rest in his village, where subsistence is very cheap. Increased demand for labour often causes deterioration in quality. The ambition of the natives is usually to get good pay, not to do good work, and they show little growth in skill, though some advance is perceptible in the Bombay cotton mills, where a class of factory operatives is growing up. Many operatives there stay in the mills all their lives, and bring up their children to factory work. India, then, is suffering from a shortage of labourers, and from the fact that the operatives lack energy and skill, and fail to respond to the inducements that higher wages offer in Europe. At a typical Bombay cotton mill that I visited under the skilled guidance of Mr. Engel, the Inspector of Factories, the men earned on the average 5s. a week and the women 1s. 6d. a week. If the wages seem low the standard of work is also low—physique, climate, degree of intelligence and other factors modifying the power of output. The mill operatives are drawn not only from the landless labourers, but also from the poorer ryots and the hand-weavers. Men are often employed on work that women would do in England. They take little interest in their work, and have little ambition to excel, they cannot assume responsibility, and there is much waste. They require also to be humoured in many ways. Different castes have different meal times and the men break off thrice a day to go outside and smoke cigarettes. Their work is irregular and they usually have a month's holiday besides Sundays. Their holidays are partly for religious festivals, partly for work in their villages during seedtime and harvest. Owing to these circumstances about five operatives are required where one would be employed in England, and consequently the cost of labour is at least as great as in England, which shows that Indian labour—once feared by English trade unionists—is not really a source of danger. Factory work is popular in so far as the wages are much above those earned by people of the same class in other pursuits, and the general condition of the workers is prosperous. For housing the cost is about 2s. to 2s. 6d. a month, for clothing about 2s. a year, while subsistence is obtainable for a penny a day. The scarcity of labour has forced up wages, and the rise seems likely to be permanent. In the jute industry mill extensions are being deprecated on the ground of shortage of labour, while plague has affected the supply in Bombay and the United Provinces. In Madras the supply seems ample, but there is a chronic unsatisfied demand in the Assam tea-gardens.

Factory Legislation.

The Indian Factory Act of 1881, as amended in 1891, fixed the minimum age for child labour at nine years, and the hours of work at seven, while women's hours were restricted to eleven with intervals of 1½ hours. The hours of adult males, as in England, are nominally unrestricted, but hours of rest and holidays are regulated for all workers. Ample holidays are taken, especially in hot weather, and Sunday closing is compulsory with some exceptions. In 1902 the number of factories liable to inspection was 1,389, mostly in Bengal and Bombay. In 60 of these, chiefly jute presses and printing presses, steam power was not used. Cotton mills and presses constituted about 60 per cent. of all the factories worked by steam. Rules regarding ventilation, sanitation, water supply, the fencing of machinery, &c., are well observed, while the number of accidents is not large. Many millowners go far beyond the requirements of the Act, everything being done to make factory life attractive to the somewhat unwilling operatives.

The Supply of Power.

Only in recent years have the Indian coal-fields yielded sufficient to make India self-supporting. The railways consume 30 per cent. of the present output of 7,500,000 tons, while mills, steamers, &c., use the remainder. The increased proportion of coal consumed otherwise than by railways points to some growth in industry, but in 1903 production was checked owing to the supply exceeding the demand. Electric power is now being employed, and there has recently been a brisk demand for installations in the Bombay cotton mills. Calcutta and Bombay have electric power stations, and a large scheme is on foot for supplying it to the Punjab. The transmission of electric power from the Cauvery Falls to the Kolar gold-fields for various mining and metallurgical works is an admirable illustration of what may be done elsewhere.

The Principal Manufacturing Industries.

The various factory industries may be classified as follows :—

(1.) *Manufactures proper*, conducted for the most part by means of steam-power on European lines. They include the spinning and weaving of cotton, jute, wool, and silk, dyeing, paper-making, coir manufactures, leather manufactures, brewing and distilling, rope-making, flour milling, oil milling, sugar refining, printing, shipbuilding, engineering, iron, steel, and brass foundries, electricity supply, gas supply, manufacture of ice, aërated waters, perfumery, &c.

(2.) *Manipulation or Preparation of Agricultural, Forest, or Animal Produce.*—This head comprises tea and coffee production, ginning, cleaning, and pressing of cotton, jute pressing, indigo manufacture, husking and cleaning of rice, tobacco manufacture, silk filatures, opium manufacture, lac manufacture, saw mills, preparation of coir and copra, tanning and dressing of hides and skins, fish-curing, bone-crushing, &c.

(3.) *Utilisation of Minerals.*—Refining of petroleum and manufacture of oil products, salt and saltpetre refining, chemical and alkali works, lime and cement works, making of paints and colours, brick and tile-making, pottery, jewellery, copper, brass, and tin-smiths' work.

The above classification aims at being logical, but no division can be strictly logical, and for practical convenience I shall single out only a few important manufactures for special treatment. In Appendix II. will be found a list of the chief industries with the numbers employed according to the volume of Financial and Commercial Statistics, issued in 1904, and the census returns for 1901. The former are admittedly incomplete, while, owing to difficulties of enumeration, the census figures can only be regarded as approximate.

The Cotton Industry.

Considering the wide-spread production of raw cotton, it is not unnatural that cotton manufactures have long flourished in India, and that Indian cotton goods were famous in England before the Lancashire cotton industry began. Improvements in machinery and the use of steam power in Europe destroyed India's former supremacy in textiles, but being now equipped with the latest appliances she is endeavouring to win back her home market for yarn and piece goods. Cotton being one of her staple crops, India can save the freight, commissions, &c., that England has to pay for importing raw material and re-exporting this material in a finished form. But besides cheap cotton, the industry needs cheap fuel, machinery, and stores, an adequate supply of skilled labour, cheap land and buildings, capital at low interest, and large and stable markets.

The Supply of Raw Cotton.

The cotton area, which exceeded 17½ million acres in 1890-1, declined for some years owing to bad seasons, but has increased to about 19 million acres in 1904-5, as against 18 million in 1903-4. The annual yield of fibre probably ranges from about 3 to 3½ million bales (of 400 lb.), and it is roughly estimated that about 40 per cent. is exported, 48 per cent. used in the mills, and 12 per cent. consumed locally. The crop, then, is a most important and valuable one. England, once the chief buyer of Indian cotton, cannot now spin the short-stapled fibre to advantage, and the principal purchasers to-day are Japan—by far the largest—and the countries of Continental Europe. For a century endeavours have been made to improve the quality of Indian cotton, and owing to recent shortages of American cotton and high prices, these efforts are being renewed. The agricultural departments aim at improving the out-turn by improved cultivation, by the introduction of new varieties, and by the selection and hybridization of indigenous plants, which are expected to be more fruitful than the growth of exotic varieties. The latter, however, are being tried in Sind on irrigated soil. So far as the cotton fibre has deteriorated, it is probably due to continued cultivation of the same strains of seed, to carelessness about seed selection and cultivation, and to impoverished soil. The ginning mills have supplied cultivators with very mixed seed, which, when grown regardless of the character of the soil, has yielded inferior fibre. But there are other reasons. Inferior varieties are grown extensively because they can be produced on soils unsuited to finer varieties. Moreover, the coarse, short-stapled cottons are hardier, are less liable to injury from insects and bad seasons, can be planted later, mature earlier, and give a larger yield, which compensates for the lower prices they fetch. There is always a crop of such cotton, and it is in constant demand both for home consumption and for export. The cultivator who wants not a long-stapled cotton but a paying crop, has deliberately substituted the inferior variety, and he cannot be blamed for thinking of his own needs rather than Lancashire's. He will not grow finer cotton to meet an intermittent demand at very fluctuating prices. The largest and most reliable purchasers of Indian cotton—the Indian mills and the Japanese—do not require a long-stapled cotton for the production of their coarse yarns.

The ginning, cleaning, and pressing of cotton by steam have increased, and 900 factories, mostly native owned, employ 75,000 people in this work. More than one-half are in the great cotton areas of Bombay and Berar. Complaints are often made of the increasing adulteration of cotton, and the re-enactment of the Cotton Frauds Act has been suggested in order to keep bad cotton from being introduced into districts that grow good cotton. But the Act of 1863 was repealed in 1882 on the ground that it was not only ineffective, but often punished the wrong persons, while it also did harm to the industry.

The Growth of the Mills.

Considering that cotton mills have existed in India for 50 years their progress has not been extraordinary, though, as the following figures show, they have steadily advanced in the last 20 years.

	1883-4	1893-4	1903-4
Mills	74	137	204
Spindles (000 s)	1,895	3,540	5,213
Looms (000 s)	16	29	46
Persons employed (000 s)	62	131	186

It will be noticed that the increase in spindles was roughly the same in each decennium, though looms increased faster in the second. The increases in the 20 years were 176 per cent. in spindles and 186 per cent. in looms. In 1903-4 the mills comprised 113 exclusively spinning, 5 exclusively weaving, and 86 both spinning and weaving. The *employés* were 64 per cent. men, 20 per cent. women, and 16 per cent. children. As compared with English mills the percentage of men employed is very high. All but 33 of the mills are owned by joint-stock companies, and the paid-up capital and debentures of the mills are estimated at £10,500,000, by far the greater part being rupee capital, the investments of which are increasing. Indeed, native capital flows into cotton much more freely than into any other manufacturing enterprises. The amount of capital invested in weaving is considerably less than in spinning.

The most numerous mill owners in Bombay and Ahmedabad are the Bhattias, who own more than half the mills, the rest being owned by Englishmen, Parsis, Jews, and Mohammedans. Up-country mills are generally native-owned, and the important Cawnpore mills, though undertaken by Europeans, have been financed by natives.

In recent years the cotton industry has suffered great vicissitudes, especially at its head-quarters, Bombay City. Apart from recurring difficulties due to financial short-comings, and to faults in management and equipment, there has been a succession of special troubles. The outbreak of plague drove the operatives from the city in thousands, and the high plague mortality has made labour scarce; in 1896-7 and again in 1900-1 drought curtailed enormously the supplies of raw cotton, while famine reduced the purchasing power of home consumers; and political disturbances in China with fluctuating exchanges injured business with that great consuming country. In consequence of these troubles many mills have gone into liquidation, reduced their capital, or undergone reconstruction. At the same time the industry has expanded by the erection of new mills, and the quality of the products has improved. With cheaper raw material, a steadier demand for yarn in China, and a well-sustained home demand, the mills are once again in full operation. The more extensive weaving of cloth is a source of strength to the yarn market. Finer yarns are required for cloth made in the mills, and it is better to produce these than the coarser yarns exported to the fluctuating China market.

About 70 per cent. of the mills and the spindles and 76 per cent. of the looms are in Bombay Presidency, and the majority of these are in Bombay City, but Ahmedabad is gaining on the capital, because, being in the midst of a great cotton-growing region, it obtains its raw cotton more cheaply. In ten years Ahmedabad has increased its spindles by 126 per cent. and its looms by 76 per cent., and it shows great promise of further development. After these two cities, Sholapur is the chief spinning centre and Broach the principal weaving centre in the Presidency. Nagpur (Central Provinces) possesses 1,580 looms, while Cawnpore, with 3,215, and Madras, with 1,747 looms, monopolise the power-loom weaving in their respective provinces. In Appendix III. is a Table showing the relative importance of the different provinces in the cotton industry. During the last ten years the growth in spindles and looms has been proportionately greatest in India outside the Bombay Presidency. These up-country mills supply yarn to local weavers, and sometimes cloth for local consumption. Many of the Bombay mills have dye-works, and a few do bleaching. These processes require water, the high charges for which by the Bombay Corporation have been a subject of complaint. The growth in the export of cotton goods, as shown below, furnishes evidence of the development of the industry.

	1883-4	1893-4.	1903-4.
Cotton twist and yarn—million lb.	50	134	252
Cotton piecegoods—million yards	56	73	76

Cost of Production.

We have dealt generally with the question of cost of production in Indian mills, but the cost of cotton production requires special notice. The cost of sites is not serious in Bombay, and is negligible up country, but the cost of buildings and equipment in India, as compared with Lancashire, is 2½ times greater. Indian mills have up-to-date English textile machinery, on which in the last three years alone over £2,600,000 has been expended. Wages amount to 8 to 10 per cent. of the value of yarn, and 20 per cent. of the value of cloth. As already shown, the cost of labour is as great as in England, for the operatives are more numerous though less well paid, require more space, are unskilful, and make much waste. Mill stores are dearer than in England by the cost of freight and 10 per cent. commission to agents. Country coal is fairly good, but Bombay is far from the mines and transport is very dear, so that coal is 50 per cent. dearer than in Lancashire. Capital, again, requires 6 to 7 per cent. for interest as against 3½ to 4 per cent. in England. In recent years there has been warm discussion about the commissions paid to agents for managing the mills, purchasing all requisites, selling yarn, &c. A system grew up of remunerating managing agents by a commission of ¼ anna per lb. on every pound of yarn spun without reference to profit, and it had a certain advantage in earlier days by tempting unenterprising capitalists into the industry, but it was also an incentive to over-production involving loss, as the agents were anxious to produce as many pounds as possible regardless of the selling price. The ¼ anna system is still retained in some mills, but in others the agents have accepted the much fairer basis of 10 per cent. commission on profits.

The Cotton Duties.

Complaints are still occasionally heard about the cotton excise duties, and some mill-owners contend that these duties enable the hand-made cloths, which are not subject to them, to compete successfully with the factory cloths. Others, however, admit that a duty so small as 3½ per cent. *ad valorem* can

give but slight appreciable advantage to the hand-looms, and the position of the hand-weavers, as we have seen, is far from flourishing. Moreover, the taxation of hand-made cloths could only be effected by the taxation of the Indian and English yarns that hand-weavers most widely use, and probably no mill-owner would welcome such an innovation. It is felt in India that if any fundamental fiscal changes take place in England India can legitimately claim a free hand in modifying its tariffs. One mill-owner even favours a 10 per cent. import duty, with a corresponding excise duty, on the ground that consumers would be driven by the dearness of imported cotton goods to buy the cheaper Indian cloths. Needless to say, a 10 per cent. import duty without the excise would be infinitely more acceptable.

Production of Cotton Yarn.

The chief business of the cotton mills is the production of yarn for export, for use in power-loom weaving, and for consumption by hand-weavers. The following table shows the production during 1903-4 in British India, distinguishing higher from lower counts (in millions of lb.) :—

	Counts 1 to 20.	Counts over 20.	Total.	Per-centage of higher counts to total production.
Bombay	327·4	87·5	414·9	21
Central Provinces and Berar	19·9	4·7	24·6	19
Madras	23·8	4·9	28·7	17
Bengal	43·8	2·7	46·5	6
United Provinces and Ajmer	29·5	0·4	29·9	1
Punjab	11·6	0·04	11·6	0·3
Total	456·0	100·2	556·2	18

Native States in 1903-4 produced 22,568,000 lb. of which 18 per cent. consisted of counts above 20 s. Yarns of the higher counts have increased from about 14 per cent. of the total Indian yarn production in 1897-8 to 18 per cent. in 1903-4, and this growth was specially marked in the last year, which showed an increase from 12·5 to 16·5 million lb. in counts 31 to 40 alone above 1902-3, while the lowest counts declined. In the higher counts Ahmedabad has increased faster than Bombay City, while Madras, which spins largely for the local market, has advanced in counts 21 to 30. The predominance of Bombay, the Central Provinces, and Madras in counts above 20 is remarkable, and their output is increasing.

In yarn production the most important and fluctuating element is the cost of raw cotton. The coarser Indian cotton is specially adapted for spinning yarns up to 20 s, though Hubli, Broach, and Dhollera can be fairly well spun up to 42 s. Average cotton can be spun up to 32 s, and Bombay mills have practically ousted imported yarns up to 24 s. The lack of skill of the operatives tells most in spinning higher counts, as they make a great deal of wastage, which has to be worked up again.

The following figures show the competition in 1903-4 between Indian and imported yarns, which are mainly coloured (in millions of lb.) :—

	Indian yarn.	Imported yarn.
Counts 1 to 20 ...	474·5	2·5
„ 21 to 30 ..	86·8	4·0
„ 31 to 40 ..	16·5	14·5
„ over 40 ..	0·9	4·8
Total	578·7	25·8

To the imported yarn must be added 2·2 million lb. of unspecified counts. It is noteworthy that the Indian mills now produce more of counts 31 to 40 than are imported, though these form the bulk of the English yarns. It is not surprising, therefore, to find that yarn imports have declined from an average of 48·4 million lb. in the five years ended 1898-9 to 35·5 million lb. in the quinquennium to 1903-4.

The question of the disposal of the imported and Indian yarns is important in its bearing on the position of hand-loom weavers, who use most of the imported yarn, though a good deal appears to be used by the mills, especially up-country. The following figures are for 1903-4 :—

	Millions of lb.
Imports of foreign yarn (deducting re-exports)	27
Production of Indian mills	579
Total amount of yarn available..	606
Less exports to China, &c..............	252
Balance for Indian power and hand looms	354

The exact proportion in which this balance is distributed between the power and hand looms cannot be ascertained, but the latter are supposed to absorb 35 per cent. of the yarn

produced in the mills (or 203 million lb. in 1903-4), together with most of the imported yarn. Probably the hand-looms consume 50 per cent. more yarn than the mills in addition to the hand-spun yarn made locally. These figures, however, can only be taken as approximate.

About 94 per cent. of the yarn exports go to China, which has a large demand for counts up to 20 s, while dealings with Persia and Turkey have increased. In China, India's chief competitor is Japan, but in recent years India's spindles have increased faster than Japan's. As Japan depends mainly on Indian raw cotton, there is great scope for the extension of Indian yarn production by the working up of the cotton now sent to Japan.

THE PRODUCTION OF COTTON CLOTH.

In weaving, the Indian mills have to withstand the competition of (1) the hand-weavers, who especially compete in saris; (2) the Lancashire mills, which compete chiefly in the coarser grey goods, inasmuch as India does not largely produce piece-goods like the finer unbleached or the white and coloured goods that are imported; (3) the Continental mills, whose contributions, mainly coarse and inferior goods, are small in proportion to the total import of cotton manufactures, though not inconsiderable in proportion to the total Indian mill output. Indian mills appear to be making headway against all three competitors. Some mill-owners, however, fear the competition of hand-woven cloth, the home consumption of which has been recently estimated at thrice that of power-loom cloth. This is not improbable, if it be remembered that some of the latter is exported. The average production of a power-loom is estimated at 12 lb. of cloth a day, as against 2 lb. from a hand-loom, though the latter cloth is said to last thrice as long, which partly explains the preference for hand-woven cloths by certain classes of the people. We shall deal directly with foreign competition in Indian manufactures.

A great expansion in weaving has occurred during the last two years, a few Bombay mills with modern plant having made remarkable progress. An addition of 5,000 looms is expected in 1905. Mill-owners have discovered that cloth production for the long-neglected home market is less risky and more profitable than yarn production for China, especially when yarn prices are low and those of raw cotton high. The absorption of yarn by the mills not only relieves the China yarn market, but the output of Indian cloth carries the process of manufacture a stage further and enables India to compete against the coarser imported cloths. An enlarged home and foreign demand in 1903-4 occasioned an advance in prices though production was much greater.

Indian mills produce mainly grey goods, of which the output in 1903-4 was as follows (in million of lb.):—

Shirtings and longcloths	39·2
Dhotis	26·7
T-cloths, domestics, and sheetings..	19·1
Chadars	14·1
Other sorts	12·4
	111·5

The quality of the output has improved, and recently the production of longcloths has greatly advanced. Grey goods represent 81 per cent. of the cloth production, but more rapid progress has taken place recently in white, fancy, and coloured goods, which, however, are not yet largely produced owing to the difficulties of bleaching and printing. The proportion of woven goods other than grey is highest in Madras, where excellent cloth is made, including khaki for native troops. There has also been progress in hosiery, which is made only in Bombay, being produced in the cloth mills or in small separate factories. Weaving is concentrated in Bombay to an even greater extent than spinning, the Presidency mills turning out 86 per cent. of the cloth woven in British Indian mills. The expansion at Ahmedabad from 19·1 to 28·7 million pounds in the two years to 1903-4 is remarkable. This city weaves a limited quantity of high-class cloths, such as dhotis, from fine English yarns. Lower cost of production and a favourable situation enable Ahmedabad to compete keenly with Bombay City in the supply of cloth to Northern India.

The following figures (in millions of lb.) show that the production of woven goods in British India has increased 50 per cent. in the last six years:—

	Grey.	Other kinds.	Total.
1897-8......	80·0	8·0	88·0
1903-4......	105·8	26·2	132·0

In addition, the production of Native States has grown from 3·3 to 6·2 million lb., a greater proportionate increase than in British Indian mills. But the total production of Indian cloth is only equal to about 25 per cent. of the imported cotton manufactures.

The production of piece-goods in the five years to 1903-4 averaged 513 million

yards, while the exports of piece-goods averaged 71 million yards, some portion of which, however, consisted of hand-made cloths. In 1903-4 there was an increase in cloth exports, after a considerable period of inelastic trade. A considerable part of the exports consists of dyed or printed goods from Madras, which go increasingly to the Straits, Ceylon, Aden, &c., while grey goods are sent chiefly from Bombay to Aden, Abyssinia, and East Africa. Cloth exports to China have declined, but there is a growing market in the Levant. On the whole, the outlook for Indian cloth production is excellent, both in foreign markets and in India, where the fashion of wearing more clothes is increasing with the growth of prosperity.

FOREIGN COMPETITION IN COTTON GOODS.

Cotton manufactures constitute 34 per cent. of all Indian imports. The imports of cotton piece-goods taking five-year averages, have been as follows (in millions of yards):—

	1889-90 to 1893-4.	1894-5 to 1898-9.	1899-00 to 1903-4.
Grey (unbleached)	1,223·5	1,209·8	1,204·5
White (bleached)	368·6	418·6	469·7
Coloured, Printed, and Dyed	374·2	351·5	430·6
Percentage of grey goods to total imports	62	61	57

There has been a decline, though not a serious one, in the grey goods with which Indian mills compete most keenly. England supplies 99 per cent. of all grey goods. The import of white goods has decidedly increased, probably because they are made of superior material. Over 98 per cent. are imported from England. Coloured goods also come from England to the extent of 96 per cent., the rest coming chiefly from Continental Europe. About 10 per cent. of the imports of coloured goods are re-exported. Foreign competition with England is most apparent in cotton hosiery and miscellaneous cotton goods, and the slackness of England and the activity of the Continent are hard to explain. British piece-goods are found all over India, and are especially preferred by the middle-class natives, because they are finer and cheaper, even if less durable than native cloths. The late Sir George Cotton, who had wide experience of India and Lancashire, was of opinion that India could never compete in finer goods, because the English mills are better equipped for fine counts, while British labour is more skilful and efficient. The sizing percentages of English goods cannot be approached by the Indian mills, which use much less size in the weaving process, though some is added later. England, too, has other advantages in cost of production. To compete with English mills India would have to import fine cottons and many other requisites, and only one-sixth to one-fourth of the value of the product would really represent India's share in wages and profits. To manufacture even the grey cloth now imported India would have to double her existing mills. Probably, then, India will long continue to buy the fine and cheap goods of Lancashire.

JUTE MANUFACTURES.

We turn from cotton to a somewhat smaller though an even more successful industry, viz., the manufacture of jute. Power-looms for this purpose were first erected in 1857, but for a long period jute was largely produced by hand-looms. This handicraft for making sacking and ropes has now decayed, and the industry is mainly a factory one.

Calcutta is the great centre of jute production, and except one mill at Cawnpore and another in the Vizagapatam district (Madras), all the mills are in Bengal, and most of them in the vicinity of Calcutta. All but four of the mills are worked by joint-stock companies. The growth of the industry in the last 20 years is shown in the following Table:—

	1883-4.	1893-4.	1903-4.
Mills	23	27	38
Nominal capital	£1,357,000 Rs.115 lakhs.	£1,160,000 Rs 231 lakhs.	£2,263,000 Rs.403 lakhs.
Spindles	112,650	191,228	376 718
Looms	6,139	9,180	18,406
Employés	47,868	68,291	123,869

It will be seen that while the industry increased about 50 per cent. in the first decennium it advanced 100 per cent. in the second. Sterling capital has increased, with fluctuations, by 67 per cent., while rupee capital has steadily grown by 250 per cent. in the 20 years, and now exceeds the sterling capital. As in cotton, so in jute, the native capitalist is tending to subscribe the new investments of capital. Of the *employés*, 81,700 are men, 21,140 women, and 21,000 children. The jute workers are well paid and live in healthy surroundings, and as their wages afford a large margin beyond the cost of subsistence they take long holidays—two months or more. Jute has made thousands of workers prosperous, and to the high wages of jute opera-

tives has been partly ascribed the want of progress in cotton and other mill industries in Bengal. On January 1st, 1905, the jute looms numbered 21,318, and about 2,000 more are to be put in this year. Some fear that the mills are being too rapidly extended. The supply of labour is short, while high pay makes the operatives independent. Competition for labour due to extensions raises wages, while a greater demand for raw material enhances the cost at the same time that a larger output of goods diminishes their price. But so long as a large quantity of raw jute is required abroad and the foreign demand for bags and cloth is unabated, which seems likely for a long time, over-production need hardly be feared, though extensions should be gradual if the present high rate of profit is to be maintained.

Calcutta is now the centre of the jute manufacture of the world, and naturally so as it is near the area which has a practical monopoly of the production of raw jute. Calcutta is favoured not only by its proximity to the sources of the raw material, but by ample supplies of coal from the adjacent Bengal mines. One freight only has to be paid to foreign markets as compared with two by Dundee, and there is a constant demand for hessians and gunnies, to which the Calcutta mill owners restrict their energies. The relative importance of Dundee has greatly diminished, her share of the Indian crop being now only about 20 per cent., instead of, as formerly, almost the whole crop. The Calcutta mills are said to be better equipped than most of the Dundee mills, for owing to recent extensions, their machinery is more up-to-date, and they gain by combining weaving and spinning. Having cut Dundee out of most of her old markets in heavy goods and common hessian cloth, Calcutta gradually ceases to compete with that city, which now produces mainly special kinds of yarn and piece goods. In Europe jute is largely used for making carpets, curtains, and shirtings, and for mixing with silk and wool. Apart from England India's chief competitors in jute manufactures are Germany, France, Austria-Hungary, and Italy, which secure their home industries in jute by protective tariffs. In Germany there is a strong jute trust.

Although the demands for raw jute for manufacture and for export are rapidly increasing, the area under jute has expanded but little in recent years. About 2,850,000 acres are under the crop, and the yield has varied in the ten years to 1902-3 from about 5,000,000 to 6,500,000 bales (of 400 lb.). Crop variations render the jute trade very speculative. On the whole, there has been an upward tendency in raw jute prices, amounting to about 25 per cent. in the last 20 years. The estimated total out-turn for 1903-4, viz., 7,462,000 bales, was roughly distributed as follows: exports 3,788,000, mill consumption 3,144,000, local consumption 500,000, and stock 30,000 bales. An increase in the jute area is a matter of considerable importance, for unless India increases her acreage there may be a shortage of supply in the world market that will either stimulate cultivation elsewhere or the use of substitutes. The pressing of raw jute, a separate industry, occupies 155 presses, and employs 21,000 persons.

A recent official report on the alleged deterioration of jute suggests that the plant should be cut for fibre before it is dead ripe, and that liberal cultivation, and probably also rotation of crops, ensure a better out-turn of fibre. Adequate manuring and the use of selected seed have been recommended. There is no evidence of any deterioration of the plant, the best kinds of which yield excellent crops and excellent fibre, if the latter be properly extracted. The lower average quality of jute in recent years is ascribed to the bringing of inferior fibre to market to meet the enlarged demands, whereas formerly only the best jute found a sale. Middlemen are said to resort to fraudulent watering which gives a fictitious increase in weight, and, at the same time, induces heating and discoloration.

About one half of the jute crop is worked up in Indian mills, and a large portion of their production is used in the country, partly for export in the form of coverings for grain, seeds, cotton, &c. Indian jute bags are sent all over the world, but jute cloth goes mainly to the United States and Argentina. For the last two years cloth exports have been advancing to the detriment of sacking. More cloth is being shipped direct to Argentina, thus saving the extra cost of freight *viâ* Liverpool. The value of the jute manufactures exported in 1903-4 was £6,300,000. The growth in the export trade has been as follows:—

	1883-4.	1893-4.	1903-4.
Jute bags (No. in millions)	64	131	206
Jute cloth (million yards)	7	61	552

Jute coverings are mere coarse envelopes, dispensed with after use, and are used on account of their cheapness rather than any

intrinsic excellence. Their cost is rising with the rise in the cost of raw material, and a point may be reached where it would pay to use substitutes, at least in some markets. Hence proposals that have been made to impose an export duty on jute must be received with caution.

WOOLLEN MANUFACTURES.

The woollen mills during the last 10 years have increased their output from 1,953,000 to 2,977,000 lb., the number of spindles having grown in that period from 17,320 to 25,216, and the looms from 526 to 678. The production is not very great, nor can any important expansion be anticipated. The climate precludes any wide demand for woollens. Cotton goods are cheaper, and imported woollens are frequently preferred to home-made articles because taste or fashion or cheapness of production commend them to European and other consumers in India. The imports, which are most considerable in piece goods and shawls, comprise, besides the finer kinds of cloths, in which India cannot easily compete, various mixed and shoddy goods requiring elaborate machinery. These foreign woollens are largely sent by the Germans, who are said to be doing much business at a loss in order to capture the market. The shawls which they have been selling freely are of inferior size, weight, and quality.

The Indian woollen mills are six in number—one at Cawnpore, one at Dhariwal (Punjab), three in Bombay, and one at Bangalore. Only the first two are of any importance. They represent a capital of £213,000, or about 70 per cent. of the total capital invested in the industry, and they pay good dividends. They weave cloth for the army and police, and articles of superior quality generally, including broadcloth, tweeds, serges, shawls, flannels, hosiery, blankets, rugs, braid, &c., while the Bombay mills make blankets, socks, caps, &c. For higher-class woollens Australian wool is used, either pure or mixed with Indian wool, which is hard, dry, uneven, hairy, and short-stapled. There are many hand-loom factories for carpets, rugs, and blankets, the blankets being widely used, not only for bedding, but for protection against rain and cold in the open. The natives, however, often prefer stuffed cotton cloths as being warmer than woollens. The coarsely-woven and felted goods, widely produced at a very low price locally, are not likely to suffer from mill competition. The Punjab and Kashmir produce highly-finished goods made by hand, but the industry on a small scale tends to disappear. Change of fashion and European competition have reduced the demand for fine Indian shawls. The weaving of woollen pile carpets is widespread, but the inferior Indian wool will not take the finer shades of colour. The price of the carpets depends partly on quality and partly on the number of threads to the inch. The carpet factories of Amritsar are flourishing, and many weavers thrown out of the shawl industry have taken to carpet-weaving. There is a large and increasing production of carpets at Mirzapur, but the quality is said to have declined owing to a fall in the prices obtainable in England. The jail carpets of Agra are well known. The Madras carpet industry has fallen off in the centres of Ellore and Masulipatam. There are several carpet factories in Bombay city and around Ahmedabad. The exports of Indian carpets—the only woollen exports worth recording—are inelastic; they are bought chiefly by England and the United States. On the other hand, India has an import trade in carpets and rugs, mainly from England.

SILK MANUFACTURES.

Formerly Indian silks were famous in Europe, but, while other countries have improved their processes of production, Indian manufactures have suffered from defects in the methods of rearing, reeling, and weaving. Change of fashion, the use of cotton instead of silk goods, and, above all, the competition of France and Italy, China and Japan, have caused Indian silks to be supplanted even in India itself. Bengal still produces most raw silk, and has many silk filatures, but Bombay, which has the two most important steam silk mills, largely uses raw silk brought from China in the returning opium vessels. These factories send considerable quantities of silk goods, chiefly handkerchiefs and scarves, to Burma, which also buys silks from a mill near Calcutta. The Bombay mills supply a local demand of the middle and poorer classes for saris, &c. They make forward contracts for the supply of certain goods to large firms, who distribute them in India and Burma. The steam silk mills seem unlikely to extend appreciably so long as they weave cheap fabrics from waste silk, though they may cut out the hand-weavers in cheap saris and cholis. Scattered over India, but principally in Bengal, are about thirty hand-loom silk factories. Some of the Bengal factories use

wild silk (corah and tasar), and they are owned and managed by natives who employ no European machinery. In Bengal, promising experiments are in progress for improving silk rearing, and demands for raw silk are said to have increased owing to developments in the local industry. Silk weaving is also said to be progressing in Burma and the Punjab, the provinces that use most silk goods. At Amritsar pure and mixed silk goods are made with raw silk that comes from the Far East *viâ* Bombay. This imported silk is said to take colour better, and to be more easily worked than Indian silk. Silk goods are also produced by hand in the Central Provinces, United Provinces, and Bombay. The fine silk brocades of Surat and Ahmedabad are hand-made. Madras exports silk goods to countries whither emigrants have gone—Burma, the Straits, Mauritius, Natal, &c.

In the last few years an important development in silk production has taken place in Kashmir under State control. It now has ten first class filatures for reeling and storing cocoons. Silkworms' eggs are brought from Europe. Including rearers and operatives, there are 50,000 persons employed in this industry, which produces satisfactory silk and realises good profits. Experiments in weaving are in progress.

Indian exports of silk goods have declined, and are now only one-third of what they were ten years ago, while imports of silk goods have developed.

TANNING AND LEATHER MANUFACTURES.

The tanning and curing of raw hides and skins form an extensive industry, while leather manufactures are also of great importance. The census shows 9,000 workers in large tanneries and factories, 253,000 tanners, curriers, &c., 853,000 shoemakers, and 100,000 makers of water and other bags. For 30 years exports of hides and skins have expanded—the enormous supplies from Bengal and some other provinces being exported raw, while Madras draws supplies from all over India, and sends most of them abroad partially tanned or dressed to be retanned and curried in the country of destination. In 1903-4 Madras exported 90 per cent. of the tanned hides sent abroad, and 77 per cent. of the tanned skins. Owing to competition the prices of raw hides and skins have tended upwards for years to the great gain of India. The best raw materials are exported raw, but all rejections are tanned, so that the reputation of Madras tannages suffers. The collection of hides and skins and tanning work fall to the lowest classes, who require high wages to draw them from agricultural work. Any important reforms must involve the training of these labourers, but Mr. Chatterton—whose authority I am largely following in this section—says that some reforms have been effected, and sufficient skilled labour is probably forthcoming for more.

Indian hides are usually small and inferior owing to the poorness of the cattle, wear and tear of draft work, and injury by branding, which greatly reduces the value of the hides. Hides mostly come from animals that have died of disease, old age, or injury, and quality varies with seasons, being worst during famines, when supplies are most abundant. The local demand for hides in India is enormous. The skins, unlike the hides, are mostly those of slaughtered animals, especially goats and sheep, goat-skins being superior. They compare favourably with those from other parts of the world. Skins are chiefly tanned in Madras, the centre of the Indian tanning industry, and their price has risen in American and European markets. Most of the dried skins exported since 1899 have gone to America for the use of chrome tanners of glacé kid, and large quantities of pickled skins go to the same market. A bad defect of Madras tanning is the over-oiling of skins in order to get more profit. England buys nearly all the tanned skins. Madras slaughter-house skins, on account of careful tanning and excellent grain, take the first place in the London market, and are used for highly-finished bookbinding leathers. Madras tanning has developed, owing to the cheapness and good quality of the raw materials used in the tanning pits, and the tanner knows his business. Losses, however, have ruined many small tanneries, and large ones, properly managed, now do most of the work. Of late, Europeans, owing to speculation and keen competition, have tended to withdraw from the Madras skin business, which is now largely financed by wealthy natives. Hides are tanned but not curried, skins tanned but not dressed. India itself offers but a small market for high-class leather or dressed skins. Most of the lightly tanned hides exported are re-tanned for conversion into upper leathers. The hides being inferior can not be satisfactory even if tanned perfectly, and it is doubtful if Madras hide tanning can be improved considering the bad raw material,

though perhaps the up-country tannages can. The best Madras skins are good enough for all practical purposes, and probably no changes in tanning would yield better results. But the character of the work might be levelled up, and skins might be better graded. The industry requires more capital. Bombay and Cawnpore produce the best leather possible from the raw material available but the supply usually exceeds the demand, and the success of this industry is only assured by large Government orders. The chief tanneries in the United Provinces employ 4,915 persons, and the best leather they make would be hard to beat. In Bombay city there are eight to ten large tanneries, at Ahmedabad four large and many small ones, at Surat two large ones, and at Belgaum one large tannery, which exports to London. In Calcutta there are seventeen tanneries (seven of them owned by Europeans). The local native tanner is losing his occupation through the competition of these large up-to-date tanneries, and through the high prices of raw hides and skins.

Cawnpore has been a centre of leather manufactures for more than a century. For 35 years Government has had a harness factory there, and the Army Boot and Equipment Factory of Messrs. Cooper, Allen and Co. supplies boots to the British army in India, to most of the native troops, volunteers, and to Government departments. Their factory employs 3,685 persons. This city stands first in boots, shoes, harness, saddlery, trunks, and other leather goods in European style, and articles supplied to troops in the South African war were highly commended by Lord Roberts. The village saddlers and shoemakers in the United Provinces get better and cheaper leather from the large tanneries than they could get from the native tanner, and they have not suffered from foreign competition. In Bombay city many articles of good workmanship are produced. The Western India Army Boot and Equipment Factory executes large Government contracts, while other factories do work for the police and railway servants. These factories turn out goods of a kind formerly imported, and they appear to be capable of production for export. Sholapur produces bags, trunks, &c. Most footwear is made in the bazaars, and shoes of European pattern are increasingly worn. The local leather worker holds his own in spite of the competition of shoes from the great leather manufacturing centres. In Bengal foreign leather is much used by town shoemakers, and the inferior indigenous leather manufactures are being replaced by cheaper and better imported goods, except as regards water bags and other rough articles. In Madras presidency the only large factory is the Government harness and saddlery workshop, which also produces equipment, accoutrements, &c., for troops, the leather being brought from Sion (Bombay). There is a boot and shoe factory at Coimbatore, but most shoes and sandals are cheap and inferior articles produced by native shoemakers in their homes. The largest consumption of leather in Madras is for bags for raising water from wells, and for oil and *ghi* pots. About a million water bags are required annually in Madras; they cost from six to nine rupees each and last barely a year. The Madras School of Art is producing these bags by the chrome tanning process, which requires some scientific knowledge and skill in manipulation. Chrome tanned leather is superior to vegetable tanned leather in many respects. It is soft, pliable, and impervious to damp. Once dried the leather can only with difficulty be wetted again, hence the finishing process must take place immediately after tanning. Hitherto ordinary tanners have only produced half-finished goods for export, and it is useless to introduce chrome tanning unless at the same time skins are made into marketable articles. The general opinion in Madras is that finished goods cannot be produced well and cheaply enough to be exported at a profit. Attempts to make chrome tanning on a commercial scale pay in Bombay and Madras do not appear to have succeeded. For success large capital and extensive plant are needed as well as intelligent labour. Mr. Chatterton thinks the first object should be to improve the supply of leather for local consumption, especially water buckets. The non-absorbent chrome-tanned leather is useful for these, for it becomes more flexible the more it is wetted. These buckets, though more expensive than existing ones, are twice or thrice as durable. Hence their use would involve an economy in the use of hides and more hides could be exported.

Taking India generally the native leather industry tends to decline with the larger exportation of raw material and the increased importation of leather goods—the extent of which shows the opening for local manufactures.

The Dyeing Industry.

After textiles and leather, in which dyeing is important, it is necessary to say a few words about this industry, which for centuries has employed a large number of hand-workers using indigenous dyes. The last census showed that there are 113,000 dyers of textiles and 81,000 leather dyers. In this, as in allied industries, a revolution has occurred. In the first place, special dyeing factories, equipped with steam machinery, have been established in the great textile centres, Bombay (which has three large works) and Ahmedabad, while up-to-date dyeworks have been added to cotton, woollen, and silk factories in the chief manufacturing cities. In the second place, imported aniline and alizarine dyes are superseding indigo and other long famous Indian vegetable dyes. Most Indian dyes are fleeting as well as expensive and troublesome to work, while the mineral dyes are cheap and easy to manipulate. As a consequence, imports of the latter have increased five-fold in 25 years, and they are increasingly used throughout India to the detriment of the small local dyers and of the producers of vegetable dyes, whose products are being ousted from both home and foreign markets. The two great German firms that deal in artificial dyes give free tuition in the use of their colours. Whether the cheaper and more brilliant tints are more attractive is a matter of taste, but they have undoubtedly captured the Indian market.

Indigo.

The only Indian dye-stuff that appears to involve the use of machinery for production on a considerable scale is indigo. This important article of trade, long a source of profit to European planters, has fallen on evil days owing to the encroachments of a mineral dye, synthetic indigo, chemically produced in Germany. Opinions are still divided as the relative merits of the natural and artificial dyes, and the former has not ceased to be used, though its competitor is increasingly consumed in Europe and America, in Egypt and Japan, which once bought large quantities of Indian indigo. Owing to the unfavourable prospects of the vegetable dye, the acreage planted with indigo in India has been steadily curtailed for some years, and last season, when the weather was bad, the area fell to 473,700 acres, as against 706,600 in 1900, and an average of 1,184,000 acres in the 10 years ended 1902. Hence the number of factories has fallen to 553, which afforded seasonal employment to 81,750 persons in 1903-4 in Bengal, Madras, and the United Provinces. The work is not highly specialised, and many of the small factories are owned and worked by natives. The German dye firms are said to have combined to raise the price of their synthetic indigo, which is believed by some to be produced at a loss, inasmuch as the processes of production are numerous and costly and there is no bye-product. In any case this increased price should benefit the Indian dye, the selling price of which has fallen heavily. Although experts are endeavouring to improve the cultivation and manufacture of indigo, the decline in the indigo acreage appears to imply that the planters expect very little result from these experiments.

Paper Mills.

Paper-making on European lines seems at first sight to offer great scope, but little progress has been made. There are nine mills—four in Bengal, four in Bombay, and one in Lucknow—with a total capital of about £450,000. Two have paid no dividends for some years, and two have done fairly well. During the last ten years production has increased from 29 to 43 million pounds. Most of the foolscap and much of the note-paper, envelopes, and blotting-paper used in the Government offices are now bought from the mills. The existing depression in the trade is attributed to large imports of cheap wood-pulp paper, which, if less durable, is more attractive in appearance than the Indian paper made from grass, jute cloth, &c. The chemicals required have to be imported, and they are expensive. Meanwhile imports of paper and pasteboard are increasing. The Forest Department is now inquiring as to the possibilities of supplying wood-pulp for paper-making.

Iron and Steel Manufactures.

A separate heading is assigned to this subject more owing to its intrinsic importance than because iron and steel manufactures have attained any notable development. The only iron-smelting by European methods is in Bengal, and the only works fully equipped for iron and steel production are those of the Bengal Iron and Steel Company at Barakur. There has been a general decline in the native charcoal iron industry within range of the railways, which distribute the cheap imported iron and steel, but in remoter districts the old industry survives, and in parts of the Central

Provinces has even improved, though the production is under 5,000 tons of iron and a little steel. In the Sambalpur district over 200 small direct process furnaces are still at work. Ore is produced in considerable quantity only for the company above mentioned, and in small quantities for the numerous native foundries in Central and Southern India and the East Indian Railway workshops at Jamalpur; but the annual average production of iron ore in Bengal for the six years ended 1903 was only 57,678 tons, valued at £8,338. It is regrettable that, owing to the non-existence of a steel-making centre in India, the rich deposits of manganese ore in Southern India are being exploited for export. If steel were made, a demand would arise for ferro-manganese, and the lower-grade ores, now neglected because they do not pay to export, would be developed.

Although India has room for a considerable iron manufacture leading up to the manufacture of machinery, there is, as just remarked, but one important ironworks. In the railway workshops, however, and in some large foundries in Calcutta and elsewhere, valuable work is done.

The Bengal Iron and Steel Company, during the year ended 30th September, 1904, produced 37,883 tons of pig-iron, and 13,958 tons of castings, *i.e.*, sleepers, chairs, pipes, columns, &c., mainly for irrigation works and water-works. The Company, which receives special encouragement from Government, has a complete plant for turning out 25,000 tons of steel per annum in the form of rails, joists, tees, angles, &c., and steel-making began in November, 1904. The steel is made by the basic open-hearth process, and is said to be fully equal to European and American steel. This is the first steel plant erected in India for steel production on a commercial scale from indigenous raw material. The blast furnace plant is now being enlarged so as to increase the pig-iron output by about 500 tons a week. The company's customers are chiefly the railway companies (especially the East Indian), but considerable quantities of pig-iron are sold to private foundries for conversion into castings. The iron and steel produced should be able to compete increasingly with the German and Belgian iron and steel out of which household articles are largely made in the bazaars. A small quantity of pig-iron is exported to Singapore, Colombo, &c., but local Indian demands absorb most of the production.

The railway engineering workshops are mainly engaged in the work of erection and repair—carriage and waggon under-frames and other metal-work being largely made from imported iron and steel. The East Indian Railway Company made a complete State train of eight bogie carriages at Lillooah in 1903, while at their Jamalpur works, which employ 10,000 men, locomotives can be almost completely built. The output at these works has enormously increased, and the Company aim at making all the metal work they require by means of their iron and steel foundries and rolling mills. The works are fitted with electric driving plant. Throughout the country great developments are taking place in railway workshops, and there seems no reason why India should not soon produce her railway material as well as war material.

The large private ironworks at Howrah and Kendua (Burdwan) employed 4,550 and 3,100 hands respectively in 1903. Besides these there are numerous iron and brass foundries scattered over India, though mostly in Bengal. England furnishes the bulk of the varied kinds of machinery required for India's nascent manufactures—cotton, jute, silk, wool, matches, screws, candles, soap, paper, brass, iron, flour, rice, &c.—and will probably long continue to do so, owing to her exceptional powers of producing complicated machinery. An Indian firm, however, is said to be supplying spare parts for cotton machinery.

Recently rich and abundant iron ore deposits have been found in the Central Provinces, and proposals are said to be under consideration to manufacture coke for blast furnaces, to preserve the bye-products—tar and ammonium sulphate (used as manure)—and to erect a sulphuric acid factory. If expectations are realised, an active development in iron and steel making is assured.

SUGAR MANUFACTURE.

The manufacture of sugar is an ancient Indian industry. At one time the East India Company exported large quantities from Bengal to England, but this trade was practically killed by a system of preferential trade designed to benefit the ever-importunate West Indian planters. Subsequently the growth of large refineries in Great Britain led to a renewed demand for Indian sugar, and a trade in unrefined sugar began from Madras, and has since continued, though it has dwindled to small dimensions. Lastly, there arose in India a sugar industry on modern methods and supported by European capital. The

output of these few refineries, and of a vast number of small native factories, has for a long time failed to meet the demands of a population who mostly use sugar as a daily food. Everywhere in India sweetmeats may be seen on sale, and they are bought by the poorest. An enormous expansion in the sugar industry, therefore, seems possible. At first the Indian deficiency in sugar was made up by Mauritius. For the last ten years large quantities of beet sugar have also been imported, while for two years past Java has sent large and increasing quantities of unrefined sugar. The abolition of the bounty system has not appreciably checked the beet sugar imports, and the total sugar imports into India for the last three years have beaten all records. It is clear from these facts that India, which is capable of producing enormous quantities of cane sugar, may profitably extend its cultivation. There are probably 3,000,000 acres under sugar, about two-thirds of the area being in the United Provinces and Bengal. Both are protected from foreign sugar by the long sea-voyage, and to a large extent also by long land transport. Instead of an increase in the sugar area in recent years, there has been a decline, ascribed to the preference given to grain and cotton crops. But in 1903-4 the acreage and yield were greater than in the previous year. For a considerable time the price of raw sugar (*gur*) has been very high, because of the urgent up-country demand for such sugar, which is little affected by foreign competition. This explains the large imports of Java sugar for refining. The chief requisite for an enlarged output is an improvement in the processes of cultivation and manufacture. Cultivation is unscientific, the methods of extracting the juice are defective, and there is great waste in refining, while the product is coarse. Hence the yield of cane per acre is small, and so is the yield of saccharine matter. Some native producers still use antiquated wooden mills, though the great majority have adopted the more expeditious and effective iron presses, which can be hired by the day in Bengal. Many difficulties have to be surmounted before India can oust foreign supplies and produce all her own sugar. The large demand for unrefined sugar, by keeping up its price, raises the cost of refining sugar, and so gives an opening for foreign refined sugars. These sugars are preferred by natives owing to their whiteness, which is due to the use of bones; but owing to caste prejudices bones cannot be used in the manufacture of sugar in India. The first requisite for progress is a much greater number of large central refineries worked by steam-power similar to those established at Cawnpore, Cossipore, and elsewhere. The manufacture is not complicated, and it requires no large proportion of skilled workers. One great difficulty is to obtain adequate supplies of raw sugar from the natives, who only cultivate on a small scale. A large refinery requires abundant and assured supplies of cane cultivated by the best scientific methods. Throughout the vast area of Northern India from the Punjab to Bengal a vast field is offered for sugar refineries on modern lines, and many of those at work already appear to be reaping good profits.

Tea Production.

Of the industries mainly agricultural, though partly manufacturing, the chief is tea, which is a manufacture to the extent of about one-third of its selling value. Since the industry began its expansion has been enormous. The establishment of large plantations and the use of machinery has cheapened production, while freedom from the adulteration and impurity that characterise the hand-made China tea has given it a preference over the latter. The large capital employed in the tea industry is nearly all British, and the labourers have been drawn, at great trouble and cost, from the congested tracts of India. Tea is the one industry of Assam, which, without it, would not have been developed. In recent years tea has passed through great vicissitudes. A too rapid extension of the area under cultivation caused over-production, and prices fell heavily. When the planters had taken active steps to remedy this evil by curtailing the acreage, by finer plucking, and by extending the sale in India and abroad, the English tea duty was raised from 4d. to 6d. a pound as a war tax. When the war was over the duty was raised to 8d. a pound, and though this addition has happily been removed, partly as the result of appeals made by the Viceroy, the increment assigned to war purposes still remains. The tax of course does not fall directly on the planters, but indirectly it operates against them by checking consumption, and by forcing them to keep down prices unduly in order to prevent a still greater fall in consumption. Thus, an article of prime necessity in the domestic economy of this country, an article produced almost wholly within the Empire, an article on which the incidence of taxation had much increased,

even with the fourpenny duty, owing to the fall in prices, is still exposed to a duty of nearly 100 per cent. *ad valorem* on the average price of tea, while the incidence on the cheaper kinds consumed by the most necessitous classes is much more severe. High duties have led to a resumption of coarser plucking, and have given an impetus to the importation of inferior non-British teas in order that the price of cheap blends may be kept down. Rubbishy teas which the United States, Canada, and Australia refuse to admit have been dumped down in this country. In all these Anglo-Saxon countries tea is admitted free of duty, while in the following countries, which are more or less Teutonic in origin, the duties per lb. are lower than ours:—Germany, 5½d., Denmark, 4d., Sweden, 3d., Holland, 2½d., Switzerland, 1⅔d. The consumption of tea in England has fallen from 6·16 lb. per head in 1901 to 6·01 in 1904, and clearly a heavier tax must raise prices and check consumption. Outside this country tea is making headway, and Calcutta is becoming to an increasing extent a great distributing centre for foreign markets.

Tobacco Manufacture.

The area under tobacco in India is practically stationary. Bengal, containing about half the acreage, manufactures little, but exports crudely cured raw material to foreign countries or to Burma for cigar-making. The well-known Indian cigars come mainly from Madras, which contains only about 15 per cent. of the tobacco acreage. A leading Madras firm that I consulted ascribed the non-expansion of the export trade to the unscientific cultivation and curing adopted in India as compared with America, the Dutch East Indies, &c., where the production is in European hands. The Madras leaf is too coarse, and is not suited for pipes and cigarettes, while for cigars, imported leaf from Sumatra is used as an outer wrapper. India itself offers only a small market for its own cigars, but their cheapness has led to a considerable demand abroad. An extensive foreign trade, however, cannot grow up until there is a large and regular supply of improved leaf of standard quality. The export of Madras cigars has recently declined, owing, it is said, to the diminished supplies required in South Africa since the war, but the export of Burma cigars has increased. Imports of cigarettes have greatly developed in the last four or five years, and natives of all ages and conditions may be seen smoking them throughout India. It is unfortunate that this extensive and growing market is not exploited by Indian planters. Several provincial governments are experimenting in tobacco, and the recent agricultural conference at Pusa recommended the appointment of a tobacco expert and chemist. India possesses soil and climate well suited for tobacco, but the industry requires European supervision, adequate capital for production on a large scale, and a supply of native skilled labour.

Lac Factories.

Many factories exist in Bengal and the United Provinces for the manufacture of lac, 45 out of a total of 93 being at Mirzapur. Lac is an incrustation produced by certain insects on the twigs of trees. The twigs are broken off and collected by jungle tribes, and out of the stick lac is made seed lac, from which the shell and button lac of commerce is manufactured. Steam-power is used in some factories, but handwork holds its own. The last Bengal administration report (1903-4) stated that in the Burdwan Division lac manufacture was declining through the competition of cheap foreign lac made by a chemical process. This competition, however, can hardly be serious as yet, for of late years the price has enormously risen owing to a sudden and apparently inexhaustible demand for lac, which is largely purchased for electrical purposes in England, America, and Germany. In spite of an extraordinary rise in prices and abundant supplies, consumption has increased. Unfortunately the large demand has led to adulteration with rosin.

Petroleum Production.

The increasing output of petroleum and its various products in Burma and Assam is very encouraging. Burma produced 85 million gallons in 1903, a growth of 55 per cent. in a single year, while the Assam output is increasing. The consequence has been a considerable decrease in imports of foreign oils. The Burma Oil Company refines the crude oil and manufactures gas oil, batching and lubricating oils, paraffin wax, and candles. This Company is enlarging its up-to-date refining plant, constructing a pipe-line to Rangoon, increasing its fleet of tank-steamers, and the number of its storage tanks for the distribution of oil in the chief Indian cities. In Calcutta candles are being made from wax imported from Burma. Owing to the production of

paraffin wax candles, a considerable export trade is springing up, while candle imports have diminished. India candle exports rose from £3,304 to £60,368 between 1901-2 and 1903-4, Australia, New Zealand, the Straits, and China being the chief purchasers. Government has prevented the intrusion of Trust Corporations of the international type into the Indian oil fields which, in 1903-4, yielded a royalty of £80,000 to the State. There is every prospect of a wide extension in the outturn of cheap mineral oil and its products.

FLOUR AND OIL MILLS.

These mills are taken together, because flour is not infrequently ground in the oil-mills. But so considerable has been the progress in flour-milling and oil-milling, and so great are their potentialities, that they may be expected to develop independently on a large scale. Flour-mills are general, especially in Bombay, the Punjab, and Bengal. The mills at the great wheat port of Karachi are flourishing, and developments are taking place. Large mills exist at Howrah, and new mills are being erected at Lahore, Umballa, and Allahabad. Besides the home trade, there is an export trade in flour, amounting in 1903-4 to over 40,000 tons. Of this five-sixths went from Bombay, chiefly to countries in the Indian Ocean. There seems no reason why this increasing trade should not find an outlet in Europe, and why England should not buy flour from India as well as from North America. Frequent complaints are made of the dirty character of the Indian wheat sent to this country, and it is estimated that from 5 to 10 per cent. of last season's imports consisted of clay and other impurities. If the wheat were milled before shipment freight would not have to be paid on thousands of tons of dirt, and more employment would be found for native labour.

With regard to oil it has often been suggested that the oilseeds now exported in vast quantities to Marseilles, Hamburg, Hull, and other European ports should be crushed in India, and the resultant oil either exported or manufactured into soap and other products. One great obstacle at present is the absence of a demand in India for the important bye-product, oil-cake, which finds a ready and profitable sale in Europe, whereas India uses little, and even exports much of what is already available. Oil-pressing is an ancient Indian industry, and though, for lighting purposes, kerosine is driving out vegetable oils, they are still widely obtained for other purposes from small mills, especially in Bengal and Madras. Thus the suburbs of Calcutta teem with castor-oil mills. The export of Indian oils is considerable and increasing. Cocoanut-oil, which has been largely imported, is now being largely exported from Madras. The total vegetable oil exports were £556,000 in 1903-4, as against £354,000 in 1901-2. Large capital is needed for economic production on a large scale, by which alone cheapness and uniformity of quality can be secured.

MINOR MANUFACTURES.

A considerable number of minor manufactures can be only adverted to briefly.

(1) *Manufactures proper.*—There are 27 breweries in India, which produce annually about 6,000,000 gallons, two-thirds of this quantity being brewed in the Punjab and the United Provinces. About one half of the output is bought by the Commissariat Department, while the remainder is sold to the civil and military population, chiefly Europeans in the hill stations. There are ten small distilleries, while some breweries and sugar factories distil rum. Coir manufactures are progressing as the increasing exports show. One coir matting factory in Travancore employs over 1,100 hands. Rope works are numerous and increasing; some near Calcutta are owned by Europeans, and there are many small native works, chiefly in Bengal and Madras. The Ghoosery works employ about 440 hands. Umbrellas are being locally produced from imported cloth and fittings. In Bengal, the Punjab, and the United Provinces are several large soap factories, which turn out very fair toilet soaps by European processes, while a great number of small native works in Bengal and elsewhere make crude soaps used by washermen and dyers. India now has many aërated water factories and numerous ice factories, though only a few produce on a considerable scale. Owing to their cheapness, ice and mineral waters are largely consumed by the natives in all parts. The manufacture of matches is of slight extent, though there is a great demand for consumption, as the large imports from Japan and Europe prove; but it is said that production is handicapped by the dearness of chemicals and lack of the proper kind of

wood. Among miscellaneous factories are a few small chemical works, gasworks, a mill for extracting and preparing agave fibre (Coorla, Bombay), perfumery factories (at Jaunpur and Ghazipur), brush factories, tent factories, &c. There is a large and increasing number of printing presses, which points to a wider diffusion of education. At the recent Bombay Industrial Exhibition were represented many nascent manufactures, including safes, locks, paints, &c. Art industries may be mentioned only to be dismissed from consideration. Though their production is widespread, and employs in the aggregate a large number of craftsmen who work by hand, their commercial importance, if we except carpets, already dealt with, is not great. There is, however, some export of shawls, jewellery and plate, brassware, ivory manufactures, wood manufactures, &c.

2. *Industries connected with Agricultural, Animal, and Forest Produce.*—Rice mills claim the first notice here. In 1903 they numbered 112, and employed 16,000 persons. This growing industry is important only in Burma, where large capital has been sunk in mills at the seaports. Practically, all the rice now exported is husked before shipment, employment thus being found for country labour, chiefly imported from India. The husks are used as fuel. Coffee works exist in the Madras Presidency to the number of 18. In recent years the coffee industry has greatly suffered from leaf disease and from Brazilian competition, resulting in a decline in prices. There are several bone-crushing mills at Karachi and elsewhere, bones being crushed for export to the extent of about 10,000 tons a year. Saw mills, like rice mills, are to be found chiefly in Burma, where the teak industry is important at Rangoon and Moulmein. Of 90 saw mills in India, 72 are in Burma and 11 in Assam. Much timber is used for tea and opium chests, for railway sleepers, carriages, trucks, &c. But the imports of manufactures of wood exceed the exports, which shows that there is scope for enlarging the output.

3. *Manufactures dependent on Mineral Products.*—Considering its great size India is not rich in mineral resources, and few of the minerals exploited are worked with scientific appliances. We have already dealt with iron and steel manufacture. An aluminium factory, owing its origin to the Madras School of Arts, exists in that city. It is now worked by a company, and the industry is said to be making steady progress. Considerable sales of sheet metal are made to native workers, who manufacture utensils from it in the bazaars. It is lighter than copper, which it is superseding. In a recent report on Indian mineral production, Mr. Holland has pointed out that India has a possible asset of great value in the deposits of laterite, which cover wide areas. It has lately been found that many of the deposits contain large quantities of alumina, which might be extracted on the spot, either for export as such, or for the manufacture of aluminium in the country. To prepare the alumina, however, would require caustic soda, not at present made in India. But its production is possible by the separation of chlorine, from which bleaching powder is prepared, by the electrolytic decomposition of dilute brine, and as caustic soda and bleaching powder are now largely imported for paper-making, there would be a market for both, apart from the requirements of alumina manufacture. Salt refineries exist here and there, and a large quantity of salt is evaporated from sea-water. Saltpetre refineries on a small scale are worked by natives in Calcutta and other parts of Northern India. A new industry is said to have been set on foot in Calcutta for making tea-lead out of raw material brought from Australia, the machinery having a productive capacity of 10,000 tons per annum.

Common clays are used everywhere for making bricks, tiles, and the cheaper kinds of pottery, while finer varieties are used for glazed pottery. There are two large potteries belonging to a Calcutta firm, one at Raniganj employing 1,050 persons, and one at Jubbulpore employing 584. They produce piping, tiles, and other large articles in considerable quantity. There are many small brick and tile works, chiefly in Bengal and Madras. India has two considerable cement works, one in Bengal and the other in Madras. The progress made in works for producing building materials is important, as large quantities of bricks, tiles, cement, piping, &c., are imported. India possesses plenty of ornamental building stone, but owing to lack of enterprise in placing it on the market in forms suited to the immediate requirements of builders, it is little used in the chief cities, its place being taken by Italian marble and Aberdeen granite. An important recent development has occurred in quarrying the limestones of the Khasia and Jaintia hills, partly for use in the manufacture of lime and partly for the manufacture of cement near

Calcutta. Limestone is also quarried near Katni, and most of it is carried a distance of 530 miles by rail to the Barakur ironworks for use in blast furnaces. The manufacture of mineral paints is small compared to the demand and to the natural resources in suitable minerals. Steatite, which is widely distributed, is used for making pots, dishes, &c. An inferior kind of glass, used for bangles, is made in various places from the common impure river sands and efflorescent alkali salt found in many parts of India, but attempts to make better glass on a large scale have hitherto failed, the chief difficulty being want of quartz sand of the requisite purity and of suitable quality. Mr. Holland, in the report already mentioned, refers to the fact that India has no deposits of free sulphur worth working, and makes some suggestive remarks, which I condense, on the value of sulphur and its products. He points out that there are considerable imports of sulphur and sulphuric acid, and that a cheap and abundant supply of the acid would be the key to many industries now enfeebled or non-existent, and would produce an economic revival. Thus, with cheap sulphuric acid, several chemicals for paper-making could be produced in India. If the by-products of coke-making were turned to account, there would be needed a supply of this acid, which is essential to most chemical and many metallurgical industries. It is a necessary link in the chain of operations involved in the manufacture of alkalies, with which are bound up the manufactures of soap, glass, paper, oils, dyes, and colouring matters, while as a by-product it permits the remunerative smelting of ores which could not otherwise be developed. The revolution in European chemical industries consequent on the cheapening of sulphuric acid, has nearly exterminated the manufacture in India of alum, copperas, blue vitriol, and the alkalies, has reduced the saltpetre exports, is robbing India annually of 100,000 tons of phosphatic fertilisers in the form of bones, and forces her to pay £10,000,000 a year for European products obtained from minerals identical with those lying idle in India. But though sulphuric acid and the alkalies are essential to so many industries, they can only be manufactured profitably when a country offers a market for the by-products. These conditions are rapidly ripening in India, and enterprising capitalists should remember that her present requirements are but a fraction of the consumption that will follow any material reduction in prices through local production.

Possibilities of Industrial Development.

In recent years much has been said by both Europeans and by Indians about industrial development, but though such discussion is not useless, development has so far been mainly on paper, and the oft-predicted outburst of industrial activity has not arrived. It may be inferred from the facts I have set forth, that though some progress has been made in certain fields, the total achievement has been small. When a country with 300 million people has only two advanced manufacturing industries employing more than 20,000 hands, when it has only one fairly large iron and steel works, and when coal production has stopped at about eight million tons because demand is slack, can we say that industry has attained any important development? Even the cotton and jute goods now forming the chief manufactures are mostly of the simplest and coarsest kinds, while silk, woollen, and leather manufactures have, except in a few centres, attained little development. Several industries merely carry raw products one stage towards their final form. The total population engaged in modern manufactures proper hardly exceeds a million, in other words, it is less than the annual increment of population in a normal year, free from famine or epidemics. Again, progress seems likely for some time to diminish rather than increase the artisan population by facilitating the competition of articles produced by modern methods with the cruder productions of the native artisans, who are thus driven into agriculture. The very industrial progress that has been commended as securing diversification of labour appears for the present to be tending in the opposite direction, and not towards the relief of pressure on the soil. If, however, we look beyond manufactures and take a broader survey, we find that modern conditions have opened up wide fields of employment for natives in railways, mines, irrigation works, the police, &c., and so made the supply of labour short of the demand in manufacturing industries.

India, in fact, must move slowly. The European capital and enterprise available are limited, and those who are unfamiliar with the conditions of Indian life and the customs and methods of the people must tread warily. The wealthier natives often lack the enterprise, education, scientific and technical knowledge, taste, and aptitude indispensable for industrial pursuits. Not until the

population is much better educated will their wants be greatly multiplied, and not until agriculture is far more developed can this enlarged range of wants lead to an effective demand for a variety of manufactured articles. The circumstances, then, of production and consumption alike preclude any rapid industrial development.

Meanwhile the possibilities of progress seem to lie in those simpler manufacturing industries that can give employment to large numbers of the population, and require only a minimum of skilled labour. The improvements that seem possible in the ancient handicrafts are desirable more perhaps for social than for economic reasons. But industrial development proper must lie in the substitution of locally manufactured goods for those largely imported, or in the manufacture of produce now exported raw. For a long time the latter must probably be the most fruitful sphere of effort.

In Appendix IV. will be found a list of the chief kinds of raw produce now exported. As half the cotton and jute are exported raw, there is clearly room for expansion in the manufacture of these, and it is gradually proceeding. Wheat can be much more profitably exported as flour, and an extension of oil-pressing by steam mills may be profitable if oil-cake can be utilised. Silk, wool, hemp, and various other fibres—especially that of the ubiquitous aloe—seem to offer scope for more extensive manufacture. For the present it is doubtful whether hides and skins, which fetch very high prices when exported raw, tanned, or dressed, can be profitably turned into leather and leather manufactures on a large scale, though gradual progress appears possible. A difficulty that must occur is whether India can as readily find a market for her manufactures as for her raw materials. But though she has no monopoly of wheat, oil-seeds, hides and skins, &c., her contributions to the world's markets are so considerable, that if any shortage occurred in her supply of raw materials due to their conversion into flour, oils, leather, &c., a demand would almost necessarily arise for the latter.

With regard to the substitution of locally manufactured goods, we have seen that India already produces more or less in the way of cotton, woollen, and silk goods, iron and steel, soap, candles, boots and shoes, harness and saddlery, sugar, matches, tobacco, bricks, tiles, cement, &c. She has produced with growing success cotton yarn and piece goods, because for these she has both a home and a foreign market. But in most of the articles enumerated the Indian products are inferior in quality, and a long time must elapse before India has the capital, enterprise, machinery, and skill to produce them. It is, for the present, more beneficial economically that she should import them, because it is more profitable to exchange her abundant agricultural wealth for articles in which her productive power is inferior. Even England cannot effectively compete with foreign countries in some of these commodities, *e.g.*, mineral dyes, glass, paper, &c. The cheapness of many of them lies in the fact that they are produced on a large scale for the world market by the most modern methods, and the cost of production would be relatively high if India merely tried to satisfy the demands of her own market. If we look down the list of manufactures in Appendix V., we shall see how large are most of the imports compared to the exports of such articles, and yet how small are the former considering the size of the population. Not only is India's capacity slight for producing sufficiently high qualities of these goods, but the question of taste has to be considered. In glassware, dress, millinery, footwear, &c., an enormous degree of variety is possible, and it is better to choose from all the products of Europe and America. India probably gets her imported manufactures more cheaply owing to favourable freight rates. Such goods occupy but little space, and the larger proportion of the freight charge for the round trip is paid for the bulkier raw produce that constitutes the return cargo. On the other hand, as pointed out in the closely-reasoned Indian Blue-book on Preferential Tariffs, raw produce so predominates in homeward cargoes that fancy freight rates are often charged for small consignments of manufactured goods, such as oil in casks, to the prejudice of Indian industry. The cheapness of outward freights has no doubt aided the sale of Continental manufactures—as Western Europe buys large quantities of raw produce from India. Their sale has been still further aided by legislation, which was designed to protect British goods, but has had a precisely contrary effect. At the recent Conference of Chambers of Commerce in Calcutta, a resolution was unanimously passed condemning the clause in the Merchandise Marks Act requiring all foreign goods to be marked with the country of origin, on the ground that it had tended to divert trade from

local British merchants to foreign agents located in India. Natives find it cheaper to deal direct with these agents than to buy foreign goods through English firms. The Act has secured a splendid advertisement for foreign goods, and one purchase has led to another, to the detriment of British merchants and ship-owners. The fact that the poverty of the natives forces them to study price before quality has given a still further advantage to Continental goods.

Government and Industry.

The Government of India has always recognised that it must render direct aid to industry, and never has this recognition been so marked as during Lord Curzon's viceroyalty. The central and local governments are spending large sums in research, undertaken in order to improve the staple crops that furnish raw material for manufactures—jute, cotton, silk, indigo, sugar, tobacco, &c. The establishment of the Pusa Research Institute, and the recent budget grant for agricultural experiment, research, demonstration, and instruction, all point to the Government's desire to improve India's premier industry on which all other industries turn. The essential work of primary, technical, and industrial education, in which India has much leeway to make up, has been taken in hand. Further, in pursuance of the aim to develop those Indian industries which seem most likely to attract native capital, scholarships are being granted to selected students to enable them to obtain instruction in Europe and America. Fully-equipped trade schools are to be established in the larger industrial centres where the need of trained artisans is felt by employers. Meanwhile, much valuable instruction is being given in railway workshops, mills, mines, &c., under European supervision. In these the natives acquire skill and knowledge and habits of order. Government has cordially co-operated in the late Mr. Tata's scheme for an Institute of Research. It may be hoped that similar schemes will be formulated for, and carried out in, the chief industrial cities, and especially that fully equipped laboratories will be established with highly-qualified chemists. In India, as in England, there has always been a neglect of science. More, however, has been done in the last few years than ever before in the appointment of scientific experts, and a Board of Scientific Advice has recently been constituted.

It is often said that Government should encourage Indian industries by purchasing more of its stores in the country. But there is a standing order that stores, if suitable in quality and price, shall by preference be purchased in India, and, to give specific instances, this is now done in the case of malt liquors and army boots, once bought in England. Most, however, of the stores now purchased for the army and the railways, as also stamps, scientific instruments, &c., could not be economically obtained in India. An important step recently taken is the erection of more Government factories for arms, ammunition, rifles, gun-carriages, cordite, &c., in order to render India independent of external supplies of war material, for which there are already eleven factories. The State also has factories for opium, quinine, turpentine, &c. State engineering workshops exist in connection with railways and irrigation works, while in the jails carpet-weaving, blanket-making, oil-pressing, &c., are undertaken. By extending railways Government has supplied certain conditions of successful manufacture—cheap transport for raw material and fuel, and also for the distribution of finished goods. Government in December last extended its support to the Bombay Industrial Exhibition, which was organised by Indians. Lastly, Government has instituted a Ministry of Commerce and Industry in order to concentrate the various official activities bearing on trade and manufactures.

In conclusion, I must return my thanks to a large number of officials and non-officials, European and native, in India and in England —too numerous to specify by name—who have helped me with information and suggestions, as well as to various writers, notably Sir George Watt and Mr. O'Conor, from whose works I have borrowed hints for this paper, which would otherwise have been far more incomplete.

APPENDIX I.—Manufacturing Industries by Provinces.

Every province has mills for ginning, cleaning, pressing, spinning, and weaving cotton, and every province also has printing presses. These are consequently omitted in the following list:—

1. *Bengal.*—Jute mills and presses, flour mills, oil mills, tea-gardens, indigo factories, lac factories, paper mills, silk filatures and mills, iron, steel, and brass foundries, engineering works, soap factories, saltpetre refineries, bone-crushing mills, brick and tile factories, cement works, sugar factories, ice factories,

mineral water factories, potteries, rope-works, chemical works, electrical works, gas-works, &c.

2. *Bombay*.—Dye-works, flour mills, bone-crushing mills, cement works, brick kilns, electrical works, gas-works, workshops for railway and tram plant, iron and brass foundries, silk mills, oil mills, woollen mills, tanneries, harness factories, boot factories, paper mills, breweries, distilleries, carpet factories, match factories, &c.

3. *Madras*.—Tobacco factories, coffee works, fish-curing yards, indigo factories, aluminium factory, foundries, coir factories, cement works, oil mills, rice mills, sugar factories, rope-works, tanneries, leather factories, tile factories, breweries, &c.

4. *United Provinces*.—Tanneries, boot and shoe factories, harness and saddlery factories, woollen mills, flour mills, oil mills, indigo factories, lac factories, sugar factories, paper mills, foundries, breweries, &c.

5. *Punjab*.—Flour mills, woollen mills, oil mills, carpet factories, sugar factories, tile works, breweries, &c.

6. *Central Provinces*.—Potteries and breweries.

7. *Assam*.—Tea-gardens and saw mills.

8. *Burma*.—Rice mills, saw mills, petroleum refineries, and foundries.

N.B.—In some cases the industries are not wholly carried on by mechanical power.

APPENDIX II.—The Principal Manufacturing Industries, with the numbers employed according to the Financial and Commercial Statistics (1903-4) and the Census of 1901.

	Financial and Commercial Statistics.		Census, 1901.	
	No. of Factories, &c.	Daily average of Employees.	Numbers occupied— In Mills.	In Handwork.
Cotton mills	204	186,271	185,876	3,369,967
Jute ,,	38	123,869	78,786	—
Indigo factories	553	81,749	8,249	—
Cotton ginning, cleaning and pressing mills	895	75,625	42,117	243,743
Iron and brass foundries	76	22,338	7,904	620,721 *
Jute presses	155	20,996	5,501	—
Rice mills	112	16,223	42,676	—
Printing presses	107	13,220	23,370	3,295
Silk filatures	63	9,158	10,870	137,323
Tanneries and leather factories	43	7,907	8,928	1,022,373 †
Saw mills	90	7,888	—	—
Lac factories	93	7,635	6,649	—
Brick and tile factories	59	6,435	8,809	79,482
Sugar factories	21	4,896	28,118	91,099 ‡
Coffee works	18	4,726	—	—
Oil mills	99	4,629	5,851	529,421
Paper mills	9	4,523	25,140	3,295
Woollen mills	6	3,041	—	46,634
Woollen weaving establishments not classed as mills	11	4,427	—	27,933
Silk mills	10	2,793	2,428	—
Flour mills	35	2,649	3,882	415,718
Rope works	14	2,535	2,761	233,694
Breweries	27	—	886	—
Aërated water and ice factories	21	756	7,363	—
Distilleries	10	378	4,128	23,840
Petroleum refineries	—	—	3,644	—
Railway and tramway factories	—	—	17,267	—
Engineering workshops	—	—	9,522	—
Miscellaneous	149	17,549	41,604	247,074
Total	2,918	632,116	582,329	7,095,612

* Includes copper and hardware. † Includes leather factories. ‡ Includes sellers.

N.B.—The statistics in the two first columns are admittedly incomplete, and the figures cannot, therefore, be accepted as accurate. The census figures also are of uncertain value. It will be observed that the figures in the Financial and Commercial Statistics give the "daily average" of employees, and not the total number occupied.

APPENDIX III.—Distribution of Indian Cotton Mills in 1903-4.

	Mills.	Spindles.	Looms.	Employés.
Bombay Presidency—				
Bombay City	84	2,638,830	25,359	88,446
Ahmedabad	32	509,928	6,643	20,125
Other Places	25	480,528	3,392	18,584
Total, Bombay Presidency	141	3,629,286	35,394	127,155
Bengal	10	450,962	213	10,230
United Provinces	9	309,620	3,215	8,940
Madras	12	287,706	1,747	12,340
Central Provinces and Berar	9	198,532	2,649	10,606
Punjab and North-West Frontier Province	8	114,008	475	3,201
Ajmer-Merwara	1	12,312	369	708
Total, British India	190	5,002,426	44,062	173,180
Native States	9	145,318	1,020	5,457
Pondichery	5	65,600	1,339	7,634
Grand Total, India	204	5,213,344	46,421	186,271

APPENDIX IV.—Chief Exports of Indian Raw Materials.

	Quantity.	Value.		Quantity.	Value.
		£			£
			Brought forward	—	24,384,960
Cocoanut Kernel (copra) cwt.	353,724	281,640	Hemp, chiefly Sann .. cwt.	477,309	323,590
Wheat „	25,911,312	7,392,640	Hides, raw „	670,792	2,111,690
Sugar, unrefined „	198,005	58,700	Skins, raw „	265,325	1,779,120
Manganese ore „	3,623,789	152,940	Jute, raw „	13,721,447	7,812,080
Tobacco, unmanufactured, lb.	11,367,996	85,750	Lac, Stick and Seed „	6,383	29,280
Bristles and Fibre for Brushes, &c. cwt.	83,258	138,420	Seeds „	24,681,424	9,677,220
			Silk lb.	1,862,316	422,830
Coir „	25,500	15,110	Wax cwt.	6,685	29,410
Cotton „	7,931,075	16,259,760*	Wool, raw lb.	33,234,775	918,260
Carried forward	—	24,384,960	Total	—	47,488,440

* The value of cotton is abnormal, owing to a high range of prices.

APPENDIX. V.—Imports of Foreign Manufactures and Corresponding Indian Exports of Manufactures in 1903-4 (including Government Stores).

	Foreign Imports.	Indian Exports.		Foreign Imports.	Indian Exports.
	£	£		£	£
Arms, Ammunition, and Military Stores	746,000	28,000	Woollen manufactures	1,519,000	183,000
Cotton, Twist and Yarn	1,428,000	5,894,000	Apparel (including Boots and Shoes)	1,389,000	187,000
„ Piece-goods	18,366,000	989,000	Bricks, Tiles, and Cement	170,000	8,000
„ other manufactures	944,000	98,000	Cabinet Ware and Furniture	90,000	24,000
Flax and Hemp manufactures	161,000	1,000	Candles	64,000	60,000
Jute, Twist and Yarn	—	5,000	Carriages and Carts	310,000	—
„ Bags	41,000	3,043,000	Coir manufactures	3,000	319,000
„ Cloth	2,000	3,230,000	Cordage and Rope of Vegetable Fibre	39,000	41,000
„ Canvas, Rope, Twine, &c.	32,000	34,000	Earthenware and Porcelain	190,000	3,000
Silk manufactures	1,222,000	56,000			

APPENDIX V.—*Continued.*

	Foreign Imports.	Indian Exports.		Foreign Imports.	Indian Exports.
	£	£		£	£
Glass and Glassware	674,000	6,000	Tea-chests	92 000	—
Paper and Pasteboard	398,000	—	Wheat Flour	9,000	353,000
Hides, dressed and tanned ..	12,000	410,000	Umbrellas	164,000	—
Skins, dressed and tanned ..	49,000	1,656,000	Wood manufactures	50,000	27,000
Instruments, &c.	531,000	—	Oilcake	—	261,000
Jewellery and Plate..	100,000	15,000	Oils (vegetable not essential)	62,000	556,000
Lac (button, shell, &c.)	—	1,787,000	Metals and Metal manufactures (including hardware and cutlery, machinery and mill-work, and railway plant and rolling stock) ..	14,544,000	90,000
Leather and Leather manufactures	184,000	20,000	Sugar, refined	3,823,000	11,000
Matches	337,000	—	Tobacco, manufactured ..	311,000	54,000
Mats and mattings	18,000	4,000	Malt liquors	373,000	—
Paints, Colours, &c.	285,000	—	Miscellaneous	1,281,000	77,000
Perfumery..	21,000	9,000			
Paper and Pasteboard	398,000	—			
Soap	177,000	2,000			
Stationery..	287,000	—			
Toys and Requisites for Games	182,000	19,000	Total	51,078,000	19,560,000

N.B.—The above list is not exhaustive. Many articles—tea, indigo, petroleum, dyes, tans, provisions, opium, &c.—which are not usually classed as manufactures, are excluded. Some of the imports are re-exported, but not in sufficient quantities to necessitate special mention, with the exception of metals and metal manufactures, £254,000, cotton yarn and manufactures, £916,000, and apparel, £114,000.

DISCUSSION.

HIS HIGHNESS THE CHAIRMAN said they had all listened to the paper with great attention, not merely for the purpose of satisfying their curiosity, but in order to analyse the views expressed by the author. He did not propose to go into much detail, because the subject was an important one, and could not be fully dealt with on the spur of the moment and without preparation. He would, therefore, express a few simple ideas which the audience would take for what they were worth. The subject of the manufactures of India was of vital importance to the future prosperity and progress of the country, and he was glad to find that so many gentlemen in England, both officials and non-officials, were paying attention to it with a view to its solution. What the solution would be remained to be seen. A few years ago at a conference held at Ahmedabad he had the pleasure of delivering his views at some length, and, in order not to inflict them again on the audience, he would refer them to the speech he delivered on that occasion. He thought the greatest want in India was education in its widest sense, and he thought they should look back to the past history of the country in order that the path for the future might be seen. Before the advent, or almost at the beginning, of British administration, India had manufactures of its own which vied successfully with those of the rest of the world. Although the form of government had changed, he could not say that the present inhabitants had lost all the past glories and intellect of their ancestors. Given proper opportunities and facilities, he saw no reason why the descendants of the Hindus of the past should not hold their own in 1905. Difficulties arose from lack of knowledge, not only technical knowledge, but knowledge of the requirements of the world and of the best markets in which natives could sell their products at the greatest profit. How many Indians had any idea that the beautiful lacework made in different parts of India, especially Kashmir, would be valued and appreciated to a great extent in the markets of Europe? If the people did not know where the markets were how could they be expected to persevere with their industries? In order to avoid that difficulty he thought the first essential was to extend the limit of their knowledge; and when that had been done the articles produced in the country would be bought in other countries at a price which would pay the producers ten-fold. Had the Government of India done sufficient to promote technical education; had it exhausted its resources; were there no chances of doing more than they had done? They should congratulate themselves and be grateful to the Government for what it had done; but as an Indian whose interests were bound up with the country he held that the Government had yet much to do; and he hoped the future history of the country would show that the Government had always done its utmost to achieve that goal. He agreed in many respects with the remarks the author had made in connection with

both the skilled and lower classes of labourers in India, but he thought there were many points in favour of the Indian workman which went to accentuate his deficiencies. A man who did his work quickly and with regularity would be more in demand than one who was remiss in those respects. In India the masters were often too lenient; if a man was irregular they put up with him. But in the present days of competition and "push" they could not afford to be so lenient; they must be strict in order to teach workmen to be regular, and in order that they might hold their own in the world. In Baroda he had made several experiments, and had advanced money to different traders and merchants in the hope that they in their turn might make loans to support and encourage industries. The experience he had gained in that respect was not an uncommon one. Government was probably one of the worst agencies to manage industrial undertakings; and Baroda had been no exception. He hoped, however, that the failure in Baroda would not discourage other States or the British Government. Each State had its own difficulties, and particularly the Native States. The labour market was not at their call, and they could not employ the best educated and most intelligent men at their will; but Governments, which had greater facilities in that respect, could do such things with greater success than small States, which at present merely carried on the primitive functions of government. The people were satisfied with the exercise of primitive functions of government, because they were ignorant of their position and rights; they were ignorant of what they should demand, and the manner in which they should demand it. Ignorance was the problem which had to be fought against everywhere; if that were removed he saw no reason why the patient, sober, clever, intellectual labourers of India should not be able to hold their own with the labourers of the rest of the world. If many people in this country saw the beautiful designs and finished articles which were made in Kashmir they would be astonished at the amount of time and patience that were put into the work. If the artificers only had men to guide them who knew where the articles could be sold he was perfectly certain that Kashmir would have hundreds of factories with thousands of clever workmen who would do the utmost credit to any employer. Baroda could not boast of many mills; practically there was only one, which he started himself as a Government concern. He started it, not in order to increase the revenue or to fill the coffers of the State, but in order that it might be an example or lesson to the people of the country. That mill had been worked with more or less success, not probably with as much success as would have been attained had it been a private enterprise, but it had done as well as could be expected under the circumstances. Just before leaving India he sold it to a citizen of Baroda, and it was now being worked privately, an object he had had in view for some time. He was glad it had been taken up by a private individual, not because he was able to get rid of the responsibility of looking after the mill, but because it showed that the people of the locality were becoming more enterprising and confident of being able to manage affairs which really pertained to them. Before leaving India he also had several offers from different people in the State saying that they were anxious to open mills; he was cautious, not suspicious, and until he saw the mills working he would suspend his judgment. He told the people that he would be the first to give them as much encouragement as he possibly could. The greatest encouragement a Government could give was a minimum of taxation and of Customs duties. With facilities in the way of education, with knowledge of the world, with security, liberty, and right in property he thought the Government could do a great deal. In that respect the Native States had no reason to complain, but as an Indian he thought the Government should give them still greater knowledge in order that they might be able to appreciate the good that was being done, and with that increased knowledge be able to protect their own interests. With increased knowledge they must also have increased interest and increased power in the management of State affairs. In India, where every initiative had been crushed out for centuries, it was necessary, in order to encourage the people, to give them scope for enterprise, and to treat their failures up to a certain extent with leniency. They should be told not to commit the mistakes again in order that they might rise to a higher level in the future. There was no greater teacher than experience, and if the natives were given scope and a legitimate share in the affairs of Government, that experience would stand them in good stead in the management of their own affairs which belonged to the private citizen. He thanked the audience for the patience and kindness with which they had listened to his remarks, which had been unfortunately lacking in the preparation which he would have wished to give them, and, in conclusion, he most heartily thanked Mr. Tozer for his learned and eloquent paper. The subject was complicated, and people held different views, but in the multiplicity of opinions he thought some simple solution might be found. With that view he thought they should always be prepared to listen with an open mind to any opinions that might be expressed, and ultimately come to the conclusion which was most consistent with their own knowledge and conscience.

Sir George Watt, C.I.E., said that in dealing with the subject of the handicrafts of India it was customary in English audiences to hear caste extolled into a feature of the greatest magnitude and importance, and as practically determining the commerce of India. With that view he did not agree. He had travelled all over India and devoted a great many years to the study of its industries, and had

come to the conclusion that some of the most important and pressing aspects of Indian enterprise centred far more round the great European than Native industries. That might seem very contradictory to what had been said in the paper, but he thought that when it was looked into carefully it would be found true. The Chairman had referred to technical education as one of the most pressing necessities of the future. Technical education essentially meant the development of the industries, on lines not familiar to the natives of India themselves, but in the methods, appliances, and means practised in Europe. He, therefore, held very strongly that the industries of India should be more studied on the lines of modern commerce than as ancient industries. Comparatively few of the crops cultivated in India, in the present day, were indigenous plants, and many had been introduced within comparatively recent times. That fact alone showed that India was undergoing a radical change in every direction. In the same way the handicrafts could not be practised as they had been for centuries, if India ever hoped to compete against the world. Mention had been made of the efforts undertaken by the Government in some districts to improve hand-weaving. He thought it was very desirable if possible that the weaving should be improved, but it must be remembered that India had to compete against Manchester, Germany, America, France, Japan, and other countries that were not using the looms made by their grandfathers or great-grandfathers, but the most advanced and improved machinery the world possessed. If the people of India were taught what our grandfathers had abandoned, neither the foreign, commercial, nor the interests of the people of India would be advanced. Some scheme would have to be developed which would embrace not only technical education, but a system of extending a helping hand to enable people to start on the lines of success, not of failure. The bulk of the modern industries of India were foreign. The present cotton industry, for example, was a new industry. Mr. Tozer had referred to the fine work turned out by the hand-looms, but it was a fact that the finest muslins made in Dacca were only four hundreds, and machinery turned out six hundreds. It was a fact that hand-labour could not do what machinery could do, while machinery could do anything that the hand could do. The only limitation was in the market. If an article was too unimportant to command a manufacturer's interest then it would remain, but if it would give profitable returns one might depend upon it that European machinery and European brains would compete against every handicraft, and had done so. He, therefore, thought His Highness, in referring to technical education, had struck the keynote of the whole future of India. It was a pressing necessity that the people should be taught how to compete against importation. Three million bales of cotton were produced annually in India, of which half was exported as raw cotton. The other half was almost entirely used up, not by the hand-looms but by the power-looms. Half of the manufactures of the looms—yarns and piece goods—were exported, so that only a quarter of the total cotton crop of India remained for the people. Three-quarters of the people who were engaged in this modern cotton trade would, therefore, be deprived of their livelihood if the cotton mills were closed for export manufacturing purposes. The most important interest in cotton was, after all, its agricultural value. A great portion of the yarn spun in power mills was sold to the hand-weavers of India, and a large amount of yarn was also imported for the purpose of feeding the hand-looms, the goods turned out by the hand-weavers finding a ready market. Hand-woven goods were distinctly preferable in many respects, especially when they were made up into goods of a special kind with which European competition was not likely to interfere. The whole subject turned on the point that the bulk of the natives were using European spun yarn, either spun in England or in India by power-looms. The hand-spinning of yarns in India was practically a thing of the past, and the hand-looms were also bound to become things of the past, though this was doubtless much to be deplored. It was, therefore, of the very greatest importance to India that the Government should endeavour by some means to educate the people how to compete against foreign importations. The most important step that had been taken for a long time was, he thought, that made by the Viceroy, quite recently, when he founded a Commercial and Intelligence Department. He thought the people of India had every right to congratulate themselves that a step in the right direction had now been taken, and that the Commercial Department would do great service to the country.

Mr. M. C. MALLIK said he was glad of the opportunity of being permitted to express the pleasure he felt, which was doubtless shared by all present, at seeing his Highness presiding at a meeting connected with India in the metropolis of the Empire. It showed that the union and solidarity of the Empire were being strengthened by forces beyond the powers of short-sighted politicians to hinder. The subject of the interesting paper was of profound concern to all interested in the welfare of India and of the Empire as a whole. It had for years been a general complaint that the indigenous industries of India were decaying, that manufactures were languishing, and that all kinds of artistic work handed down from a remote and glorious past were, through want of encouragement, dying out. Each man, official or non-official, European or Asiatic, might give what explanation he liked in regard to the causes of that decay, but it seemed to him that by the most inscrutable dispensation of Providence the destinies of the ancient land of the Aryans, perhaps the most conservative on the face of the globe, had been linked with those of the land of the Anglo-Saxons, now the most progressive power amongst mankind.

The manufactures of India had, like everything glorious, in the past been taking a long slumber, and through the instrumentality of England pressure had been brought to bear upon that long-dormant force to wake it up to life and activity. A halo of glory was now in store for those who would guide the just-reviving forces of national regeneration, amongst which the revival of national industries must hold a conspicuous place. The sun after being under a cloud for centuries was now rising over Asia, and owing to the attainment by Japan of a leading position in the world it might be expected that Asiatic manufactures and fashions would be sought after by all the more advanced and wealthy nations of the world. It behoved India not to lag behind. The importance of India to the Empire might be imagined by a study of the statistics of trade. It would be seen from the statistics that the trade of India with the United Kingdom was more than equal to that of any two of her rivals, the colonies, combined, and one could imagine what that trade would be if instead of being forsaken, India were happy and prosperous under a liberal *régime*. The author had referred to the work done by the labouring population of India, and had stated that there was a disposition among the workers to do less work for more pay. He was not sure that that weakness was confined to India alone. It was well known that Baroda, under the enlightened rule of his Highness, had become a model State, and in order to give the same impetus to advancement in every department all over India, the officials, from the Secretary of State and the Viceroy down to the lowest policemen and all non-officials, from the great chieftains to the humblest peasant, should feel that the interests of India and England were identical, and that one could not be injured or benefited without corresponding injury or benefit to the other, and that impartial justice and a sense of security were the primary conditions of national advancement in every latitude.

Mr. TOZER, in reply, thanked the members for the kind reception they had given to his paper. He was sure everyone would agree with his Highness's eloquent speech with regard to the promotion of education. The Government of India had already done a great deal in that direction in the last few years, especially in the promotion of technical and industrial education. Progress, however, must necessarily be very gradual, and, as was found in this country, the financial aspect of the matter had to be very carefully considered. With regard to the subject of Indian labour, he hoped he did not insist too strongly on one side of the question. Everyone knew how patient and industrious the Indian labourer was. When he dealt with certain defects he was thinking more particularly of factory workers, and what he said concerning them was accurate. He agreed entirely with Sir George Watt's remarks on the purely economic aspect of handicrafts, and, in the last paragraph of the section dealing with that subject, he anticipated what Sir George had said. But he had added that this was as much a social as an economic question, and the proposals for improving hand-looms and for aiding handicrafts generally had for their object to tide over the period of stress from which the people were suffering. Moreover, the decay of the handicrafts meant the throwing out of employment of several million workers, and it was very important socially that those people should not be too rapidly forced to find other occupations. Even in a country so advanced industrially as Austria-Hungary the State is endeavouring by positive measures to arrest the decline of the small industries. It aims at correcting the antiquated notions of the small mechanic and at educating him in modern methods of production by systematic courses of instruction. Further, under the auspices of the Ministry of Commerce, he is assisted in purchasing small machines and tools (see Consular report on Austria-Hungary, No. 3,343, of 1905).

Sir WILLIAM LEE-WARNER thought all present would go away from the meeting with the conviction that a great work had been done in India, but that a greater work remained to be done, in the doing of which both Indian and Englishmen must work together and use their utmost endeavours. It had always been the desire of the Society of Arts to develop its Indian branch, and several papers were read every year on Indian subjects in order that in the Mother of many capitals throughout the world there might be a more extended knowledge of that great part of the British Empire, the Indian Empire. They, therefore, particularly welcomed the help rendered by his Highness in taking the chair, the more so because he was present at some sacrifice, having come home in order to recruit his health. Although his Highness sought leisure he had been willing on the present occasion to appear before a large audience and show that he took an active interest in the work the Society was doing, of which he was glad to say his Highness's brother was a member.

The CHAIRMAN thanked Sir William Lee-Warner for his exceedingly kind words, and said that in conclusion it was his very great pleasure to propose a vote of thanks to Mr. Tozer for his exceedingly interesting paper.

The resolution having been carried unanimously, the meeting terminated.

Mr. ALEXANDER ROGERS writes:—The paper read before the Society on the 11th ult. was excellent as far as it went in placing before us the general position of Indian manufactures, but failed entirely to point out how that position could be improved in the future by stimulating other industries indigenous to the country, and thus adding to the means of employment and wealth of the people. One of the

principal wants necessary to be provided for is the development of industries to take the place of agriculture and afford means for the subsistence of agriculturists in times of failure of crops and famine, at which periods they have nothing to fall back upon to earn a livelihood and consequently starve, and it is with a view to suggest several perfectly feasible methods by which this state of matters can be improved that I now address these few words to the members of the Society. The first of these is the improvement of paper-making. The use of writing paper, produced by native methods, is, of course, universal, but the quality of the material made is capable of very great improvement by the most ordinary attention and care. At present, I believe, no precautions whatever are taken to ensure the cleanliness of the rags out of which the pulp is made, the consequence being that the paper is dingy, dirty, and full of impurities which could be obviated by simple thorough washing in pure water before they are converted into pulp. The paper referred to contained no statistics with regard to this universal industry, and as there must be many millions of tons manufactured by crude native methods throughout the country every year, it may be imagined what a vast scope there is for the employment of capital, native as well as foreign, in this one industry alone. Among the industries now in existence enumerated in Mr. Tozer's paper I find no mention made of another very universal one connected with the improvement of leather, in which there is a very large field for the employment of capital, viz., in the preparation of the bones, horns and hoofs of the animals from which the hides for the leather are obtained. I believe the horns and hoofs are to some extent made use of, but by what agency they are collected I am not aware. The bones, which would form the base of the valuable agricultural manures so much needed throughout the country, are almost entirely wasted. In now speaking of the wild or Tasar silk industry, which would afford almost unlimited scope for the employment of capital, I refer specially to the Bombay and Madras presidencies, in which, strange to say, the example of Bengal, the Upper Provinces, and Kashmir has not been followed, although the worm—of which the moth bears the entomological name of *Antherea Mylitta*—is indigenous to both of them. It does not require the mulberry for its food, but lives on the leaves of some of the commonest jungle trees, so that the introduction of the culture would require no expense whatever. If paid for the collection of the cocoons, the Bhils, Warlis, Kátkaris, Kolis, and other wild tribes would find congenial employment in placing-out the eggs on the various trees in the jungles, and, with the assistance of their women and children, in keeping off the birds which would otherwise prey on the growing worms until they formed their cocoons on the branches. It would cost no long time and but little expense before the women would learn to spin off the silk from the cocoons and find remunerative employment, especially in time of famine, when agriculture failed them, to gain a livelihood. Silk manufacturers would soon establish depôts at village fairs and market places where this silk, for which there is an almost unlimited demand in England and on the Continent, particularly in the south of France, would find ready purchasers. A large and growing industry would thus be started which would prove of inestimable benefit to the country and to the agriculturists generally when the monsoons failed and their ordinary sources of employment and wage earning gave out. The few things that are here pointed out are ready to hand and need but little organisation and capital to carry out without delay. There are, no doubt, numerous other indigenous industries which could be started with the aid of a little thought, to the great good of India and her people; and it is to be hoped the attention of capitalists will soon be directed towards them.

ELECTRIC LIGHTING IN ST. PANCRAS.

At present discussion centres largely upon electric lighting, and within the metropolitan area St. Pancras was the pioneer borough in this direction. It is now more than thirteen years since the borough authorities determined to supply St. Pancras with the electricity it required. At first progress was slow and failures many. That was inevitable with a new enterprise of the kind; but if the Council's figures are to be accepted, with the exception of the first year (1892), when the year's working showed a loss of £1,543, and in 1896, when there was a loss of £1,950, each year has shown a profit, which, in 1904, was no less than £20,583. The tables (p. 785), which are official, show the progress of the undertaking since its commencement.

It will be noticed that whilst since 1896, and with the one exception of 1903, there has been a steady reduction in the average price obtained year by year, the revenue has continuously and rapidly increased, and the net profit is now very large. From September last the maximum demand system was reduced from 6d. per unit the first hour and 3d. after, to 6d. per unit the first hour and 1½d. after; the flat rate was reduced from 5d. to 4d. per unit, and the power supply from 2d. to 1d. per unit. The basis of charge for public street lighting has also been reduced. There are now only eighty possible consumers for motive power remaining in the borough to be secured as customers. Three great railways—the Midland, Great Northern, and North-Western—have their headquarters within the borough, which would naturally like to supply them with motive power, but they will probably prefer to remain their own suppliers. The large reduction in the cost of production during the last three years is due to better load factors, improved facilities for manipulating machinery, and the greater efficiency of machinery. St. Pancras has done much to weed out old

machinery, but it is necessarily at a disadvantage as compared with boroughs which went into the business later, and were consequently enabled to avoid some of the mistakes of the pioneer borough. The financial position of the undertaking in St. Pancras is sound. The total capital expenditure stands at £460,368, last year's profit, as stated, being £20,583, and with two exceptions every year since the start has shown a profit. It is not surprising that some members of the Council were desirous of allocating a part of the profits in relief of the rates, but we read in the report that "the Council endorsed the committee's view that the soundest policy, having regard to the amount of the capital expenditure, is to consistently transfer to the reserve fund all available profit until that fund has reached the limit allowed by Parliament, namely, ten per cent. of the capital expenditure. With the two-fold object of building up a substantial reserve fund, and paying towards the relief of the rates, the committee recommend the Council to reduce the charges for supply, believing thereby that the objects desired will be earlier brought about by the increased business that will naturally follow the lowering of the price."

The St. Pancras authorities claim that at the price now charged in the borough electric light is as cheap as gas (not incandescent), and the committee hope soon to be in a position to reduce the price another halfpenny, say to 6d. and 1d. But there can never be very general use of electricity by the small householder until he is relieved of the cost of wiring. He may wish to use the electric light rather than gas, he may believe that having regard to its greater cleanliness, and other advantages, it is cheaper than gas, but he will not spend £10 or £15 for an installation in another man's house, and may not be prepared to do so even in his own. The boroughs are alive to this difficulty, and the London County Council is now asking authority from Parliament to make loans to borough councils for the purpose of free wiring. If Parliament assents, as it is likely to do, there will be something like a revolution in house lighting in London. The electric lighting of the ordinary residential house will then soon become general.

Mr. Sydney Baynes took over the work of Chief Engineer in 1895.

CORRESPONDENCE.

BRITISH WOODLANDS.

Only ill-health has hindered my writing ere this to thank Sir George King for his vindication, in the Society's *Journal*, of the 5th inst., of General Michael's meritorious services in the promotion of Forest Conservancy within the British Empire. I ought myself to have been the first,—and would have been but for long-engrafted and now most disabling malaise—to couch a lance in support of his claims to recognition in this connection; but I am indeed grateful to have been anticipated in the duty by Sir George King, who is far better qualified for its dis-

charge,—except that he cannot surpass me in respect for General Michael's work in Imperial Forestry, and reverence for his character as "an officer and a gentleman." I venture to express my entire concurrence with Sir George King's authoritative appreciation of General Michael's paper on "Forestry and Forest Education," published in the Society's *Journal* of the 21st December, 1894: and I may add that when the Report of the Select Committee of the House of Commons, referred by Sir George King, was published in 1902, I was both surprised and disappointed to find that none of the admirable suggestions made in General Michael's paper had been referred to by the Committee, notwithstanding that the Committee reproduced in the Appendix to their Report quotations from the writings of others of far less value and interest than many they might have given from General Michael's paper. I know that General Michael's paper was in the hands of the Committee for I sent a copy of it to Mr. Munro Ferguson, M.P., the Chairman of the Committee, who acknowledged the receipt of it in most cordial terms. The simple matter of fact is that during the later decades of the last century it became the fashion in certain quarters to regard the British foresters who preceded the expert German foresters, in India, as the "mere amateurs." In my humble opinion, corroborated by that of Anglo-Indian officials of the highest administrative reputation, it was by these "mere amateurs" that the wide and solid foundations of Forest Conservancy were laid deep and fast throughout British India, and notably by Michael and Cleghorn in Madras. These thoroughly practical men prepared the way before them for the specially trained scientific Germans who speedily raised the now regularly organised Forestry Department of the Government of India to its present state of brilliant efficiency, making it the envy of our Imperial Colonies, and the admiration of the civilised world. Cleghorn was a connection by marriage with my family, and I recollect when I was a medical student at Edinburgh, his saying, while there sometime between 1848 and 1852, quoting I fancy from Seneca:—A forest so long in forming may become a waste of ashes in a moment—"Momento fit cinis diu sylva." Considerations of this kind are now leading to the establishment of a Forestry Department under every Government of the civilised world, and the aditial steps in this direction in British India were taken by Michael and Cleghorn. That was their literal, definite, and specific achievement, and is their title to the approbation and praise of their official colleagues and fellow countrymen, and the more this is ignored or gainsaid, the more firmly will it be established in its truth and justice beyond all contemporary cavils.

GEORGE BIRDWOOD.

Empire Day [24th May], 1905.

GENERAL NOTES.

SOUTH AUSTRALIAN PHOTOGRAPHIC SOCIETY.—The annual exhibition of photographic work for the present year will be opened on Monday, 11th September. A bronze medal is offered for competition in each of the nine classes of Section 1, or in lieu thereof the sum of one guinea. A silver medal is offered for competition in each of the eight classes in Section 2. The society offers a gold medal as a champion prize, in lieu of any other prize for the best picture in Sections 1 and 2, such picture to become the property of the South Australian Photographic Society. All exhibits must be delivered at the South Australian Society of Arts' Rooms, Institute, North-terrace, Adelaide, not later than 5 p.m. on Wednesday, August 30, 1905.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JUNE 5...Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Engineers, in the Theatre of the United Service Institution, Whitehall, S.W., 7½ p.m. Messrs. Charles Scott Meik and Walter Boer, "The Improvement of London Traffic."

Chemical Industry (London Section), Burlington-house, W., 8 p.m. 1. Mr. R. W. Sindall. "The Manufacture and use of Art Papers." 2. Messrs. Clayton Beadle and Henry P. Stevens. "The Influence of Gelatine Sizing on the Strength of Paper."

Geographical, University of London, Burlington-gardens, W., 8½ p.m. Colonel P. H. H. Massy, "Exploring Journies in Asia Minor."

Actuaries, Staples-inn Hall, Holborn, E.C., 5 p.m. Annual Meeting.

TUESDAY, JUNE 6...Royal Institution, Albemarle-street, W., 5 p.m. Rev. Henry G. Woods, "Velasquez." (Lecture III.)

Central Chamber of Agriculture (at the HOUSE OF THE SOCIETY OF ARTS), John-street, Adelphi, W.C., 11 a.m.

Zoological, 3, Hanover-square, W., 8½ p.m.

Colonial Inst., Whitehall Rooms, Whitehall-place, S.W., 8 p.m. Prof. Alleyne Ireland, "The British Empire in the East."

WEDNESDAY, JUNE 7...Geological, Burlington-house, W., 8 p.m.

Royal Archæological Institution, 20, Hanover-square, W., 4 p.m. Miss Josephine Knowles, "Symbolism in Norman Sculpture at Quenington, Gloucestershire."

Obstetrical, 20, Hanover-square, W., 8 p.m.

Victoria Institute, 8, Adelphi-terrace, W.C., 4 p.m. Annual Meeting.

THURSDAY, JUNE 8...Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Royal Institution, Albemarle-street, W., 5 p.m. Prof. J. A. Fleming, "Electromagnetic Waves." (Lecture III.)

Mathematical, 22, Albemarle-street, W., 5½ p.m.

East India Association, Caxton Hall, Westminster, W.C., 4 p.m. Mr. F. H. Skrine, "Hydrophobia in the East."

FRIDAY, JUNE 9...Royal Institution, Albemarle-street, W., 9 p.m. Sir Wm. White, "Submarine Navigation."

Astronomical, Burlington-house, W., 8 p.m.

SATURDAY, JUNE 10...Royal Institution, Albemarle-street, W., 3 p.m. Mr. H. Savage Landor, "Exploration in the Philippines." (Lecture II.)

Journal of the Society of Arts.

No. 2,743. VOL. LIII.

FRIDAY, JUNE 16, 1905.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

NOTICES.

ANNUAL GENERAL MEETING.

The Council hereby give notice that the One Hundred and Fifty-first Annual Meeting for the purpose of receiving the Council's Report and Treasurers' Statement of receipts, payments, and expenditure during the past year, and also for the election of officers and new members, will be held in accordance with the By-laws on Wednesday, 28th June, at 4 p.m.

(By Order of the Council),

HENRY TRUEMAN WOOD,
Secretary.

CONVERSAZIONE.

The Society's Conversazione will be held, by arrangement with the Council of the Royal Botanic Society, in the Gardens of that Society, Inner-circle, Regent's-park, on Tuesday evening, the 4th of July, from 9 to 12 p.m.

The central portion of the Gardens only will be used. The Gardens will be illuminated with coloured lamps, and also by the Kitson Incandescent Oil Light. The Conservatory and the Club-house will be open.

The Reception, by Sir William Abney, K.C.B., F.R.S., Chairman, and the other Members of the Council, will be held at the entrance to the Conservatory, near the Broad Walk, from 9 to 10 o'clock.

The Tropical House, containing the Giant Water Lily (Victoria Regia), Banana, and other interesting tropical plants, will be open to visitors.

An Exhibition of Growing and Cut Roses and other Flowers will be arranged in a marquee in the grounds by Messrs. W. Paul and Sons, of Waltham Cross.

An Exhibition of Economic Plants, &c., grown in the Gardens of the Royal Botanic Society, together with specimens from that Society's Museum, will be on view in the Corridor.

A collection of Liliums in Pots will also be arranged in the Corridor.

A Selection of Music will be peformed by the String Band of the Royal Artillery in the Conservatory, and by the Band of H.M. Grenadier Guards in the Gardens, commencing at 9 o'clock.

Two performances of Selections from Pastoral Plays will be given in the Gardens by Mr. Patrick Kirwan's Idyllic Players at 9.30 and 10.45 p.m.

A concert and entertainment, including a scene from "The School for Scandal," will be given in the Club-house, from 10 to 10.45 p.m.

Light refreshments (tea, coffee, ices, claret-cup, &c.) will be provided.

Each member is entitled to a card for himself (which will not be transferable) and a card for a lady. These cards are now in course of issue. A limited number of tickets will also be sold to members of the Society, or to persons introduced by a member, at the price of 5s. each, if purchased before the day of the Conversazione. On that date the price will be raised to 7s. 6d.

Members can purchase these additional tickets by personal application, or by letter addressed to the Secretary at the offices of the Society, John-street, Adelphi, W.C. In all cases of application by letter a remittance must be enclosed. Each ticket will admit one person, either lady or gentleman, and must be signed by the member applying for it.

Tickets will only be supplied to non-members of the Society on presentation of a letter cf introduction from a member.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

Thursday afternoon, May 18; Sir DENNIS FITZPATRICK, K.C.S.I., in the chair.

The CHAIRMAN said that Dr. Creighton was so well known by his works that he hardly needed an introduction. It might be mentioned, however, that the paper Dr. Creighton was about to read embodied the results of a special journey he took to India for the purpose of studying the external aspects of plague in that country.

The paper read was—

PLAGUE IN INDIA.

By CHARLES CREIGHTON, M.D.

Eight years ago the subject of plague in India was brought before this Society in a paper by Dr. Herbert Birdwood, which dealt with the first epidemic in Bombay city in 1896-97 (*Journal*, Feb. 28, 1898, vol. xlvi. p. 305). Dr. Birdwood's intimate account of the beginnings of the infection, of its rapid extension, and of the efforts made to cope with it, will remain a document of importance, both by reason of the fresh impression of so novel an experience in an Indian city under British rule, and also because it was the first chapter of what is likely to prove a long history. At the date of the paper, a second plague-season in Bombay had begun, which proved to be more disastrous than the first; the cities of Poona and Karachi were also infected severely, and there were many minor centres along the whole coast northwards to Cutch, and in the transmontane districts of Satara and Sholapur to the south, as well as two small spots of plague more than a thousand miles away in the north-west, one around Hurdwar, and the other in villages of the Jullundur doab. By that time the Government of India was naturally alarmed at a threatened invasion of the whole country, and appointed in August, 1898, a Commission of five to conduct an investigation specially defined as of a scientific character, into origins and ways of spreading, as well as into the mode of treatment by serum-inoculation, and the mode of prevention by inoculating a solution of dead bacteria. That Commission is now ancient history; so that I am at liberty to remark, that there was not a single epidemiologist upon it, and that its "scientific character" was ruined by two causes: first, because the two medical members who wrote the Report put aside such evidence as did not come within their bacteriological point of view, and, secondly, because the two departmental members were disinclined to look into the errors or omissions of sanitation which had prepared the way for plague, especially in Bombay city. However, the witnesses contrived to say a good many things, *proprio motu*, which make the three volumes of evidence valuable and interesting reading.

PRESENT AREA.

When the Commission began its work in November, 1898, the centres of infection were many and widely scattered, so that sittings to take evidence were held at places as far apart as Bangalore and Lahore in one direction, Calcutta and Karachi in the other. But the infected area was still comparatively small. There was no plague in the Madras Presidency, none in Bengal excepting at Calcutta, none in the United Provinces excepting over a small part of the district of Saharanpur, and none in the Punjab excepting in one small spot of the Jullundur doab. During the next six years the area has been extended enormously, but still within notable limits. The Madras Presidency has continued almost entirely free, and, what is more remarkable, also the whole of Orissa, Lower Bengal, and Assam. It is the North-Western plains that have become the chosen seat of plague, from the Jhelum river in the north to a point on the Ganges about 300 miles above Calcutta, while the original area in the Bombay Presidency has extended.

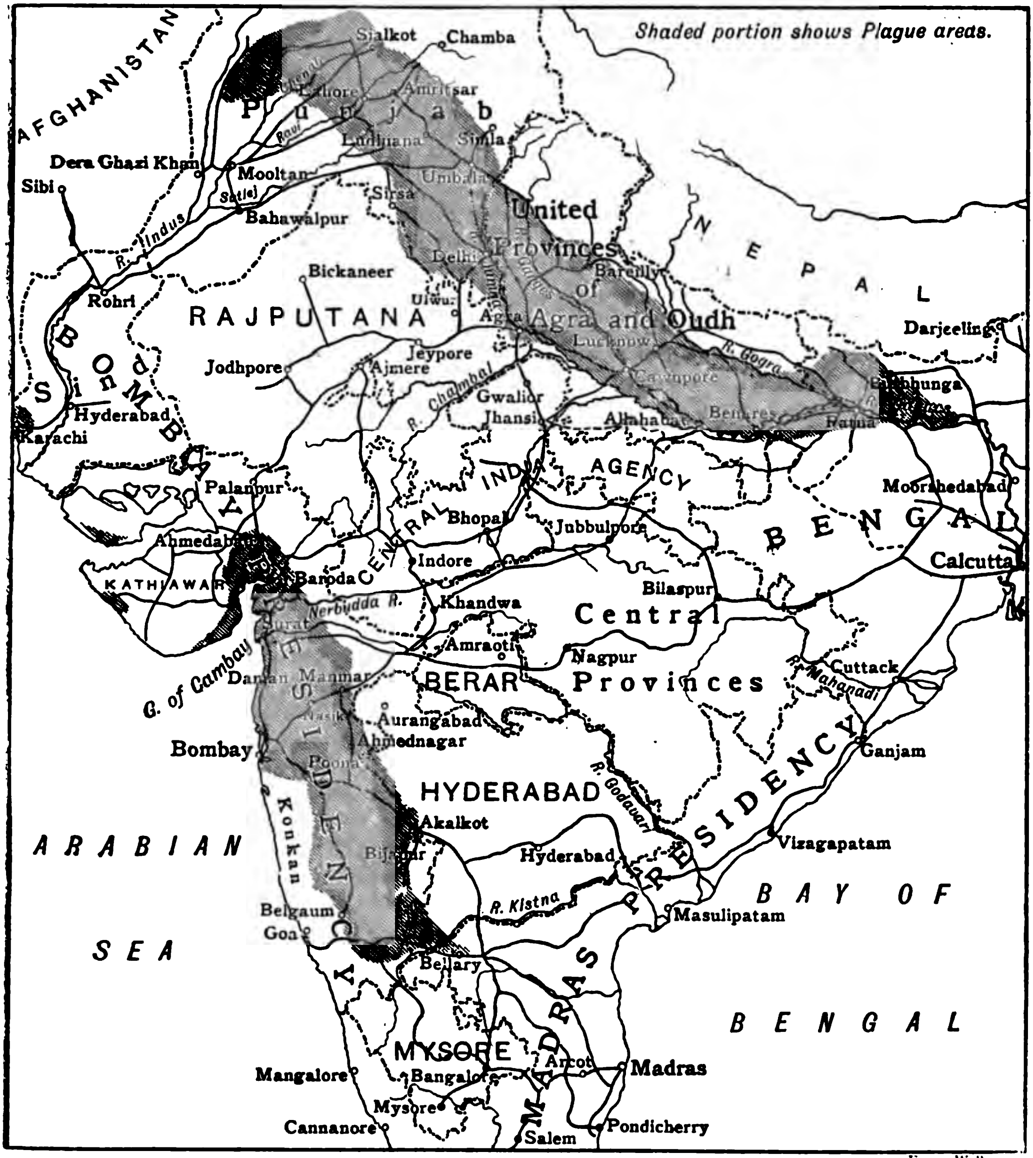
Those regions of India which have been proved by an experience of nine years to be the great seats of plague are shaded on the map. (Fig. 1.) They look somewhat compact and continuous in two divisions—one the plains of the North-West, the other the alluvial valleys of the Deccan and Gujarat. This does not profess to be an exhaustive map of plague. For example, there have been many deaths from first to last in the Native States of Mysore, Hyderabad, Indore, and Rajputana, and in the British Central Provinces, but far more in the cities, such as Bangalore, Indore, and Jubbulpore, than in the villages. Also in Sind, Karachi was not the only place infected at first, although it remains almost the only place now. If I had shaded every one of those extensive and sparsely-populated

tracts of country where plague has even been in those years, I should have produced a confusing, if not a misleading effect. Without being exhaustive, the blue colouring in the map on the wall shows fairly enough where the interest really lies, and it covers those parts of the Bombay Presidency and of the North-West to which I limited myself during a recent tour of three months.

SOME FIGURES.

I do not intend to be statistical, but a few round figures may be given to bear out this colouring of certain regions on the map. First, as to the dark area in the south of the Bombay Presidency. The three districts of Satara, Belgaum and Dharwar, and the Native State of Kolhapur, have each returned an almost equal total of plague deaths during the last

FIG. 1.



MAP OF INDIA SHOWING PLAGUE AREAS.

four years, viz., 120,000, being an average of 30,000 a year for each in a population of about a million. The adjoining district of Bijapur had over 20,000 in each of the two last seasons, while Sholapur and Khandesh have each had one season of 25,000 in the more recent period. But in the Punjab those large annual totals have been exceeded in several districts: Sialkote had 50,000 deaths the season before last, Ludhiana almost the same number three years ago, Gujranwala 30,000 last year and 45,000 the year before, whilst the oldest centres of infection in the Punjab, the adjacent districts of Jullundur and Hoshiarpur have shown a steady increase for three years running, reaching last year to 30,000 plague deaths in the one and 25,000 in the other, with the promise of quite as many this season when the returns are completed. For a single week last year in the end of April or the beginning of May, which is the height of the plague season in the Punjab, four of the districts returned 4,000 each, while half a dozen more returned from 2,000 to 3,000. In the United Provinces until this year no district has come near to those enormous weekly maxima; but at length Muttra has reached 4,000 plague deaths in a week, while Ghazipur and Agra have each had a highest weekly total of about 1,600. In Behar the worst district has been Saran, the poorest and most crowded part of India, which has reached 2,000 a week, while two or three other districts of the same Patna division have had each over 1,000 a week at the height of the plague season. Last year the plague deaths in all India totalled about a million, of which nearly 400,000 came from the villages of the Punjab and 300,000 from the villages of the Bombay Presidency. Last year the worst week was that ending the 2nd of April, with a total of 46,320 plague deaths. This year the week ending 1st April had a total of 57,702, the increase being more than accounted for by the unusual severity of the infection in certain districts of the Agra province, and in the adjoining districts of the Delhi division of the Punjab, as well as by the extension of area eastwards in Behar.

Plague an Old and Well-understood Infection.

To an epidemiologist this enormous prevalence of plague steadily from year to year among the rural population of India is perhaps the most remarkable phenomenon in his science. It is all the more remarkable that we have never thought of India as a great seat of plague in former times, such as Lower Egypt, Syria, and Irak had been during many centuries of Mohammedan rule, and that we were beginning to look upon plague as a thing of the past everywhere. In writing the article on "Quarantine" for the *Encylcopædia Britannica* twenty years ago, I gave nearly all the space to yellow fever and cholera, remarking of plague that "for many years it has ceased to have any practical interest in this connection," although it had been the original object of all the quarantine laws of Europe. And to show that I was not singular, the paragraph on port quarantine in the Bombay Sanitary Commissioner's Report for 1887 has this sentence:—"Plague or yellow fever have never to my knowledge existed in Bombay, and are not in present circumstances ever likely to be there met with" (T. G. Hewlett, l.c. p. 82). The outbreak in Bombay nine years ago was a surprise; but the greatest surprise of all, in a historical sense, has been the endemic settlement of the infection in the plains. This is, indeed, a real novelty of the present situation to epidemiologists, as well as a very serious practical matter; but, for the rest, plague is a very ancient disease, and, I take leave to say, very well known in its type and in its habits to those who are competent in such matters. There is just as little mystery about plague, and just as much, as there is about cholera, or yellow fever, or typhus, or enteric; and there is actually less mystery about it than about those everyday domestic incidents, measles and scarlatina. What then is the meaning of the claptrap about "our ignorance of plague?" So far as I can understand, it has arisen from the fashion of thinking bacterially about diseases, which the public and the newspapers have adopted. Bacteriologists, when asked to explain plague, are found to be not so lucid as usual; they are at fault in the pursuit of the bacillus outside the body; it runs to earth and gets lost in a crowd of other bacteria in the soil, or disguises itself as a saprophytic mould, or perishes outright in the struggle for existence, although there is no doubt about the infection remaining in the ground all the same. Hence, perhaps, the impression that more bacteriology is necessary before anything practical can be done.

Recent Scientific Developments.

As plague is not found to be contagious from person to person except in its pneumonic

variety, everyone sees that the interest must centre in the infection outside the body. In that connection research in India has added only two novelties to the older body of doctrine, both of them of the minor kind. No one can deny, although some would if they could, that the regular way of receiving the infection of plague is by the breath; but inasmuch as rats in a laboratory can be made to take plague, or something like it, by inserting a culture of bacilli at a puncture of the skin, so it is sought to prove that there may be something corresponding in human experience. One theory started in India is that the infection may enter through wounds of the feet, as the people of that country so often uncover their feet ceremonially, and so many of them go barefoot for want of shoes. This theory is of course inapplicable to European plague, for example, the Great Plague of London in 1665. But there is another theory devised to give moral support to the inoculation experiment on rats, which implicates the rat himself; it is, that the fleas which infest the rat may introduce infection through fleabites on the human skin. The Austrian Plague Commission, which was the first in the field at Bombay in 1897, had already considered whether mosquitos might not carry plague infection, for example, in the plague hospital (where they abounded), from a patient to a nurse; but they found that it was not so, although everyone was bitten.

Various other insects were next thought of, and at length the interest has centred in fleas as possible carriers of infection from the rat. Researches of a very minute and technical kind were started by this hypothesis, on the lines of the well-known microscopic researches on mosquitos. Captain Liston has conducted, in India, a large amount of research upon the fleas which infest the rat. The question next arises, whether those are the same species of fleas which produce the human flea-bites; then there is the question whether those who take plague had been bitten by fleas in matter of fact; and, lastly, the question of microbes in the fleas. All this is, no doubt, a very promising field of academic inquiry; and I am given to understand that the scientific expedition which has been announced with a flourish of trumpets as about to proceed to India "to make a thorough investigation into the causes and origin of plague" is really going out to work in the laboratory at Kasauli, with a view to settling all those open questions in the hypothesis of flea-bites.

Plague Localities.

Just as in a well-known paper read before a certain scientific club, "the theory of tittlebats" was joined naturally to their habitat, the Hampstead Ponds, so I would wish to pass, with no abrupt transition, from the bacteriology of plague to the localities of it. Before I started on my recent expedition, I spent several months in getting up the Gazetteers of the districts which I meant to visit, partly to become acquainted with a strange country, and partly to note any facts as to population, poverty, kind of soil, height of ground-water, canal irrigation, rainfall, or the like, which might throw light upon the incidence of plague upon some localities rather than on others. There was probably some reason why the villages of Lower Bengal should have escaped plague absolutely, while those of Behar have had several bad seasons of it, or why the districts of Oudh should have had so much less plague than those of the Agra province, or why the Punjab districts of Hoshiarpur and Gurdaspur have each lost 80,000 by it, but the district of Kangra none, although it has an incessant traffic with them by the old and new Dharmsala roads. But the contrast which seemed, on paper, to be the best worth investigating was that between the Bombay coast districts of Kolaba and Ratnagiri, and the districts across the Ghâts from Satara to Dharwar.

Plague-free Villages of the Konkan.

Take for comparison the district of Ratnagiri and the adjoining district of Satara. The coast district might seem to be in some respects the more liable of the two: it has a denser population; there is a constant traffic of people between it and Bombay city (which is said to contain a hundred thousand natives of Ratnagiri, working-class and middle-class), and it is as much an agricultural district as Satara, with about the same number of village communities and one-third more houses per square mile. Again, in matter of fact, plague has been introduced into the numerous small harbours along the coast dozens of times. But it has never taken hold of the villages, and has been so little indigenous in the coast places that the annual average of deaths for the whole district from first to last has been only 400, while that of Satara for the last four years has been nearly 30,000.

PLAGUE IN TWO ADJOINING DISTRICTS.

1905	190	26,275

Clearly there is something in the Ratnagiri villages unfavourable to plague, and something in the Satara villages peculiarly favourable to it. I have visited both, and shall give briefly what I believe to be the relevant points of difference. The Konkan is a rocky region. Looking down upon it, in that magnificent view from one of the "points" of Mahableshwar, one might take it to be a great barren land of red rock; but after descending some miles by the zig-zag mountain road, one comes to patches of cultivation and to scattered hamlets, and at the end of five-and-twenty miles to a large village surrounded by cultivated fields.

The map of the district shows that there are many such villages hidden in the foldings of the hills, and built usually along a stream. My notes relate to a village on the Savitri river, nine miles from the creek of the sea in which it ends. Everything is built of stone. There is an extensive ghât of dressed stone with steps down to a pool of the river. Facing the ghât is the village bazaar, the roadway paved with stone, the houses of one, two or three storeys with stone walls and tiled roofs, raised some four or five feet above the road on plinths of dressed stone, and sometimes with stone steps below the plinths; the houses of the bazaar in a continuous row with doors close together, but the rest of the village more dispersed along the main road and side roads, at one point forming a hamlet, while another part of the village is in scattered houses across the river. The ground-floor rooms are as dark as they usually are in India, with a fire burning on the floor at the far end; the cattle are usually in the house, or in a verandah, but sometimes in a shed of the small compound.

So far as concerned the want of light and air, and the keeping of cattle indoors, these Konkan village houses did not seem to be worse or better than elsewhere. Their masonry construction, their high plinths, and paved roadways, were proper to a region where stone is easily got, and where the heavy monsoon rains — 100 inches average in the year — make durable structure necessary. The other distinctive character of the Konkan villages is the more open order of their houses and small homesteads, which may extend a mile or more

FIG. 2.

VILLAGES OF RATNAGIRI.

along one or both sides of a stream, some villages having only one long, paved street with a row of houses on either side, like many of our own villages. This peculiarity of the Konkan villages can be seen everywhere upon the large-scale maps of the Kolaba and Ratnagiri districts (Fig. 2). On the scale of one inch to the mile, it is possible to show the extent of the village site more accurately than by the conventional dot or small circle of ordinary maps. This lantern slide shows a bit of Ratnagiri district around the head of one of the numerous creeks which run up twenty miles from the sea. It will be observed that the small squares, or rhombs, or other geometrical figures, by which cartographers indicate homesteads or clusters of houses, are peppered all over the surface, so that the houses of one village along a stream almost join on to those of the village above it or below it. Towards the southern end of the district the villages break up definitely into scattered hamlets.

What has been said of Ratnagiri is true equally of the State of Sawantwari adjoining it, which has had only five plague deaths several years ago, besides some fifty deaths among fugitives from neighbouring plague districts. Also the Portuguese territory of Goa, with a far denser country population than any of the British districts to the east of the Ghâts, but scattered in innumerable small clusters of houses or bamboo huts beside their gardens and fruit groves, is reported to have had no plague, although it is in constant communication with Bombay by sea, and with Dharwar and Belgaum by hill roads and the railway.

Plague-stricken Villages East of the Ghats.

Let us now leave this populous coast region, happily free from plague, or almost free, and cross the Ghâts to the eastward. The easiest of the mountain roads is the one that ascends from the coast to the hill station of Mahableshwar, and descends on the eastern side to the Southern Maratha Railway at Wathar, a distance of seventy miles. An hour or two below Mahableshwar one comes in sight of an altogether different kind of country, and a different type of village from those west of the Ghâts. First, there is the upper basin of the Krishna river, with gigantic precipitous sides of red rock and a perfectly flat bottom, shaped liked one of those oval bath tubs that are in common use in India. This lies in the district of Satara and *taluka* of Wai, which was full of plague last cold weather, some of the plague villages being in sight on the flat plain below the carriage road. After passing through the plague-stricken town of Wai, the road continues due east over characteristic Deccan country, which is shown in this lantern slide extracted from the survey map one inch to the mile (Fig. 3). It will be seen that the villages are now large compact squares, at intervals of several miles on a flat ground absolutely bare of intermediate houses or hamlets. In this small piece of map are included villages whose names recur several years in the plague returns. I shall not give particulars of any of these Satara villages, as I have others from districts farther south. But the type is the same in all

Fig. 3.

Villages of Satara.

those black-soil valleys of the Deccan, watered by the Krishna and its numerous affluents. What Sir Thomas More said of the towns of his mediæval Utopia may be said of them:—"Whoso knoweth one of them knoweth them all, they be all so like one to another, as far forth as the nature of the place permitteth." They are all mud villages enclosed within a ring fence of bushes, sometimes with gates and remains of a wall. Many of them are large, with populations up to 4,000 or over, comparatively few of those that recur in the plague lists having their population, as given

Deaths from Plague in Seven Villages near Hubli, from 1898 to 1904.

Pop. in 1891.	Village.	1898.	1899.	1900.	1901.	1902.	1903.	1904.	Total.

on the margin, under four figures. In the first season of plague amongst them, 1898, some villages lost more than a fourth part of their inhabitants in two or three months. Thus the village of Shelwadi, *taluka* of Navalgund, district of Dharwar, with a population of 4,222, had 1,126 plague deaths in eight weeks of October, November, and December. In Table I. (p. 815) I have taken out the figures for a cluster of seven villages in the *taluka* of Hubli, to show the severity of their first plague season, and the extent to which they have suffered in subsequent years.

Two villages which I visited, one twelve miles from Belgaum, the other seven miles from Dharwar, will serve as samples of the large villages in the black-soil basin of the Krishna, each of them having had five epidemics in the course of seven years.

A Belgaum Village.

The Belgaum village was considered a rich one, the bulk of the cultivators being prosperous Lingayats. The population in 1891 had been 4,586, it had an area of 2,600 acres, and it was the cattle-market for the extensive pastures on the hills and downs to the north-west. The 800 houses of the village covered 64 acres, about 600 of them occupied by Lingayats and other castes of Hindus, 200 by Mohammedan butchers and cattle-dealers in a separate quarter. It was enclosed by a ring of bushes, outside which was the invariable mud-hole or so-called tank, with the Hindu burning-ghât and the Mohammedan burial-place on its high bank. The houses stood upon a series of slight elevations and declivities, in fairly wide streets or lanes; they were close together in rows, but there was no extreme congestion. They were nearly all built of mud upon earthen foundations; but some were raised a foot or two on stone plinths, and had a few courses of stone in their walls above the plinths, the stone being procurable from a quarry in a hill three miles distant. As it was the dry season, there was much dust everywhere, and a general look of sordidness, unrelieved by a single amenity excepting an occasional carved doorway and two or three verandahs. Some of the houses had been rebuilt within a few years, one last year, on the old foundations. Some had considerable back yards, very ill kept, but most had no curtilage whatever. Yet in a perambulation of the village site, one met with nothing strikingly offensive to sight or smell.

There had been 147 deaths from plague from August to October, but no new cases for six weeks, and the only evidence of the recent visitation was a number of padlocked doors. This outbreak was the fifth since 1898, and the slightest hitherto. I have compiled from the records the following Table showing the whole history of plague in this village :—

Five Outbreaks of Plague in a Village near Belgaum. (Population 4,586.)

Year.	Worst Months.	Plague Deaths.
1898	June-August	375
1899	August, September	741
1900	—	—
1901	July, August	336
1902	September, October	225
1903	—	—
1904	August, September	147
	Total	1824

The enormous loss of life in 1899, over seven hundred, was felt in the census of 1901, which showed a great reduction from that of 1891, and the aggregate loss of two-fifths of the population in seven years must have left a good many houses empty. I examined only two of these, in which there had been deaths a few weeks before. They were both old and crumbling, built of sheer mud, without plinths, standing side to side on a slight declivity of the main street. Each consisted of a single square room, without window or back door, with an oil-mill occupying the centre of the worn earthen floor, the occupants of both having been oilmen. The party wall between them was of mud, only six or seven feet high and crumbling at the top, so that the houses were open to each other across the whole pitch of the begrimed roof. Plague deaths had occurred in both, and in one of them five had died out of a family of six. There were several other padlocked doors on the opposite side of the street, and at intervals in the rows of houses elsewhere. Most of the houses, I was told, had been visited in one or other of the five epidemics, those which escaped in one season being invaded in another; whilst some houses had had the infection in them time after time.

While the infection had crept about to all parts of this village site, it was the unanimous opinion that it always began in a certain quarter, the high ground on the northern side, next to the high road, which was the

particular quarter of the Mohammedan butchers and cattle-dealers. The Lingayat cultivators had a bitter grievance against their Mussulman neighbours, which they tried to interest me in, having mistaken me for a person of authority. Slaughtering of cattle, sheep and goats, curing of meat for the Bombay market, dressing of hides, and the like, were the chief industry of that quarter of the village. There was no regular slaughter-house, but each householder used his house or the space before or behind it, for killing in, the flayed carcases and skins being in evidence as one walked past; and of course the whole soil of this elevated corner of the village was saturated with the blood and offal of many years and swarmed with rats, as shambles always do. A year or two before, the sanitary inspector from Belgaum, a native official of the third rank, had made a report upon the nuisance, recommending that the Mohammedans should be removed to a new site outside the village, which could have been found for them with the greatest ease not far off; but the Commissioner had not moved in the matter, and the anger of the Lingayat farmers was unappeased.

A Dharwar Village.

I shall take next a somewhat different sample of these villages, which also has had five epidemics of plague in the last seven years, but not so severe, and curiously enough always three or four months later in the season, as this Table shows:—

Five Outbreaks of Plague in a Village near Dharwar. (Population 4,661.)

Year.	Worst Months.	Plague Deaths.
1898	Dec.	101
1899	—	—
1900–1.. ..	Jan., Feb.	229
1901–2.. ..	—	—
1902–3.. ..	Jan , Feb.	175
1903–4.. ..	March	185
1904–5.. ..	Jan.	32
		722

This village was a purely agricultural one, with no cattle trade; which is the common type on the rich black plain, or *desh*, extending eastwards from Dharwar. The road all the way from the city passed through an unbroken expanse of wheat, jowar, and cotton, many of the wheat fields being of 20 acres. The area of the village in question was about 2,000 acres, but much of it was in the hands of a few large farmers. The patel of the village, a headman in stature as well as in name, farmed 100 acres, another resident farmed 200, and several who were resident in Dharwar city were also large owners and occupiers. About a fourth part of the villagers were labourers who held no land, many having lost it by mortgaging to the wealthier villagers, or to pleaders in Dharwar, who had thus acquired their large farms. The village had once been defended by a wall, and still retained two gates. Although it contained a number of well-to-do farmers, it did not contain a single *pakka* dwelling-house. The houses were all of mud, many of them raised about a foot above the road on plinths of stone, which was got from a hill overlooking the village on the north. There was only one masonry structure —a variegated marble hall with open top galleries, for public meetings, which had been built recently by subscription. The streets or lanes were fairly wide, unpaved, and deep in dust. Few of the houses had verandahs, and they were all equally common or mean. The usual ground plan was three rooms, one behind the other, with a back door opposite to the street door, but without windows, the cattle being kept in the apartment next the street. All round the backs of the houses ran a space which was enclosed in places, traversed by not over-clean footpaths, and overgrown with bushes; but in the dry weather it was not notably filthy, and there appeared to be no particular need for what is called village sanitation; at least one did not see where the sanitation was to begin, so long as the streets were unpaved, and the whole village, except the marble hall, built of mud. At the date of my visit in December, the fifth epidemic of plague had only just begun, but it appears from the subsequent printed returns that fourteen died of plague in December and eighteen in January, while a continuance until March was probable, according to precedent.

Plague-villages of the North-West.

Time will not allow me to describe in detail other plague villages, and I regret especially that I must pass over the much better type of village in Gujarat, in which the houses are mostly built of brick (but sometimes repaired with mud), raised on plinths, commodious, and not without traces of taste. Leaving the Bombay Presidency, and coming next to the

North-West, which is now by far the worst seat of plague, the many thousands of villages which have had the infection in them are of a very uniform type. As one goes westwards, the compact fort-like aggregate of mud walls and flat roofs becomes more distinctive, and throughout the whole of the Punjab that is the type. We have left behind the more open and irregular formation of the small Bengali village, with clumps of trees or bushes between the several homesteads, patches of kitchen garden among the trees, and creepers overrunning the verandahs. High pitched tiled roofs succeed, and after these thatched roofs with broad drooping eaves, until at length we come west of Allahabad to the naked mud walls and flat roofs of the North-West, without a single amenity that the eye can rest on, and in many cases without even a tree beside the village well. The interior of these villages is not unlike that which I have already described for districts of the south, but the houses are often huddled together, with narrow winding lanes between the rows, and sometimes in compact blocks, back to back and side to side, with no intervals at all. I shall take an extreme instance from a large and wealthy village of Jullundur. Jullundur is one of the most fortunately situated districts of the Punjab, and its villagers are proverbially well satisfied with their lot in life. They have a soil renowned for its fertility, and they have water so easily reached by wells wherever they may sink them, that they can dispense with irrigation canals, and need not pay two or three rupees an acre for watering their crops. If they are poor it is because the pressure of population is great, being indeed about 600 to the square mile, and the highest in the Punjab; but the signs of poverty, or at all events of distress, are not at all obvious to the passer-by, and the people are of good physique. The district was the first in the Punjab to be infected with plague, and in the last four years it has lost 100,000 by that cause; at the time of my visit, those who were dying were said to be robust men and women in the flower of their age.

A Plague-village of Jullundur.

The particular village which I am about to describe had a past history of plague, but I am unable to give it, as the Punjab Government does not tabulate and print its returns from villages, as the Bombay Government has done from the beginning. Its population was about 3,000, and it had lost about 250 by plague in the months of March and April preceding (1904). The greater number of those deaths had come from a square block of houses (and from one or more like it) which had the most remarkable construction that I saw anywhere in India. It was literally a hive of some thirty or forty mud cells. A narrow passage ran round the square, with doors at intervals in the dead wall. Entering by a door near a corner of the square, one came into a room, which somehow held a cow or bullock as well as the family, and had a hatch-like opening in the flat roof with a ladder to ascend by. On reaching the roof one found that it was a continuous expanse of thirty or forty small squares like those of a chess-board, marked off from each other only by ridges of mud, which one had to step across in walking a distance of some thirty or forty yards to descend by another ladder at the opposite corner. Each of the thirty or forty square roofs had a round hole in the middle, invariably covered by an earthenware cap like an inverted flowerpot. Close to this mud block, separated from it only by the six-foot passage, was a group of ten or fifteen brick houses two and three storeys high, with windows, balconies, and the usual features of the *pakka* houses of towns; this was the only masonry quarter of the village, holding about a twentieth of the population. I could not learn whether its residents had escaped altogether the infection which was so violent in the mud block next to it, but it was certain that most of the plague cases had been in the latter, or in another like it, some cells being pointed out in which as many as four persons had died. Most or all of the apartments were now retenanted, and there had been no sign of a revival of the infection down to the middle of January last. In another village, at the other end of Jullundur district, I mounted the roof of a block of houses in the Mohammedan quarter, thinking to find a continuous expanse like the former; but in that instance there were cattle-pens and one or two alleys in the midst of it.

Plague in the New Villages of the Chenab Colony.

Having been told that the new regulation villages of the Chenab and Jhelum colonies had had plague in them equally with the old Punjab villages, which was not at all what one would have expected in recently occupied sites, I visited both colonies to see how the matter really stood. I found from the printed figures

of 1904, that the district of Jhang, which included fully three-fourths of the Chenab colony (now the Lyallpur district) had had 4,000 deaths from plague, nearly all in April and May, 1904, which was only a tithe of the rate of other Punjab districts equally populous; and that the southern tahsil of Gujranwala, which included the rest of the new Chenab villages, had had far less plague than the three other tahsils, where the villages were old. Still, there had been plague in the new villages, one of those which I visited having had thirty deaths in the month of December, 1903, with a prospect of more if the villagers had not cleared out into the jungle, and another near it, but built two years earlier, before the regulation plan was adopted, having had sixty deaths. There are more than a thousand such new villages in the Chenab colony, which have been built within the last twelve or thirteen years. The colonists are in great part retired sepoys of the Sikh regiments, with their *subadars*, or native officers, as the lumbardars of villages. Sepoys received grants of 18 acres, some officers a square of 28 acres, others two such squares, paying a small land tax, as well as so much per acre for the use of the canal water for irrigating their fields. The land is now nearly all taken up, and is producing heavy crops of wheat, cotton, and sugar, the export of wheat from this district being one of the largest from India, as the railway traffic showed.

The regulation village which I visited, about six miles across country from the railway, was a great improvement in some respects upon the ordinary hugger mugger of an old Punjabi village. It was laid out in regular squares with wide roads between; the compounds were roomy, with the dwelling-houses kept apart from the cattle sheds; a certain elevation had been prescribed for all dwelling-houses, perhaps ten feet or more, just as our own Local Boards have raised the height of all new country cottages. But the Public Works Department had left the colonists a free hand in the matter of building materials, and they had built their villages of sheer mud. In the village I am referring to there was not a single kiln-burnt brick except in the facing of the village well, and, so far as I could see, there were not even sun-dried bricks in the walls of houses. The whole village was a hasty pudding of crude mud walls, some of which were already cracked. When I asked to see some house in which there had been plague I was shown a closed door a few feet behind the chair of state in which I was seated at the cross-roads of the village; it was a small corner house or shop, apparently a single room without a window, in which two cooks had died of plague; the mud wall was cracked in places, and had one or two round-holes in it which looked suspiciously like rat holes. All the new villages of the colony are built of mud, except those few which have the good fortune to be stations on the railway.

Plague in the Old Villages of Shahpur.

The other irrigation colony, between the Chenab and the Jhelum rivers, is now being planted throughout the jungle of Shahpur district, following the lines of the Jhelum Canal. Last year Shahpur had the enormous mortality of 33,000 from plague among 470,000 people, most of it in the time of the wheat harvest. I suppose that some small part of it occurred in the new villages, but if the instances which I saw were fair samples, most of it must have come from old villages, of which there are many within the valley of the Jhelum, depending, as of old, on wells and on the rainfall for their harvests. The three villages which I saw at close quarters were within a few miles of each other, all raised conspicuously above the dead level of the plain on conical mounds of black earth. Their mud houses covered the sides and summit of these mounds, which were doubtless formed by the *débris* of former villages upon the same site, and may have been growing by accretions of rubbish ever since the time when Alexander overthrew Porus on a battlefield not many miles distant. They looked the filthiest and most dilapidated villages that I had seen anywhere, and were credibly said to be swarming with rats. Each of them had lost about a fourth part of the population by plague the year before.

Before I leave the villages, which have nine-tenths of all the practical interest for plague, I will give a few minutes to two questions about them. First, is there any real need or excuse for all this mud building? and, secondly, are the large, compact, fort-like villages necessary and likely to continue?

Mud Walls.

First, as to the almost universal mud walls and roofs in the North-West. In the Punjab districts which suffer the extremes of heat and cold, the excuse is made that mud walls are the coolest in the hot weather and the warmest in the cold. But the more general explana-

tion is undoubtedly the ease and small cost with which mud houses can be run up. On that point I may be permitted to quote a few sentences by the late Mr. Frederick Growse, who gave much attention to Indian architecture, and did much to revive the native building arts in his Collectorate of Bulandshar :—

Replying to a circular of the year 1888 on the question of village sanitation, he wrote :—

"Under such supervision, an ordinary Indian village would in the course of a few years be less repulsive in appearance than it is at present, but I doubt whether the death-returns would be materially reduced. . . . The real scourge of the country is fever. This is felt all the year round, and will continue to be so until the people adopt a more rational style of house-building. At present the ordinary mode of procedure is to dig a pit, and with the clay extracted from it to raise a wall on its margin and roof it over for a habitation, the floor either remaining several feet below the surface of the ground outside, or being partly filled up with the first rubbish that comes to hand. . . . In no country, however barbarous, is such a style of building in vogue. It has been adopted in these provinces on account of the tenacity of the ordinary clay soil, which thus lends itself readily to the purpose. But if in other countries, where poverty is as much felt as in India, building materials have invariably to be brought from a distance, the same necessity should be recognised here."

Again, referring to the district of Fatehpur, he says :—

"Thus, for want of skilled labour, the villages are all exceptionally mean-looking collections of mud hovels; and the towns which sprang up under the Oudh Nawabs are all in decay. . . . . . . If the standard of living is low, it is more so from habit than from absolute lack of means; large sums are yearly expended on the only public works which a Hindu ordinarily recognises, namely, temples and bathing-tanks."

The alluvium of the whole North-West makes a sufficiently tenacious clay, and the black soil of the Deccan valleys is even more sticky. The former can easily be burnt into bricks, while there is always red soil suited for brick-making, or a stone quarry, at no great distance from the black cotton soil. When I asked the lumbardar of one of the new villages in the Chenab colony, "Why do you not have *pakka* houses?" he answered, "We are very poor men." But, as Mr. Growse said, the poor standard of living is more from habit than absolute lack of means; other countries, where poverty is as much felt as in India (and more felt than in the Chenab colony), employ village masons and carpenters, and they have shown their progress in well-being first of all in the improved housing of the peasantry. This has been the recognised test in Ireland in the last fifty years, and in Scotland the great advance in the latter part of the eighteenth century was shown in nothing so much as the disappearance of such "auld clay biggins" as Burns was born in. Yet in India mud villages have entered on a new lease, under the auspices of the Public Works Department.

Sanitary Advantages of Hamlets.

As to the large, compact, fort-like villages which are peculiarly the seats of plague infection. It passes as an axiom in India that small villages and hamlets may be almost left to take care of themselves in a sanitary respect. The axiom is embodied in the Government Revenue Handbook, and it recurs time after time in the replies to two circulars on village sanitation issued in 1888 and 1893. What was thus obvious in times of cholera is not less obvious in the present time of plague. The advantages of hamlets are even more marked in the latter, for the Bheels of Western Khandesh, who were among the chief victims of cholera in the last famine, are said never to have plague in their rude hamlets or moveable camps, although the infection has been disastrous in the settled villages of Eastern Khandesh. The same escape from plague of small and moveable hamlets was remarked by Colvill in his tour through the plague districts of Mesopotamia in 1874. The trouble always and everywhere has been from crowded sites too long inhabited without drainage. The more compact the site, or the greater the congestion of houses upon it, the more will the soil be filled with organic impurities. It is well known that soil has the property of breaking up organic matters by oxidation and nitrification, that it filters off and retains organic substances suspended or dissolved in water, arrests the action of ferments, and retains bacteria in its upper layers. But if the upper stratum be saturated with organic matters beyond the power of the soil to enter into combination with them, each new accretion sinks down more or less slowly to the deeper layers unchanged, there to undergo putrefaction or reduction by ferments, so that beyond a certain point the self-cleansing action of the soil breaks down. The limit of endurance is passed constantly in old inhabited sites, whereas in fields pastured by cattle or sheep, or manured for cropping, the

wholesome chemistry of the soil goes on from season to season without check. That the infection of plague resides in the ground is now accepted by every practical man in India who has been on plague duty, and is perceived intuitively by the people themselves.

Centre of Plague in Oudh.

Such being the correct scientific theory of plague, one may find in it one reason why those parts of India which have the rural population least congested in particular spots should have had little plague or none. I have given the instance of the Konkan somewhat fully, and have a few remarks to make about Oudh. The Oudh landscape is always pleasing. There are other provinces, such as Gujarat, which may dispute with Oudh the title to be the Garden of India, but it is certainly the garden of the north-western plains. It is the province of hamlets or small villages, and of a resident nobility and gentry. Plague has not been absent from Oudh; for, two or three of the districts in the south and east, along the Ganges, have had large mortalities. As the Government of the United Provinces does not print full details of the villages infected with plague, one has to find out by personal inquiry, and I was advised to choose Fyzabad as a characteristic part of Oudh. In the week before, that district had returned 110 deaths from plague; and the question was, What kind of villages did these come from? One of the four *tahsils* of the district had to be taken as a sample, and the Fyzabad *tahsil* was the most convenient. It appeared that a full half of all the plague deaths in it were being returned by one village, ten miles from the city, which I went to see accompanied by the tahsildar. It was a large market village of over 4,000 people and 700 houses, with very little agriculture (chiefly sugar-cane) and much cattle trade, more than half the population being Mohammedans. The Sanitary Inspection Book, one of those ordered by Government circular of 1893 to be kept in large villages, contained at various dates severe strictures upon the squalid condition especially of two of its nine *mahallas*, and remarks on the slaughtering of cattle by certain butchers in their houses, and on the common practice of killing sheep and goats in dwelling-houses. There had been plague in it two years ago, and at the time of our visit one whole quarter of the village was evacuated, owing to dead rats having been found and to plague cases thereafter. This quarter consisted of the same two *mahallas* which had been censured as specially squalid long before plague appeared. There had been 65 deaths so far, and two fresh cases that day. The other chief centre of plague in the *tahsil* was also a large market village, with a population chiefly Mohammedan. A few other villages had been returning plague deaths, but none of them more than ten in all, and it did not appear that any of the hamlets had plague. The largest purely agricultural village, with 1,600 people and 2,400 acres, of which fully half were cultivated, was distributed in ten hamlets, and had no plague. On an average the Oudh districts have had hardly more than a third as much plague per head of population as the districts of the Agra province, a ratio which is inversely as the number of hamlets and is most probably dependent thereon.

Hamlets v. Large Villages.

Are there any reasons why the more wholesome kind of country life which is found in Oudh should not be extended to other parts of the North-West? I quote a few sentences to show that the plan or type of large compact villages is neither ancient nor immovably fixed even now. In the "Gazetteer" of Muzaffarnagar it is stated:—

"When Sikh, Rohilla, Gujar, and Marhatta together, or in turn, ravaged the district, no small community could exist, and the settlers fell back on the strong villages from which they had gone forth. After the final pacification in 1805, colonies were again sent out, but so gradually that the beginning of not a few flourishing villages is still remembered."

Again, as to the tendency to return to hamlets, and their sanitary advantages, Mr. Adams, formerly collector of Benares, wrote in 1888:—

"The Sanitary Commissioner has not, I think, taken note of the manner in which, in many parts of these provinces, the villages are splitting up. The villagers in old days clustered together for mutual protection, but now they find they can live close to their fields, and hamlets have sprung up all over the country."

But they are not springing up in the black soil valleys of the Deccan, nor in the Punjab, except in cases of feud between one part of a village and another; and it will appear from what I am about to read, from the pen of Mr. Alan Cadell, that there are reasons why the large villages should remain large:—

"The crowding of the population into large villages," he writes, "is to a certain extent disadvantageous, but the power which the large cultivat-

ing communities have acquired from their numbers and their wealth is of great service to them in resisting the encroachments of the landlords; and the people must feel that they would lose in unity and defensive power if they were scattered over several hamlets instead of being collected together in the old ancestral village. The fact, too, that nearly all the best land is held by occupancy tenants, whose fields are situated all over two and even three estates, makes it still more unlikely that any large number of tenants will leave their present dwellings, for to do so would, while bringing them nearer some fields, take them away farther than before from others, and to effect changes of hereditary fields is always difficult and generally impossible."

Plague in the Cities.

The circumstances of Bombay are so special, if not unique, that it would take a whole hour to discuss them. Therefore I shall not begin upon them, however inviting the theme. Poona, infected from Bombay, has had severe plague every season for nine years, and more of it per head of population than Bombay itself; the sanitary problem is complex there also, and cannot even be stated in a sentence or two. Karachi and Calcutta I did not visit. I will come to Benares, as a good sample of the North-Western cities.

Benares.

The *mahallas* or wards into which Benares is divided fall into two classes—the *pakka*, or masonry mahals, and the *kaccha*, or mud mahals. The separation of the two is sharper, I believe, than in any other Indian city, and will be readily understood from the situation of the masonry mahals. They are that famous range of houses, temples, and terraces which crowns the high bank of the Ganges for a space of nearly two miles. Some fifty or sixty thousand of the population are housed there, and twice as many more in the *kaccha* or mud-built suburbs which extend back from the river-side quarter over a radius of two or three miles. These *kaccha* mahals, however, are not all equally mean in construction; for example, the road, three miles long, which runs from near the cantonment to the railway-bridge over the Ganges, is lined on both sides all the way with houses or shops of brick raised on plinths. The *pakka* mahals along the river are built of stone, which had been brought some twenty miles down the Ganges, from the extensive quarries near Mirzapur. There are no carriage-ways through this region, but only a maze of narrow alleys, with houses on either hand three or four storeys high, and innumerable temples—a perfect rabbit-warren, like the Closes of the High Street, Canongate, and Cowgate of Old Edinburgh. What strikes one most in the not unexciting passage through this maze is the solidity and durability of the structure everywhere. The walls are of stone, the courtyards and floors are paved with stone, the alleys are laid crosswise with long slabs of stone, which form at the same time the roofs of a network of sewers. In this dense mass of humanity, constantly mixing with pilgrims from all parts of India, there has been hardly any plague. I make this statement on the authority of the police inspector who accompanied me, as well as of the Collector, Mr. Radice, who wrote as follows:—"In the five years we have had plague (this is the fifth) the *pakka* mahals have been almost entirely free;" and in the sketch plan showing the incidence of the infection on the several quarters of the city, which he was good enough to make for me, he has marked only one small spot in the riverside quarter, the Gaighat, which had some plague in 1903. On the other hand, the mud-built suburbs and the villages to the west of the city, have had much plague; for example, this year a maximum of nearly 400 deaths in a week in March. In driving through them one could tell at a glance where the plague was likely to have been; thus, on the way from the cantonment to the city, a certain dip in the road is lined on both sides with mud houses of exceptionally mean appearance, which is found, on reference to the plan, to be the Tiliabagh, marked as having had plague "every year."

Cities of the North-West.

In all the other cities of the North-West, which have had much plague, there are extensive quarters of mud-built houses—in Allahabad, Cawnpore, Agra, Lucknow, Bareilly. In Lucknow, beautified as it is with palaces and fine houses, the relative extent of the *kaccha* mahals seemed to be enormous, and the mud walls of so dusty and friable a kind that the heavy rain of December had been breaking them down. Lucknow this year has had up to 480 plague-deaths in a week, a ratio higher than Bombay. I shall give a single illustration of plague in Agra. One of the patients in the plague hospital, a convalescent, was a little girl, the sole survivor of a plague-stricken family of nine. On proceeding with the assistant medical officer to see the house where this tragedy had happened, we found it

to be a dilapidated and abandoned mud hut, one of a compact group of three standing at the road side on the edge of a small pit from which the earth to build them had doubtless been dug.

The three large cities of the Punjab, Delhi, Amritsar and Lahore, have had remarkably little plague. Delhi, which is situated in a stony region, appeared to be nearly all *pakka* built, with the exception of a few lanes around a celebrated Black Mosque of the fourteenth century; and even the villages round Delhi are built of a kind of conglomerate of stone and clay. Amritsar also is a well-built brick city, and in Lahore there are no such extensive quarters of mud-built houses as in Allahabad and Lucknow. The smaller towns and market villages have in some instances furnished a large part of all the plague deaths credited to a rural area. I was told by the Civil Surgeon at Ghazipur that the largest totals in his district this year were coming in from certain towns or market centres which had a considerable Mohammedan population; and in the district of Muttra I saw for myself two such market towns with much plague in them, one of them, population of 9,000, having had 400 deaths in the four weeks preceding, and a maximum of 25 the day before, while the other, with a population of 6,000, had 19 new cases reported that morning. It is the melancholy fate of those old country towns of the Mohammedan period, originally well built, with brick houses and paved streets, and in some cases with fine sarais or forts, to have fallen into decay of trade and dilapidation of buildings, the houses often "*pakka* without but *kaccha* within," as explained to me of an old two-storied brick house at a village near Benares, in which the rats had been found dead and, two or three weeks after, the whole of the inmates, to the number of eighteen, had died.

Means of Avoiding Plague : Evacuation.

According to everyone's belief and experience in India there is only one thing to be done when plague appears in a place, or the rats begin to fall, namely, to clear out, or at all events, to avoid spending the night there. Hence the strange spectacle every evening about sunset, in the city of Bijapur, of the whole population, save the inmates of half-a-dozen bungalows, to the number of some 20,000, quitting the bazaars, workshops and offices, and making their way outside the walls to a large camp on the downs around the railway station. This phenomenon is the more suggestive at Bijapur, as the city was deserted once before, 200 years ago, and most probably for the same reason as now, namely, plague, and continued to be in great part deserted until it was made the administrative head-quarters of the district about 30 years ago. Also in the country round Bijapur the people have learned the lesson of evacuation very thoroughly. I went through an old fortified village of 3,000 people five miles to the west of it, without finding a living creature: the streets were deserted, and the doors of all the houses padlocked, the whole of the inhabitants being in camp near their fields about a quarter of a mile away. They had taken alarm from the number of dead rats found, and the deaths of 36 persons in October, November, and December, and from the recollection of their first plague epidemic two years before, when 171 died in the village. At Bijapur city, I was told by a high native official that, if the infection became active another year, the temporary camp round the railway station would become a permanent residential suburb, so that the area within the walls would be deserted for the second time in its history. This evacuation is at the people's own initiative and at their own expense, which many of them can ill afford. The same thing was going on at Belgaum, where several thousands went out to camp in the evening and returned to their work in the bazaars and offices in the morning.

At Dharwar a small beginning had been made towards permanent evacuation. The Government had given a piece of vacant ground to the municipality, which had sold it by auction in lots at a very low price, and a new street of some forty houses, called Gibb-street, after the Collector, had been run up. At Poona 7,000 or more were in camp along the sides of suburban roads, or on the various maidans of the city. At Bombay there were three large health camps along the seaward side of the island as far north as Mahim. In a group of villages of the Baroda State near Naosari, the cultivators had built lofty and commodious huts near their wells and fields, to which they had removed their bedsteads, chests, and other furniture, and in which they and their children and their bullocks were not unhappy. The weather after the rains is so fine throughout the Bombay Presidency that there is no hardship whatever in camping out.

It is otherwise in the greater part of the plague-season of the North-West, of which I

shall give a single instance from the Punjab. I went one day with the medical officer on plague duty to a group of villages twelve or fourteen miles from Jullundur. At one of these, a small village of some two hundred people, there had been many deaths from plague two years before, and on the day of our visit there were more persons lying sick or recovering in their houses than I had seen anywhere in so small a space except in the hospital at Bombay. After we had gone round the village, a palaver was held with about a dozen of the men and youths, who stood in a semicircle near the village well, the women drawing water all the while. Their spokesman was a sturdy little Jat who knew his mind, spoke to the point, and bore himself with the aplomb of a man of affairs. They had been asked in advance to consider whether they would not submit to inoculation, and had decided so peremptorily in the negative that the matter was not so much as mentioned again. The only question discussed was evacuation. The spokesman pointed out various practical difficulties in the way of a general camping out, to which Captain Bradley replied; and at length it came to this, that the whole village might remove to a camp on a certain piece of waste ground within sight of where we stood, if some help were forthcoming for the poorer villagers; it was all a question of expense, and as I was again mistaken for the Commissioner, I was looked at in a significant way as we took our leave. But to show how many are the difficulties in the Punjab, next day a storm of wind and rain broke, which lasted thirty-six hours, and was followed by two or three weeks of intense cold. Camping out was of course impossible, and the effects of the cold snap were seen in the abrupt rise of the plague figures about a fortnight after from all parts of the Punjab and the United Provinces.

Scientific Theory of Evacuation.

Evacuation of plague-infected houses or village sites had been adopted by the people themselves, without any scientific advice, before the present plague; for example, by the hillmen in Kumaun, and by the Marwaris, who, as White reported in 1836, "instantly quitted a house on seeing a dead rat." The rats themselves, although in India they are the symbols of sagacity, are usually surprised by the underground venom, and are often seen trying to escape in a state of delirium. A scientific explanation of the common practice may be found, first, by including plague fully and frankly among the soil poisons, as I did in my "History of Epidemics in Britain," fourteen years ago, and, secondly, by applying to it the laws of soil-infection which have been worked out by Pettenkofer and his school. An infection of the soil makes itself felt most inside dwelling-houses, and most of all overnight, because there is a natural movement of the ground-air towards the walled space. This was shown by the fact that an escape of gas from a main in the street would travel horizontally through the pores of the ground towards the house opposite, and be sucked up into it, sometimes to the danger of the inmates. von Fodor observed the stratum of air next the floor of an unoccupied cellar at Buda Pesth day and night for a whole year, and found that it always contained more carbonic acid than the ground-air outside, having attracted it from the soil around. In disused cellars, vaults, or covered wells, the accumulation of carbonic acid is sometimes so great as to asphyxiate those who enter them first. One reason for the ground-air streaming to and rising through the basement or floor of a house is that the ground beneath is drier and more permeable, affording a free upward passage unless there be a concrete foundation, or a masonry plinth, or stone paving. Another reason is, that the air inside a house is warmer and lighter, so that it yields to the pressure of colder and heavier air outside and is thrown into an ascending current. The penetration of the house by ground-air is a peculiar risk in India for several reasons. Where the walls are of mud, as they are in the great majority of plague-villages, and have no masonry plinth to rest upon, their porous substance is really a part of the soil, so that the inmates have the ground-air not only rising from the floor but carried up in the walls as if in a ventilating shaft. A dwelling-house warmed all day by the sun, and by the fire kept up for cooking, becomes like an exhausted receiver for the ground-air to rise into. If you visit the old chawls at Bombay, in which there has been so much plague, you will find the narrow dark rooms on the ground floor to be heated like an oven even at eight in the morning.

The intuitive perceptions of the people correspond with the scientific theory of a soil-poison. They know that the chief risk of taking plague is from spending the night in an infected place; and generally that they incur the greatest risk when confined most to the dwelling-houses by cold, domestic duties,

or other cause. One very important thing I must pass over for want of time, namely, the injurious effect of a high level of the ground water, and of its seasonal fluctuations, in a filth-sodden soil. In the new chawls at Bombay, built by the Improvement Trust, nothing seemed to me to promise more for the future health than the solid masonry of the foundations, floors and passages. The advantages of concrete foundations have been proved often in similar circumstances.

PROBABLE FUTURE OF PLAGUE IN INDIA.

I come lastly to the question—Is there anything to be learned as to its probable duration from historical precedents and from its own course during nine years? One was sometimes asked whether the natural time for plague in India to last was not seven or eight years. The origin of the idea is what is recorded of two former plagues in India—one in the reign of the Emperor Jehangir, 1616, of which it is said that "it continued to devastate the country for eight years;" the other in the reign of Aurungzeb, 1688, which "lasted seven or eight years." Each of these epidemics of bubonic plague is authenticated twice over by good contemporary authorities, along with some interesting particulars which I have no time to quote. The earlier of the two began in the Punjab at Lahore, and "destroyed many villages and parganas;" the later, seventy years after, was felt most in October and November, 1688, in the city of Bijapur, which Aurungzeb had just captured, and in which his army was encamped, including 15,000 cavalry; but it is said to have lasted seven or eight years and to have extended over the Deccan and as far as Ahmedabad and Surat. The next outbreak in India fell to be described by three British writers; it happened in Cutch and Kathiawar from 1815 to 1821, in peculiar circumstances of aggravation within walled towns, arising out of famine and the mode of collecting the tribute from the recalcitrant petty chieftains of those territories by the army of the Gaekwar; and it came to an end almost coincidently with the new order of things in 1821. The only other epidemic before the present was also a limited one, in Marwar, especially in the town of Pali, which lasted from 1836 to 1839, and may have been a revival of plague which is said to have been indigenous in Marwar "from a remote period."

Turning from those Indian precedents to the much more continuous and extensive plagues of Europe, we find an uninterrupted history in one country or another, and in one city or another, for more than three hundred years—from the year 1347 to the latter half of the seventeenth century, when the infection disappeared almost simultaneously from all the countries of Western Europe. The chief difference between the European plague-period and the one which is now running its course in India is that the former did not involve the villages, but only the towns, except in its first great wave, from 1347 to 1350, which swamped country and town alike with an almost unheard-of mortality, and excepting, perhaps, two or three general but minor revivals at intervals in the latter half of the fourteenth century; for the rest, it continued an infection of the towns, and in these it commonly broke out at long intervals, twenty or forty years, excepting in such capitals as London, where it was seldom dormant for a series of years until it was about to cease altogether.

It is not surprising that plague in India should be chiefly an affair of the villages, because that has been also the experience with cholera. So much was that a village infection that Anglo-Indian writers who were at home when cholera reached this country in 1831 prophesied that it would fall most upon the enormously congested rural population of Ireland. But it spared the Irish villages and hamlets almost absolutely although it attacked the Irish cities severely. European precedents being thus inapplicable to India as to villages, we are thrown back upon the lessons that may be learned from the history of plague in India itself during the last nine years. It is only from the Bombay Presidency that we have data minute enough to be of much use; from which it appears that the huge totals of plague deaths year after year are not so hopeless as they look. When they are analysed—and it is no small labour to analyse them—it is found that the aggregate of each year has been made up by items from somewhat different places. The cities of Bombay, Poona, and Karachi have been steady, but in the mofussil all the districts have not suffered severely in the same year, the *tálukas* within a given district have been affected some one year, some another, and the villages of a given *táluka* have been affected in a kind of rotation. I have shown on the screen the tables of nine villages, which on the whole agree in proving that each village has had one very severe outbreak, usually the first, that there have been years absolutely

clear, and that the subsequent outbreaks have been much less extensive than the original one. It is in the very notion or definition of the word "epidemic" that there shall be intermissions; the word "endemic" means a more steady prevalence from year to year; but in that notion also the steadiness is only in the aggregate of a whole country or province, not in the several counties or parishes of it. It is probable that all the villages of Bombay Presidency by this time have had their worst experience of plague, and that in each village plague has visited all the houses in turn, or as many of them as it is ever likely to visit. The Bombay figures for the season just ended are encouraging. Whether it be owing to the resolute practice of evacuation on the first signs of plague, or because the invasion is subsiding naturally, the returns since January have been only about one-third those of the three or four years preceding for the corresponding weeks. It looks as if the maximum had been reached and passed, both for each locality and in the aggregate of the whole Presidency, and that there is to be a pause. Such pauses occur in all epidemic infections. We account for them by a phrase or formula, that the infection has exhausted all the "susceptible subjects," and we explain the return of the epidemic after an interval of years by the fact that a new generation has grown up which contains more "susceptible subjects."

What can be proved from the admirably full statistics of the Bombay Presidency may be perceived in a way in the Punjab. Thus, in Jullundur in January this year I learned that the average was being kept up to that of former years chiefly by returns from a certain group of villages in the south-west which were having plague in them for the first time. The province as a whole is to have more plague-deaths this year than it has had hitherto; but it would certainly have shown a decrease but for the very large items of three districts in the Delhi Division—Gurgaon, Rohtak, and Hissar—which are having their first severe epidemic. The prognosis for the Punjab should be, that the infection has reached its height and done its worst for the time in the districts first attacked, and that it will soon begin to show a decline in the aggregate, following in the wake of Bombay Presidency.

This is the first year in which the United Provinces and Behar have returned such large totals as we have been accustomed to for several years in Bombay and the Punjab, and as one of them has a population nearly twice as great as these two latter together, it is unsafe to prophecy what heights plague may not reach in them before it begins to decline. In any case, we may reckon with plague domesticated in the soil of tens of thousands of villages, making an endemic area larger than that of cholera was ever estimated to be, and from such an endemic area we may expect future outbreaks at intervals of years, if not from year to year. In England, for 30 or 40 years after the great invasion of plague in 1348, a poet of the time compared the state of sickness to "the rain that raineth where we rest should," to the drip through a leaky roof, a chronic state of discomfort and uneasiness.

The three centuries of plague in European towns came to an end without any conscious effort to check the infection anywhere so far as one knows. The most probable explanation is that the towns had emerged slowly from their mediæval life, which was peculiarly favourable to plague, having thrown down their walls and gates, and gradually shifted the pressure of population to new sites, which, however, were often befouled by the accumulated refuse of the old walled city, and, therefore, apt to retain the infection many years longer. The curious statutes of 32 and 35 Henry VIII., on the decay of practically all the chief towns of England and Wales, bear out that hypothesis, according to the reading of their preamble adopted by Nicholls and Froude. At all events, mediæval limits were outgrown in all the towns of Europe, and, after a transition period of a century or more, plague died out by reason of changed conditions.

India, at the present day, contains more traces of changed sites than any country in the world, and some of these changes have actually occurred under British rule. Sometimes the changes of site have been caused by a river deserting its old channel, and leaving a city too far from the traffic; but there are undoubted instances of sites abandoned owing to chronic sickness. The British cantonments afford instances in the past, and may afford more in the future. Dacca and Berhampore were both condemned, the latter in 1833 after an original outlay of £300,000; they were healthy stations at first, and became sickly by degrees until they were untenable. What has been happening in India from time immemorial, both to town sites and to village sites, through the pressure of events, may be anticipated by a deliberate policy in order to hasten the disappearance of plague. In some of the towns of the Deccan and

Gujarat, new suburbs are actually springing up for the richer class, to avoid the infection. For the villages it is not out of the question that some law might be made to prevent rebuilding on the same foundation when the mud walls crumble, as they do periodically; but of such a law the essential condition would be the helping hand of the State to provide new sites. At one time I held that a progressive change of the village site to a clean soil, along with the break-up of a larger village into several hamlets, would be an effectual if very slow means of getting rid of plague. But after seeing a good many of those dreadful mud villages, I have come to think that it is their miserable structure that is the real reason why the Indian plains are cursed with plague, and that there can be no real cure without a more civilised kind of dwelling, and a great revival of the native building arts as village industries.

DISCUSSION.

The CHAIRMAN said he was sorry he was not in a position to speak from personal knowledge of the plague. Although he had had a great deal to do with the preparations in the Punjab to face the plague when it was then approaching, he left the province before it was actually attacked. The paper just read was most interesting, and the Society was greatly indebted to Dr. Creighton, and, indirectly, to the Leigh Browne Trust, under whose auspices he undertook the journey to India and made his researches. He (the Chairman) gathered that Dr. Creighton did not dispute the position taken up by bacteriologists as to the origin of plague, in other words he did not combat the idea that it was due to a bacillus. But Dr. Creighton did not hope for any great results from the inquiries of bacteriologists; he preferred to study the matter from an outside point of view. For himself, however, he ventured to express the opinion that a complicated and difficult problem of this sort had better be studied from all points of view, and that both Dr. Creighton's researches and the researches of bacteriologists were necessary. He had always been a great advocate for the encouragement and endowment of expert research, and in particular of expert medical research. In his early days he had been for a short time in a medical school, and he knew that no ordinary member of the Indian Medical Service (than whom there was no finer of its kind in the world), who was occupied with the immense labour of his professional work in India could possibly prosecute researches of this sort. No one could do so except a man who devoted his whole life to it. With regard to the Commission which had recently been sent to India under the joint auspices of the Secretary of State, the Lister Institute, and the Royal Society, it would, of course, be rash for anyone to predict success for it. He would say, however, that its objects were not limited in the way Dr. Creighton seemed to suppose. It was not going to confine its investigations to the field of bacteriology, and it would certainly not shut itself up in any laboratory. He might add that so far as its laboratory work was concerned, it was not going to Kassowlie but to Parel. He was sure that special attention would be given to Dr. Creighton's paper by that Commission. As he had already said, it would be unsafe to predict success for the Commission which had been sent out; and, similarly, it would be rash to assume that the conclusions to which Dr. Creighton was inclined to come would be established. Conclusions of that sort could only be based on deductions drawn from immense numbers of instances. Further observations would have to be made, and tabulated by various persons before any positive conclusion could be arrived at. Inasmuch, however, as Dr. Creighton had devoted the best part of his life to subjects of this sort, and as he was a most keen observer, it must be admitted that there was a considerable probability that the conclusions to which we was inclined to come, would turn out to be correct. It might happen that when the results of both his inquiries, and those of the bacteriologists came to be put together, differences of opinion would be found. No doubt it was awkward to have to decide when doctors disagreed; but, on the other hand, it was doubtful whether an immensely complicated problem like the present could be properly thrashed out, and a solution ever arrived at, unless doctors to some extent did disagree.

Lieut.-Colonel S. J. THOMSON, C.I.E., I.M.S., said he had had the pleasure of meeting Dr. Creighton during that gentleman's visit to India, and had done all that lay in his power to put him in the way of obtaining some of the information which the Society had been favoured with that evening. He (Lieut.-Col. Thomson) had had some experience of outbreaks of plague in India, and perhaps somewhat exceptional experience in the matter of *maha mari* in the hills in former times. The latter, which he thought, must be recognised as the same thing as plague in the plains, seemed to be largely, if not entirely, a soil disease. That certainly was the case in some villages where the attack was so severe that the disease could not be stopped until the village was not only quite evacuated, but disinfected, and the roofs burnt. It was often the case that after a year or two plague would recur in such villages, and to such an extent that some had to be eventually entirely abandoned. Up to that time he was inclined to believe that the disease was one entirely of locality, but later, when he came to see the disease on a more extensive scale in the plains, his views had been rather shaken. While conducting operations, he had had an exceptional opportunity of judging the

behaviour of plague during the outbreak at Hardwar. About a mile and a-half away was a second town called Kankhal, and about three miles further on was a large village called Jawalapur. These three towns, which constituted what was called the Hardwar Union, were so isolated naturally, that it was possible so to conduct operations as to cut them off from the rest of the province. A most interesting feature was that Hardwar was largely composed of houses built of masonry, brick, and stone, with cement floors, and in every respect corresponding to the description of houses which he understood Dr. Creighton would like to see all over India. Kankhal was a large pilgrim resort, and it, too, was strongly and permanently built with brick, stone, and cement. The third centre, Jawalapur, however, was quite different in character, being more in the nature of a large village. Indeed, the houses generally were very much of the kind which Dr. Creighton and many others would like to see abolished altogether. He was bound to say, as the result of very careful observation, that he did not see any particular difference in the behaviour of the disease in the *pukka* or cemented towns and its behaviour in Jawalapur. The disease was introduced in one case into a masonry building containing eleven people, but owing to the delicate condition of one of the women it was not deemed prudent to cause the house to be immediately evacuated, as would otherwise have been done. That house was particularly strongly and well built, and isolated, but it happened that before the authorities were able to get into it and deal with the matter, no fewer than nine out of the eleven died of plague. A point which had been rather missed, but which ought to be more particularly borne in mind, was the fact that the houses built of well-constructed masonry were generally occupied by fairly well-to-do persons who lived in somewhat similar conditions to Europeans living in India. Looking at the statistics, at first one was inclined to think that the great immunity of Europeans in India from plague was due to the fact that there was comparatively so few of them, but as time went on he thought it must be recognised that there was something more than that. As a result of his own observations, which were exceptionally large, and extended over a considerable period, he was inclined to put down the immunity of such places to the fact that there was not so much overcrowding in the well-constructed houses, that the people were cleaner, better fed and clothed, and altogether better to do. He might instance the pukka mahals in Benares as such a place. Although there were a few cases there, the area over which the disease spread was small. He was in entire agreement with Dr. Creighton as to the great advantage of voluntary evacuation, and he believed that in this direction lay the eventual solution of the difficulty. That lesson had been learned throughout India. Very little advice, and certainly no compulsion, were now necessary to induce the people to go out. In Oudh, in the Faizabad district, it was particularly easy to arrange that, because the country was thickly wooded. There, for generations the people had been accustomed to keep their cattle and fodder in the little groves outside the villages. Therefore, it was quite easy when an outbreak occurred, to persuade the people to move to those groves and live there, instead of in the villages, until the danger was past. It was no good, however, to use any form of compulsion, for then the disease would be concealed, and it could not possibly be dealt with. As soon as distrust entered the minds of the people, information as to the disease would be withheld by them, and when it was actually discovered by the authorities it would be found so extensive as to be entirely beyond control. Voluntary evacuation, under all the circumstances was, he thought, the best solution of the difficulty.

Professor W. J. SIMPSON said he congratulated Dr. Creighton on his interesting and instructive paper. If he understood Dr. Creighton right, his forecast as regards the behaviour of the epidemic of plague was hopeful so far as the provinces which had been so severely attacked were concerned, and it was devoutly to be hoped that Dr. Creighton's surmise would turn out to be correct. But the measure of comfort thus given was not very great for the decline which was observed in the places attacked appeared to be considered as only a pause or intermission until there was a renewal of susceptible subjects. He gathered from this that Dr. Creighton was no supporter of the doctrine that the plague would soon die out. Those who held this view had from the commencement of the epidemic very successfully, but most unfortunately for the interests of the Indian people, buoyed up the authorities with false hopes, with the result that there had been no continuous and organised effort on a sufficient scale to check the ravages of the disease and prevent its spread into non-infected localities. Plague had been now in India nine years. In the first year there were 30,000 deaths altogether; now they were, in a plague season, 30,000 and 40,000 deaths a week. In 1903 there were 853,000 deaths; in 1904, 1,040,000; and only last week the Secretary of State for India announced in the House of Commons that in January of this year there were 126,000 deaths, in February 126,000, and in March 199,000, so that in the course of the first three months there were nearly half a million deaths from plague. The total loss to India had been 3½ millions, and there was not the slightest sign of it dying out. Last year, when Mr. J. E. O'Conor read his able paper on "The Economics of India," and some of the speakers were inclined to take a very roseate view of the prosperity of India, he (Dr. Simpson) ventured to point out that no country could be said to be in a state of prosperity that was losing annually 1 in 300 of its population from a single disease. Since then he had had the opportunity of extracting from the official records the number of deaths from

plague in the different provinces, and he found, as was shown so well in the map prepared by Dr. Creighton, and contrary to the general impression, that plague was not spread over the whole of India, that many parts of the country still remained to be infected, and that the Punjab suffered the most severely, having lost no fewer than 350,000 of its population in 1904. The province of the Punjab had only a population of 27 millions, one, in fact, which was less than England, and it had lost last year not 1 in 300 of its population but 1 out of every 77 of its inhabitants. It was a province from which many of India's best soldiers were recruited, and it could not be with equanimity that the Government saw the country from which these fine soldiers were obtained being ravaged with plague. This anxiety must be emphasised if the reports which appeared in the newspapers were correct that 200,000 Russian soldiers were concentrated on the Afghan frontier. Dr. Creighton had shown in his paper that even this appalling mortality had been overtopped in some of the districts in which 1 out of every 33 of the population had succumbed to plague, and in some of the villages which had lost more than a fourth of their inhabitants in the course of several years. In dealing with the heavy mortality in some of the villages, Dr. Creighton had contrasted the condition of these villages with those that had escaped, but it was a question whether the villages that had hitherto escaped would retain their immunity. In the pandemics we read of one of the features of the disease was that it attacked one place and left another alone, but when left to itself it seldom forgot the omission and visited, sooner or later, the place which it passed over. With the disease concentrated chiefly in two provinces and with many more parts of the country to spread over, the outlook appeared to be of the gravest character. Few seemed to realise that never before, since the Black Death of 1348, had such an epidemic of plague prevailed in India or outside India. What happened then? According to the Russian records which give a different account of the origin of the Black Death from that given by Dr. Creighton in his splendid work, the "History of Epidemics in Britain," the origin of the Black Death is ascribed to India, from which it spread to southern Central Asia and thence to the Volga and the Don. In that epidemic Europe lost 25 millions of its inhabitants. The plague was, therefore, not only a great calamity for India, threatening to become a still greater calamity if left unchecked, but it might become a great danger to Europe. One of the most remarkable facts connected with this tragedy in India was the comparative lack of organised and sustained efforts adequate to the occasion to deal with the disease. He hoped that he should not be misunderstood; he knew the exceptional difficulties which the Government of India had to face, he knew also the danger of injudicious action, but weighing all these he thought there was abundant cause for dissatisfaction. When he found that half a million people died from plague in the first five months of 1904, and half a million died in less than 3½ months of this year,* and that there was no sign as yet of any extraordinary measures being undertaken to combat the disease and limit expansion, he felt that if this was not a time to speak out he did not know when that occasion could be considered to arise. The only unusual measure that had been taken was the appointment of a scientific Commission; but whether the climate of India was deemed to be too trying, or from some other cause, that Commission was not to study the disease on the spot, but to sit in London, and act as an Advisory Board. The real Commission, consisting of two assistant bacteriologists, were sent out to India to solve the many difficult problems connected with plague, and to over-top and surpass the work of five foreign Commissions, and one English Commission consisting of the highest scientific medical authorities in their respective countries. A Commission such as that now appointed will neither do any harm nor any good. What was wanted in this crisis was something worthy of the great nation that ruled over India and was responsible for its welfare, and this would not be obtained by sending out two assistant bacteriologists to India, where fifty were needed, nor would it be obtained by combating plague by an unorganised and totally inadequate administrative plague department. If Lord Kitchener were asked to meet a powerful invading army without a fairly sized trained service to fight the enemy, and without an intelligence department to keep him well informed no one would be surprised to hear that it was impossible, and yet this was the position in regard to plague. It was more powerful than any invading army. It multiplied in numbers and thus reinforced itself as it went along. It had ways of approach and attack that were not accurately known, It was also an unseen foe; and yet, with all these advantages over an ordinary enemy, it was expected to be met and controlled in a haphazard sort of way, without very much expense, without proper organisation and without strenuous effort, and because the whole thing was a disastrous failure the blame was laid on the people, their customs, and their prejudices. He earnestly hoped that a more enlightened policy would prevail.

Mr. Herbert M. Birdwood, LL.D., C.S.I., said that he had not the advantage possessed by the last two speakers of approaching the subject under discussion as a scientific expert. It would, therefore, savour of presumption on his part if he spoke any words in praise of the paper to which they had all listened with such keen attention. It would savour of something worse—of folly—if he attempted to criticise conclusions drawn by

* The Secretary of State for India has since stated in Parliament that the number of deaths from plague in India for the first four months of 1905 was 687,000.

so high an authority as Dr. Creighton from facts observed by him in his Indian tour—facts which the acquired knowledge and experience of a lifetime had qualified him to observe aright. Still he (Mr. Birdwood) had himself been concerned in administrative work in connection with the first epidemic of plague in Bombay in 1896-97; and facts and incidents had come to his knowledge, or fallen under his own observation, some of which he would like to adduce; and would leave it to Dr. Creighton to say how far any of them corroborated the views expressed by him, or called for explanation in reference to his conclusions. The part of Dr. Creighton's paper which interested him the most was that relating to two districts with which he was himself familiar, the sea-coast district of Ratnagiri, in the Konkan, to the south of Bombay, and the Satara district in the Dekhan, to the east of the Ghâts. The contrast between the comparative immunity from plague of the stone-built villages of Ratnagiri, in which the houses were often stretched out so as to form a long street of detached buildings, and were more or less open to the air, and the prevalent mortality in the compact mud-built villages in Satara, which were often enclosed with a village wall, was very striking. In Bombay, also, it was noticed that people who slept in verandahs of houses, or on cots in the open street, were less liable to attack in the infected quarters of the city than those who slept indoors, in crowded and ill-ventilated rooms. A cold night, which drove large numbers of people indoors, was generally followed by a sharp rise in the daily mortality. In the Himalayan districts, also, in an atmosphere and climate as fine as any in the world, the advantages of living in the open air in villages infected with the form of plague known as *maha mari* which had been described by Dr. Hutcheson, were entirely neutralised by the necessity felt by the inhabitants for crowding together for warmth and shelter in noisome huts. In the fishermen's village of Worli, a few miles out of Bombay, a determined attempt was made to keep the plague away by refusing admission to all strangers. Here, if anywhere, as Mr. Hankin reported, was a chance for a sanitary cordon to be successful. Nevertheless, the plague "broke out suddenly in the village with appalling virulence." Whether the plague germs were air-borne, or earth-borne, or carried by rats, or other ground animals, they were small enough to escape exclusion by the closest cordon, and they found congenial soil in the mud floors of the stuffy, unventilated dwellings of the villagers, most of whom, however, soon encamped in the fields, taking with them their bedding and household utensils. They came back every day to their houses to fetch grain, but, after camping out, they remained free from the disease. The Government of India held that the Worli incident supported the view that the plague is best combated by the evacuation of infected localities; and this seems to be Dr. Creighton's opinion also. In the Great Plague of London, an exactly opposite procedure was adopted. Houses were shut up when the plague appeared in them, and the inmates were not allowed to leave them; and the results were terribly fatal. Nearly 14 per cent. of the population of London died of plague in 1665. In Bombay, the highest estimate of plague mortality during the epidemic of 1896-97 did not exceed 2½ per cent. of the normal population of 820,000, which, however, was greatly reduced for several months by a large exodus of the people. In the second epidemic, the mortality slightly exceeded 3 per cent. of the population. As regards the comparative immunity of Ratnagiri villages from plague, notwithstanding the constant intercourse and traffic by sea between Bombay and the ports of the Konkan, Mr. Birdwood suggested that there might perhaps be some other controlling factors besides the nature of the dwellings in those villages. The average rainfall of the district was stated by Dr. Creighton to be about 100 inches in the year. But the actual rainfall on the verge of the Ghâts was much more. It amounted at Mahableshwar to 280 inches in the year. The effect of this downpour in the four monsoon months must be to scour the surface soil most thoroughly. Indeed, that had been the case in the past to a most lamentable extent. There was a time, in the early years of the past century, when the hills and valleys of the Konkan were well clothed with timber; when vessels of fair size could navigate some of the bigger rivers and creeks that traverse the district; but in an unwise moment the right to cut down their forests was conceded to certain landholders. The right was ruthlessly exercised, and when Dr. Creighton visited Mahableshwar he was struck, as others had been sadly struck before him, by the bare red, laterite, hilltops between him and the sea. As soon as the woods which protected the soil had been destroyed, the soil was washed away. The creeks also became choked with silt and *débris*, and no vessels of any size can now sail up those creeks. But, as the plague is a ground poison, might it not be reasonable to suppose that the heavy rainfall had done its work in washing away any traces of imported poison from the neighbourhood of human dwellings? On the east side of the Ghâts the case was otherwise. There we had the heavy black cotton soil, and the rainfall was greatly reduced. As the south-west monsoon winds come up from the sea, laden with millions of tons of vapour, which are condensed by the colder temperature of the higher ridges, they pass on with only a short supply of moisture left in them for the Dekhan, and, even at a distance of only ten miles to the east of Mahableshwar, the rainfall amounts only to about 30 or 35 inches; but, small as it is, it does not, owing to the configuration of the country and the nature of the soil, drain away as fast as the heavy rainfall of the Konkan; and waterlogged soil, if it is not itself a congenial home for the plague germ, at all events lowers the public health and lessens the power of resisting onslaughts of the disease. The effect of a heavy rainfall in checking plague mortality had

been noticed in China, where the people believe that the plague is favoured by a long continuance of dry weather, and that a downpour for two or three days will stop it. We have it, on the testimony of Mr. Fraser, the Consul at Pakhoi, that, as a rule, the summer rains, by washing the streets, put an end to the plague for the year. And the cessation of plague at Naples, in the seventeenth century, seems to have been ascribed to a similar cause; for we learn from the author of that most fascinating book, "John Inglesant," that the night after Inglesant had met the friar in Naples, there was "the sound of abundance of rain" and "the plague was stayed." And then again the higher temperature of the Konkan districts may have conduced to the comparative immunity from plague enjoyed by the people of Ratnagiri. The climate of the Konkan is warmer and damper than that of the high-lying Dekhan. It is warmer than that of Bombay; and though the steady rise during a long series of years of the level of the sub-soil water in Bombay, caused by the filling up of the flats and the blocking of several outlets to the sea undoubtedly had a most prejudicial effect on the public health and possibly prepared the way for the plague by predisposing people to disease, yet, according to Mr. Baldwin Latham, who, many years before the outbreak of the plague, had reported on the sanitary condition of Bombay, great dryness of the air is one of the climatic factors which favour the growth of an epidemic of plague. He found that the conditions, when measured by the dryness of the air, were identical in the several London epidemics and in the Bombay epidemic of 1896-97. Similar conditions may have favoured the prevalence of plague in the Satara villages. The subject is one of the gravest concern to the whole civilised world; and he (Mr. Birdwood) could only hope that, as Dr. Creighton had studied on the spot the questions connected with recent extensions of plague in India, he would, on some future occasion, supplement the conclusions he had arrived at as regards one of the causes of its continued prevalence in the Dekhan and the Punjab, with a paper on the results of his enquiries regarding the repeated epidemics in Bombay during the past nine years.

Dr. W. Scott Tebb (Public Analyst for Southwark) said he had not had any practical experience of plague, but as bacteriologist of one of the Metropolitan boroughs was much interested in the subject under discussion. They had learnt from Dr. Creighton's valuable paper the conditions under which plague thrives. There is, he (Dr. Tebb) thought, no doubt that this disease might arise by contagion from person to person; this was clearly indicated by the Vienna cases in 1898, when the laboratory attendant Barisch who had to do with plague material contracted the disease and communicated it to Dr. Müller his doctor and also to one of the nurses. The most important cause, however, which contributed to the propagation of plague was, as Dr. Creighton had shown, the presence of filthy conditions in and around houses, and it was these foul conditions, whether of soil or air, which were not only responsible for plague but also for typhoid, typhus, cholera, and small-pox. The theory that certain diseases were due to a micro-organism had tended to obscure and to throw into the background the fact of their insanitary origin. For his own part, as the result of experience, he had come very much to doubt the *rôle* played by certain so called "pathogenic organisms," that was to say, whether they were the actual cause of the disease in question. Take the comma bacillus of Koch. That was, at one time, confidently stated to be the cause of cholera, but Pettenkoffer, Klein, and others had shewn that this bacillus might be eaten with impunity and without producing any deleterious results whatever. Then there was the so-called "typhoid bacillus" of Eberth. In 1880 this was heralded as a great discovery, but it had since been shewn by Remlinger and Schneider that this bacillus is practically ubiquitous. Thus it occurs in the alimentary canal of those unaffected with typhoid fever, it occurs in potable waters, in the soil, and contributes to the microbial flora with which we are normally surrounded; in fact the bacillus is so widely diffused, that if it were the actual cause of typhoid fever the human race would long since have been exterminated. With regard to the "plague bacillus" of Kitasato it was shewn by Aoyama that the bacillus in the blood of patients differed from that found in the buboes. Crookshank says, "it is quite possible that the so-called plague bacillus is really identical with the bacillus of hæmorrhagic septicæmia and the real nature of the contagium in bubonic plague is unknown." But whatever be the truth about these important questions, and there certainly seemed much difference of opinion in the medical profession, he (the speaker) had no doubt that the microbial theory of disease colours all our ideas. Everything centred round the micro-organism. As Dr. Creighton had said, we "think bacterially," and the effect of this attitude of mind was shewn very clearly in the Report of the Indian Plague Commission of 1901. The Commissioners found that dirt in houses is not a good medium for the cultivation of the "plague bacillus" and hence "we can hardly find justification for the belief that plague is a filth disease in the sense that the growth of its bacillus is favoured by the presence of dirt." Again, in so far as dirt was associated with moisture, it might retard the destruction of the bacillus, otherwise "dirt in a house" appeared to be "a matter of indifference." Finally, we have the extraordinary conclusion that "a clean room may constitute as dangerous a nidus of infection as a dirty room, insomuch as the specific micro-organisms of the disease may effect a lodgment or remain in the room in spite of any amount of sweeping and cleaning." That was a truly hopeless doctrine, and one he was sorry to say for which bacteriology was mainly responsible. In his opinion, the only way to eliminate plague was

to attend to the sanitary surroundings of the individual. Plague and small-pox thrived in old London in the terribly filthy conditions which then prevailed, and they likewise flourish in India and China to-day; and it was only by making the people clean, in their habitations and in their towns, that these diseases could ever be effectually eradicated.

Lieut.-Col. ALLAN CUNNINGHAM said that, having lived in India for twenty-three years, he had listened with very great interest to Dr. Creighton's paper. It was one the saddest papers with reference to the inhabitants of India he had ever heard. The most important conclusions arrived at seemed to be that, unless the inhabitants would give up building with kutcha masonry—(mud)—and revert to building with solid materials, there was not much hope of getting rid of plague. Yet, to get them to do so was nearly an impossibility, and for two reasons. First, the three hundred millions of people in India were intensely conservative; and if they could give up building with earth, they would not do so. Secondly, if they wished to give it up, he was afraid the mass of them could, not simply owing to their intense poverty. They had recourse of necessity to the surrounding earth, simply because it was the cheapest material to be found.

Dr. E. H. HANKIN said that the paper to which they had listened with so much pleasure showed that in India, at all events, the white man's burden was the coloured man's microbe. The statistics which had been brought forward by Professor Simpson made one wonder what would be the eventual outcome of the present outbreak should it cross the Indian frontier while retaining its present virulence. Reference had been made to the relation of fleas to plague. The important discovery made by Captain Liston on the subject was that in the absence of plague the fleas proper to rats were not to be found on human beings; but in the case of persons residing in a plague-infected house where rats had already died the peculiar rat fleas were found on those persons. That obviously was a means by which the microbe could be transmitted. The important question for consideration, was, how long the present outbreak was likely to continue in India. In spite, of what had been said, arguing from the analogy of previous Indian outbreaks, if those outbreaks had only lasted ten or twelve years, he failed to see why the present outbreak should last longer than that. The fact that during the current year plague was more virulent than in previous years was not an important argument, because the disease had generally been most virulent just prior to its disappearance. To say that because Indian plague resembled the Black Death which lasted for 300 years, the present Indian plague was likely to last as long, did not appear to be a convincing argument, inasmuch as one event occurred in Europe, and the other in India. As far as the evidence went, whether an outbreak in India had been a limited or an extended one, it had never lasted for such an excessively long period. India in the past had been singularly free from prolonged pestilence, and he failed to see why the same state of affairs should not persist.

Dr. CREIGHTON, in reply, said he could hardly, at that late hour, deal in detail with the many points raised by the various speakers. He believed he could make some reply to Colonel Thomson's instance of Hurdwar. With regard to Professor Simpson's remarks, he did not take so pessimistic a view as that gentleman on the extension of the area of plague in India, and he did not expect an extension into Europe. As to Colonel Cunningham's practical answer, he was well aware how valid it was. At the same time one must recognise the facts, and if there were to be any deliberate policy adopted to shorten the duration of plague and to anticipate the pressure of events, the kind of habitations of the peasantry must be looked to more than anything else. One knew how impracticable such suggestions often were, and no one felt that more than himself, coming fresh from seeing the kind of villages in the plague-infected districts. Numerous criticisms had been made by Mr. Birdwood and other speakers who had taken part in the discussion to which he would gladly have replied had time permitted, and he promised to entertain them at greater leisure.

At the conclusion of the meeting, a hearty vote of thanks was accorded to Dr. Creighton for his able and important paper.

IRISH EMIGRATION STATISTICS.

The emigration statistics of Ireland for 1904 show that although there was some falling off as compared with 1902-3—a decrease of 3,244—the actual emigration, notwithstanding the diminished population, was considerably larger than in 1897 and 1898. The emigrants who left the Irish ports during the year 1904 numbered 37,415, or 8·5 per 1,000 of the estimated population of Ireland in the middle of the year. The number of males who emigrated was 17,524, or 1,779 less than in the previous year, and the number of females 19,891, a decrease of 1,465. Of the total emigrants in 1904 there were 36,902 natives of Ireland, and 513 were persons belonging to other countries. In comparison with 1903 the number of emigrants, natives of Ireland, shows a decrease of 2,887, and the number of persons belonging to other countries a decrease of 357. The emigration returns were first collected in 1851 and from May of that year to the end of 1904, the total number of emigrants, natives of Ireland, who left Irish ports was 3,997,913—2,076,072 males and 1,921,841 females. The highest

number of emigrants in any one year was 190,322 in 1852, and the lowest 32,241 in 1898. In the decade from 1866 to 1875 the average number of emigrants was 74,667, in the decade 1856 to 1865 the average annual number amounted to 88,272, and in the four preceding years, from 1852 to 1855, the number averaged 148,985 annually. After 1887 there was a gradual annual decline to 35,895 in 1894; in 1895 the number rose to 48,703; it then fell to 38,995 in 1896, to 32,535 in 1897, and to 32,241 in 1898. It rose to 41,232 in 1899, and to 45,288 in 1900, and fell to 39,613 in 1901, rising to 40,190 in 1902. The number of emigrants fell to 39,989 in 1903, and to 36,902 in 1904.

It is not only that the emigration from Ireland has been continuous and large. It has taken away from the country the cream of its manhood and its womanhood. Of the 37,415 emigrants in 1904, 62·9 per cent. were between the ages of 15 and 25, and 20·9 per cent. between the ages of 25 and 35. The quinquennial age-period, 20-25 years, furnished the largest number of both male and female emigrants—the persons of this age forming 40·2 per cent. of the entire number of emigrants. The only quinquennial age-period in which the females greatly outnumbered the males is that between 15 and 20, when the number of females was 6,175 and of males 2,309. Of the males who emigrated, 17,524 in number, 1,527, or 8·7 per cent., were described as married men or widowers. Of the 19,891 females, 2,265, or 11·4 per cent.. were returned as married or widowed. Of the 15,036 persons between the ages of 20 and 25 years, 290 only were married—66 males and 224 females.

An immense majority of the emigrants, 30,580, or 82·9 per cent., went to to the United States, and 9·4 per cent. to Greater Britain. The emigration to British colonies was insignificant. Canada took most of it, the number being 2,083. Only 336 Irish emigrants went to Australia in 1904, 123 to New Zealand, 298 to South Africa, and 6 to India. It is worthy of note that of the 28,755 Irish emigrants who travelled as steerage passengers to the United States there were 10,739 whose passages were paid for in America.

INDUSTRIAL ALCOHOL IN AMERICA.

The following particulars respecting the action taken in the United States in respect to industrial alcohol are from the *Pharmaceutical Journal*:—

In the matter of alcohol used for manufacturing purposes Great Britain and America suffer at the present moment from the same disabilities. At one time it appeared as though America would be the first to remedy this defect in legislation. In the United States the greatest opposition has not come from the Inland Revenue authorities, but, curiously enough, from enthusiastic teetotalers.

The United States, however, are not likely to be behindhand in this respect much longer. The committee of manufacturers which has the matter in hand has just drafted a new Bill, having decided to abandon all other measures dealing with the same subject which have been presented in Congress. The great majority of legislators are now in sympathy with the claims of manufacturers, so that in all probability the measure just drafted will not meet with the fate of its predecessors. The chief features of the Bill are briefly as follow:—Distilled spirits of high alcoholic strength, when rendered unfit for use as a beverage, to be removed from distillery warehouses, free of tax, under certain regulations to be prescribed by the Commissioner of Internal Revenue. The tax on high-proof alcohol and high-proof Cologne spirits to be reduced to 70 cents. per proof gallon; the tax on all other forms of distilled spirits to be reduced to 80 cents. per proof gallon.

In order that the Revenue may not suffer as a result of these proposed concessions it is provided in the Bill that an additional tax be placed on rectified or compounded distilled spirits used solely as a beverage. By this means it is estimated that the yield from the duty on spirit, under present conditions, will amount to 157 million dollars, as compared with a revenue in 1904 of 129 million dollars. It will be judged from this that the Internal Revenue authorities are not likely to put much opposition in the way of the Bill. Stringent regulations are to be enforced with a view to diminishing the risk of industrial alcohol being used for illicit purposes. Spirit removed free of tax from distillery warehouses must not be stored on any premises in which the business of a distiller, rectifier, wholesale or retail liquor dealer is carried on. The penalty for rectifying such spirit so as to remove any substance which has been added for the purpose of rendering it undrinkable is to be not less than 500 dollars and not more than 5,000 dollars, and imprisonment for not less than six months and not more than three years.

OBITUARY.

George Handasyde Dick. — Mr. G. H. Dick died on the 17th ult. at his residence at Strone, N.B., after a long illness. He was born at Bridgeton about 1838 and went to India early in life for a commercial training. On returning to England he set up for himself as an East India merchant at Glasgow. Other firms were formed later in connection with his business in Manchester, Bombay, and Rangoon, of which firms he was chief partner. He was President of the Chamber of Commerce, and at one time Rear-Commodore of the Clyde Yachting Club. He was elected a member of the Society of Arts in 1900.

GENERAL NOTES.

THE CURRANT TRADE AND A CURRANT BANK.—The coming currant crop of the Morea promises to be so large that the Greek Government will no longer encash the duty in kind. It is expected that the amount of currants available for export will be increased by 15 per cent., and as consumption seems to be on the decline in most markets the future for the currant growing is not bright. The Currant Bank was founded when the Retention Law was passed, and derives its capital from the proceeds of the currants which are deposited in its stores by exporters without the bank giving any equivalent for them. During the first year of its existence, writes Mr. Consul Wood in his Report dated April 12th last (3369, Annual Series), the bank encashed several millions of drachmæ from the annual sales of these retention currants, and these moneys were, according to the spirit of the bank's charter, distributed in loans, bearing small interest, to currant growers, either in the shape of cash, sulphur, or sulphate of copper, which the bank imported, as being necessary for the protection of the vineyards against the oïdium, peronospors, and other maladies. So long as currant growers were fairly prosperous a portion of the loans was annually repaid but of late years their condition has become so precarious that they have been quite unable to carry out their obligations, and the bank has been almost completely drained of its moneys. Being thus without capital, it cannot afford to import sulphate of copper, which is the only remedy against the peronospors malady, and as growers generally cannot afford to do so, a reduction in the area under cultivation would seem inevitable. There has ceased to be any demand in France, Italy, and Germany for wine made from currants. On the other hand, the growth of sultanas, the favourite raisin, is largely on the increase.

TEA AND DUTIES.—A reduction in the tea duty was not unexpected. At the end of March there were 127,000,000 lbs. in bond compared with 101,000,000 lbs. on the corresponding date of last year. To what extent the consumer will benefit from the remission of duty is doubtful. The poorer kinds of tea were never cheaper in Mincing-lane, or as cheap as during the past year, when the duty was 8d. Duty is only one of the determining factors of price, and with an 8d. duty the newspapers have been advertising a well known tea dealers' "really good tea" at 1s. 2d. per lb. The variations of the duty have been many. From 1801 to 1805 tea selling at or above 2s. 6d. per lb. was subject to a duty ranging from £30 to £95 2s. 6d. per cent.; if sold under that price from £20 to £65 2s. 6d. From 1806 to 1818 a uniform duty of £96 per cent. was imposed, which continued with an additional duty of £4 per cent. on tea selling at above 2s. per lb. down to 1833, the last year of the *ad valorem* duty. In 1834 and 1835 the duty ranged from 1s. 6d. to 3s. per lb. according to the class of tea; from 1836 to 1839 all kinds of tea were rated at 2s. 1d. per lb. with 5 per cent. in addition from 1849 to 1852. In 1853 the duty was 1s. 10d., and from that year the duty was gradually reduced, till in 1865 it was fixed at 6d. On 1st May, 1890, the duty was reduced to 4d., and was raised again to 6d. on the 6th March, 1900, and to 8d. last year. From July 1 next there will be a return to the sixpenny duty. Almost all our tea now comes from British India and Ceylon, Natal supplying a little, but the imports from China show signs of renewed expansion, and Java and other foreign centres are likely to be serious competitors before many years have passed.

TRADE OPENINGS IN MANCHURIA.—It may be gathered from Mr. Consul Little's report on the trade of Newchang (No. 3354, Annual Series), that after the war Manchuria is likely to be a good market for labour-saving implements. Contrary to what is the case in most parts of China, farming is carried on in Manchuria on a comparatively large scale, the average size of the holdings being 100 to 200 acres, extending occasionally to 1,000 acres. There is therefore ample scope for the use of labour-saving implements, for which a demand may be expected to arise after the war. Mr. Little says that just before the war a wealthy native, who had acquired a large property in the Imperial Hunting Park, which has now been thrown open to settlers, placed an order with a foreign firm for a complete set of steam ploughing and threshing tackle, costing in all over £1,000. The demand is likely to be stimulated by the scarcity of draught animals from which farmers will be sure to suffer owing to the large numbers used up in the war.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JUNE 19...British Architects, 9, Conduit-street, W., 8 p.m.

TUESDAY, JUNE 20...Asiatic, 22, Albemarle-street, W., 3 p.m.

Horticultural, Vincent-square, Westminster, S.W., 3 p.m. Rev. Prof. Henslow, "Plants of the Bible."

WEDNESDAY, JUNE 21...Meteorological, 70, Victoria-street, S.W., 4½ p.m. 1. Mr. George C. Simpson, "Normal Electrical Phenomena of the Atmosphere." 2. Mr. S. P. Fergusson, "Two new Meterological Instruments: 1. Automatic Pole Star Light Recorder, and 2. The Ombroscope."

Geological, Burlington-house, W., 8 p.m.

Microscopical, 20, Hanover-square, W., 8 p.m. 1. Mr. A. E. Conrady, "Theories of Microscopical Vision." 2. Mr. Edward M. Nelson, "The Tubercle Bacillus."

British Archæological Association, 32, Sackville-street, W., 8 p.m.

THURSDAY, JUNE 22...Antiquaries, Burlington-house, W., 8½ p.m.

FRIDAY, JUNE 23...Art Workers' Guild, Clifford's-inn Hall, Fleet-street, E.C., 8 p.m. Mr. J. Starkie Gardner, "The Monumental Uses of Bronze."

SATURDAY, JUNE 24...Botanic, Inner Circle, Regent's-park, N.W., 3½ p.m.

Journal of the Society of Arts.

No. 2,744. VOL. LIII.

FRIDAY, JUNE 23, 1905.

FINANCIAL STATEMENT.

The following statement is published in this week's *Journal* in accordance with Sec. 40 of the Society's By-laws:—

TREASURERS' STATEMENT OF RECEIPTS AND PAYMENTS FOR THE YEAR ENDING MAY 31ST, 1905.

ANNUAL GENERAL MEETING.

The Council hereby give notice that the One Hundred and Fifty-first Annual Meeting for the purpose of receiving the Council's Report and Treasurers' Statement of receipts, payments, and expenditure during the past year, and also for the election of officers and new members, will be held in accordance with the By-laws on Wednesday, 28th June, at 4 p.m.

(By Order of the Council),
HENRY TRUEMAN WOOD,
Secretary.

VIVA VOCE EXAMINATIONS IN MODERN LANGUAGES.

The following is a list of the *Vivâ Voce* Examinations which have been held since the last announcement in the *Journal* for February 3, 1905:—

Place of Examination.	Date.	Number of Candidates.	Passed with Distinction.	Passed.	Failed.
French:—					
Crouch-end Council School	March 29, 1905	40	5	28	7
Willesden Polytechnic..	March 30, 1905	22	3	11	8
Acton and Chiswick Polytechnic	March 31, 1905	31	2	21	8
Manchester Education Committee	May 16, 1905.	21	4	11	6
Birkbeck College (Candidates from London Polytechnics)	May 30 & 31, 1905.	69	6	51	12
Battersea Polytechnic (Candidates from London Polytechnics)	June 1, 1905.	33	4	18	11
L.C.C. Evening School, Sussex-road, Brixton..	June 14, 1905.	30	2	23	5
L.C.C. Evening School, Queen's-road, Dalston	June 15, 1905.	23	2	16	5
L.C.C. Evening School, Choumert-road, Peckham	June 16, 1905.	26	1	20	5
L.C.C. Evening School, Tottenham rd., Kingsland	June 17, 1905.	23	6	13	4
German:—					
Manchester Education Committee	May 19, 1905.	9	4	5	—
City of London College (Candidates from London Polytechnics)	May 31, 1905.	36	6	19	11
Spanish:—					
Manchester Education Committee	May 17, 1905.	18	3	8	7
Portuguese:—					
Manchester Education Committee	May 15, 1905.	5	—	4	1
		386	48	248	90

The Examiners were Mr. E. L. Naftel for French, Professor H. G. Atkins, M.A., for German, Professor Ramirez for Spanish, and Mr. J. d'Oliveira e Silva for Portuguese.

CONVERSAZIONE.

The Society's Conversazione will be held, by arrangement with the Council of the Royal Botanic Society, in the Gardens of that Society, Inner-circle, Regent's-park, on Tuesday evening, the 4th of July, from 9 to 12 p.m.

The central portion of the Gardens only will be used. The Gardens will be illuminated with coloured lamps, and also by the Kitson Incandescent Oil Light. The Conservatory and the Club-house will be open.

The Reception, by Sir William Abney, K.C.B., F.R.S., Chairman, and the other Members of the Council, will be held at the entrance to the Conservatory, near the Broad Walk, from 9 to 10 o'clock.

An Exhibition of Growing and Cut Roses and other Flowers will be arranged in a marquee in the grounds by Messrs. W. Paul and Sons, of Waltham Cross.

A collection of Liliums in Pots will also be arranged in the Corridor.

A Selection of Music will be peformed by the String Band of the Royal Artillery in the Conservatory, and by the Band of H.M. Grenadier Guards in the Gardens, commencing at 9 o'clock.

Two performances of Selections from Pastoral Plays will be given in the Gardens by Mr. Patrick Kirwan's Idyllic Players at 9.30 and 10.45 p.m.

A concert and entertainment, including a scene from "The School for Scandal," will be given in the Club-house, from 10 to 10.45 p.m.

Light refreshments (tea, coffee, ices, claret-cup, &c.) will be provided.

Each member is entitled to a card for himself (which will not be transferable) and a card for a lady. These cards have now been issued. A limited number of tickets will also be sold to members of the Society, or to persons introduced by a member, at the price of 5s. each, if purchased before the day of the Conversazione. On that date the price will be raised to 7s. 6d.

Members can purchase these additional tickets by personal application, or by letter addressed to the Secretary at the offices of the Society, John-street, Adelphi, W.C. In all cases of application by letter a remittance must be enclosed. Each ticket will admit one person, either lady or gentleman, and must be signed by the member applying for it.

Tickets will only be supplied to non-members of the Society on presentation of a letter of introduction from a member.

THE WATER OF THE SOIL.

The following is an abstract of a report by Dr. J. Walter Leather, the Agricultural Chemist to the Government of India, communicated by Mr. Sidney Preston, C.I.E., Inspector-General of Irrigation, Calcutta:—

A correct knowledge of the quantity of water in the soil under varying conditions, the portions of the rainfall that respectively pass permanently into the soil or evaporate, the nature and velocity of its movement, and the quantity of water required by crops, is of agricultural importance in all countries, but specially in the tropics if the rainfall is unevenly distributed, and long dry periods occur annually. Yet little is known in the quantitative sense of the soil water of India. Probably the reason is twofold. The period of dry weather may be bridged over, and crops brought to perfection by running moderate quantities of water on the land, and the writers of text-books on soils, especially the earlier ones, have spoken of the rain-water descending into the soil without commenting on the nature of the phenomenon, and they then liken the rise of water during dry weather to that which takes place if a lump of sugar is dipped into a cup of tea, or a lamp wick into the oil well. Probably nothing has militated more against an exact study of the subject of soil moisture than these illustrations. They seemed to fit the case exactly, for if a lump of dry earth is similarly placed in water the latter rises rapidly like the tea into the sugar. But if the conditions under which water exists in the soil may be thus explained it is obvious that no drought, however prolonged, would affect the growing crops provided there is underground water, and conversely, since the tea rises an inch into the sugar in a few seconds and would pass downwards even more rapidly, the heaviest of rainfalls must be readily absorbed by the soil. But plants suffer from drought when very large quantities of water are only a few feet from them, and if a heavy shower occurs, the soil is frequently unable to absorb it all, some flowing away into the nearest drainage channel. It is only when one considers the subject in this broad, quantitative sense that the imperfection of such text-book illustrations becomes apparent.

If soil is examined under the microscope it will be ound that the greater part of it is derived from rocks. The size of most of the pieces is quite small, many of them measuring not more than ·001 mm. in diameter. We may further take the soil, separate the coarser fragments with sieves, and then further separate that which passes through the sieves into different grades of fine material by means of running water. If we can effect a separation of those particles which measure, for example, on the average ·002–·008 mm. from those which measure ·008–·016 mm. we shall obtain an interesting insight into the relative quantities of such material. The figures show that of every 100 lbs. of each of the soils a very high proportion consists of very fine material, and that even in a stony soil like that in the Dun the amount of fine material is greater than one might have expected.

Unfortunately, we have no means of determining the amount of true colloid clay in a soil. Most of it will separate with the finest silicious matter, but some of it adheres sometimes to the coarse material. This is especially the case with the Regur. On the other hand, it is not possible to prevent a good deal of fine silicious matter from separating with the greater part of the clay. Consequently, the finest material which can be separated consists of clay and sand. In the case of Black-cotton soil, this is probably largely true clay, but the microscopical examination of the corresponding part of the Cawnpore soil shows it to consist principally of non-colloid silicious matter. From these mechanical analyses of soils information regarding the number of particles per unit volume and the total surface possessed by them is obtainable. If we assume them to be spherical, and that the specific gravity lies between 2·5 and 2·7, we may calculate both the above quantities. It is true that they are not spherical, but of somewhat irregular shape, but since a knowledge of both the quantities in question is of importance to our subject approximate information is valuable. We may notice the following facts which these calculations demonstrate:—

(*a*) By far the greater number of soil particles are very minute.

(*b*) By far the greater number of them are much about the same size, and

(*c*) The total surface area of each cubic foot is very great.

The next point to notice is that under no circumstances can any space be entirely filled by this soil material. Since the particles are not bodies of regular shape, with plain surfaces, there must be a certain amount of the space unoccupied by this mineral material, and we call this the *interspace*. How great is this interspace? An answer may be obtained by two means. The first is a geometrical one. If we assume a series of spheres of diameter 1 to be packed together, they may occupy the spaces in either the arrangement A or B of the diagram. (Figs. 1, 2.) The former is the looser arrangement, and admits of interspaces equal to 47 per cent. of the whole space; the latter, B, is the closer formation, and the volume of the interspace equals 26 per cent. of the whole. If, now, smaller spheres be packed up into the interspaces of either of these formations so as to touch the larger spheres, an *equal number* of such smaller spheres will be required, and the volume of interspace will become materially diminished. If this process can be indefinitely repeated, the volume of interspace will become indefinitely small. If, then, the soil consists of approximately equal numbers of particles of certain sizes, it would be possible for the volume of interspace to fall to a small percentage of the whole. But by far the greater number of the particles in soils are much about the same size mixed with comparatively few larger ones, and consequently under no conditions can the volume of interspace fal

to a very low figure. It must, indeed, be usually a large proportion of the whole. It will be least in the case of a soil containing the most uniform number of particles of the several sizes, and this is probably the case in *sandy* soils. This is more or less substantiated by the fact that sandy soils weigh considerably more, usually one-quarter more than loams and clays, whilst the specific gravity of the material shows a difference of only about 1 to 25.

FIG. 1.

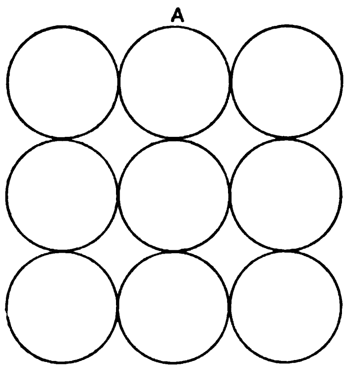

FIG. 2.

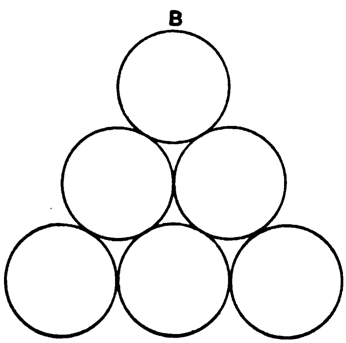
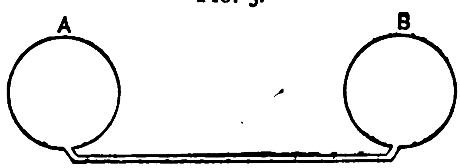


There is another way of determining experimentally the value of such interspace. If a block of soil of specified dimensions be taken, dried thoroughly, and then weighed, and if the mean specific gravity of the material be determined, the weight of a volume of water equal to dry soil may be readily calculated, and this, compared with the weight of a volume of water equal to the dimensions of the soil *in situ*, will provide the relative volume of interspace. Before passing to a consideration of the movements of water in soil it is desirable to point to two important facts. The first is that the soil of our cultivated fields two to three feet below the surface is never dry, and usually contains considerable quantities of water. The explanation of this will appear presently. The second is that the surfaces of the soil particles are "clean" in the same sense that a plate of glass is that has been treated with caustic soda solution. If water be brought on to such a piece of glass it will flow uniformly over it, like mercury does over a surface of amalgamated zinc, and the water will not tend to collect itself up into drops. This state is due to the fact that the soil is generally in a basic condition. Consequently water has no difficulty in flowing over such surfaces, even in very thin films. Suppose rain falls? The first water will flow in between the uppermost layer of particles. But having thus occupied these spaces, its further progress is impeded, for it has enclosed the gases which are present in the interspaces of the stratum immediately below. These gases cannot escape upwards because they would require greater force then they possess to break the enclosing films of water. Nor can they escape downwards because they are bounded by the underground water. More rain-falling pressure is brought to bear on the first quantity, and it can only pass down by one means—it must pass between the gases and the mineral matter. They are thus surfaces of water separated from one another by small quantities of gas. The form which such water surfaces will assume at the narrowest poiuts will compel it to run together, thus forming an intercepting film. Thus, with a lengthened rainfall the interspaces of the soil will become uniformly occupied by water and gases. If the rate of supply of water is greater than can pass through such minute spaces in unit of time, then it remains on the surface or runs off into the nearest channel. It is also to be noticed that the enclosed gases will be under an increased pressure at this time. If the water supply is limited to the rainfall, this will be nominal. If water is standing on the surfaces, this pressure becomes considerable. Moreover, equilibrium will not be established instantaneously through thick strata of soil. If pressure is applied to any vessel containing a liquid and a gas, it is transmitted to all parts of the vessel at once. But if two vessels, such as A and B (Fig. 3), containing liquid and gas are connected at the lower surfaces by a comparatively very narrow tube, and pressure is applied to A, equilibrium will not be established in B until a certain quantity of the liquid has flowed from A to B, and this would occupy time.

FIG. 3.

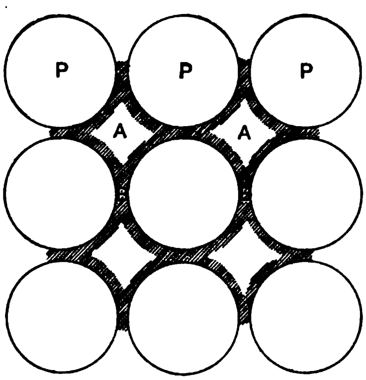


This is the case in the soil, and the pressure which an addition of water produces near the surface almost instantaneously, requires an appreciable time to be produced in the lower strata. This is doubtless one reason why drainage recommences even in constantly wet weather only after the lapse of some hours from the time when the rainfall recommences, and for the same reason it does not cease suddenly in the subsoil with cessation of rain.

If the atmosphere happens to remain saturated with moisture no water will evaporate. But usually the humidity decreases rapidly after rain ceases, and although the degree of humidity at this time varies greatly, it will be sufficient for our purpose to consider an atmosphere with 75 per cent. relative humidity at a temperature of 80° Fahr. Such an atmosphere is capable of taking up 2·83 grains of water per cubic foot. Furthermore, it is never still, but moves in various directions over the surface of the land, not only horizontally, but at other various angles to the horizontal. We need only consider a low velocity, namely, ½-mile per hour. Such a velocity would bring 2,640 feet of air over each square foot of surface per hour, or 63·360 feet per day. If a stratum of such air only one foot thick is considered then the air which comes in contact with each square foot of surface per day is capable of taking up 179,300 grains, or 395·3 lbs. of water. These conditions show that the atmosphere is capable, even under the very limited conditions stated, of readily absorbing any moisture which is actually exposed to it at the surface.

Turn to the water in the surface soil and consider its position. (Fig. 4.)

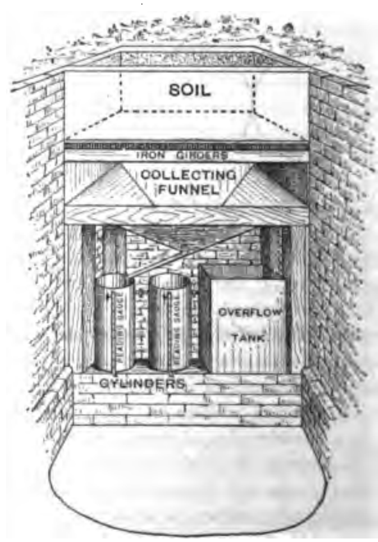
FIG. 4.



P P P represents soil particles, A A water films between the uppermost particles, B B similar films between those particles next below. At the points, A A, in the diagram, its surface is exposed to the atmosphere, and evaporation will take place. One of two things must now happen. If water can pass from the points B B to A A sufficiently rapidly, then evaporation will continue there. If, on the other hand, the water is unable to pass rapidly enough from B to A, then these will disappear, the surface particles will become dry, and evaporation can take place only at the points B B. In the former case it will be clear that water passing from B B to A A will reduce the thickness of films B B, unless water flows from similar supplies underneath so fast as to supply the loss. If the second of the supposed conditions ensues, and the evaporation has to take place not at the points A A but at points such as B B, below the surface the rate of evaporation must be infinitely slower, for the water at B B cannot pass from the liquid to the gaseous state until the previously evaporated water diffuses through the narrow passages, A A.

We will now turn to a consideration of the proportion of the rainfall that annually evaporates again into the atmosphere and that which percolates, after which it will be seen that we have some data on the subject of the rate at which water descends. There is one very simple and accurate method of determining what portion of the rainfall percolates through soils. If a rectangular mass of soil, whose upper surface is exposed to the weather, is isolated, and whatever water percolates from it is measured, this quantity is readily calculated into inches per acre. The difference between this quantity and the rainfall will either be in the soil, or it has evaporated, or some of it, in the event of heavy rainfall, may have run off the surface without being absorbed at all. The latter contingency will be excluded from our consideration, because, though it occurs so generally in India, it plays no part in the data that will be produced. Such masses of earth have been called "Drain gauges," by Lawes and Gilbert; in America, they are called "lysimeters." There are two modes by which such masses of earth may be isolated. The one is to pack earth into a suitable receptacle provided with a false bottom, and supplied with vessels to collect and measure the water which percolates; the second method is the one adopted by Lawes and Gilbert. The attached diagram will explain the general arrangement of these gauges. (Fig. 5.)

FIG. 5.



They consist of blocks of earth which have never been disturbed. The earth which originally surrounded these blocks was removed, and the containing walls built. Iron bars were placed horizontally underneath, and then the collecting vessels attached.

Such earth is obviously a much safer guide to the information in question than when recently disturbed earth is used. But these gauges require great care in construction, and even then a crack may form. However, this source of error is readily detected, because much larger quantities of water would percolate than should be the case, and the water would contain little or no nitrate, whereas true percolation water contains very material quantities of these salts. Three such percolation gauges were constructed at Rothamsted in 1870, and they consist of blocks measuring 7 feet 3·12 inches $\times$ 6 feet $=$ 1-1000th acre in surface area. They are respectively 20", 40", and 60" thick. They are kept entirely free from vegetation.

Information regarding the moisture condition of Indian soils is urgently needed, and it is hoped to see several gauges constructed here from which to obtain records similar to those of Rothamsted. A beginning has been made at Cawnpore, where Mr. Hayman, the Deputy Director of Agriculture of the United Provinces has constructed four gauges, two of three feet and two of six feet thick. As they were only made in 1903 it is too early to publish figures, but one thing may be mentioned. At the conclusion of the 1903 monsoon the gauges ceased running, and no measurable quantities of percolation water were obtained after the middle of November. A block of soil three feet thick cannot produce percolation water until a certain amount of water is in it. From such soil as that at Cawnpore this would not be less than 15·5 lbs. per cubic foot, which is equivalent to 46·5 lbs., or nine inches of rainfall in the first three feet. Now in June the following rainfalls were received: 13th ·33 inch, 16th ·07 inch, 22nd 3·63 inches, and 27th 0·7 inch. By the end of the month water was percolating from all the gauges. It is certain, therefore, that there must have been at the end of the hot weather a quantity of water equal to about 6 inches or 7 inches of rainfall in the first three feet of the soil.

The quantity of water required by crops is naturally a very important question, and the information we possess is far less accurate than we might wish. A good wheat crop may be assumed to weigh (grain and straw) some 5,000 lbs. per acre in the dry state, and assuming that 250 lbs. of water are transpired by each lb. of crop during growth the total amounts to 1,250,000 lbs. per acre, or 5·5 inches of water. A crop of sugar cane may be assured to transpire probably four times as much. The actual velocity of the minute currents which occur in the soil during wet weather has not been determined. It probably varies very greatly. Data among the Rothamsted records enable one to estimate approximately to what depth the year's rainfall descends in twelve months. Selecting 1893, the year in which the soil of the Broadbylk field was examined, the rainfall was 24·08. The drain gauges showed that of this rainfall 11·84 evaporated and 12·24 penetrated, this having occurred in the absence of a crop. The wheat crop may be assumed to have transpired about 962,000 lbs., equal to 4·28 inches, so that in the Broadbulk field there would only be 7·96 left to percolate. Even after a prolonged drought there is a still a large amount of water in the upper two or three feet of soil. It has been mentioned that in the soil of the gauges at Cawnpore there must have been some 30·35 lbs. of water in the first 3 feet at the conclusion of the hot weather. On the other hand, a heavy crop of corn does not require more than about 20 lbs. per square foot of the field, and yet not even a small crop could have been raised in the hot weather at Cawnpore without additional supplies of water. It seems highly probable that the velocity at which water can move in soils by capillarity is a far smaller one than has been generally supposed. This would explain the fact that plant roots situated at, say, 6 inches below the surface cannot obtain water from a point, say, 9 inches or 10 inches, quickly enough to satisfy their requirements. It would also explain why a single irrigation of, say, 2 inches of water has such a marked effect on a half grown crop after a period of dry weather. Such a quantity of water would rapidly spread itself through fully 8·10 inches of soil by gravity, and the plant would be able to make far greater use of the water than at an earlier period.

INSECT PESTS ON TEA ESTATES.

Mr. E. E. Green, Entomologist to the Ceylon Government, delivered an address before the members of the Maskeliya Planters Association on April 26th last, on insect pests. He described the tortrix caterpillar, whose natural enemies, the Ichneumon flies, were increasing. In one species of these, the grub attaches itself externally to the back of the caterpillar, and behaves like some of the more virulent of the parasites. "At first looking like a tiny greenish head, the grub rapidly increases in size at the expense of its host, which finally collapses and dies, but only when the parasite has no further use for it, and is ready to undergo its own transformation," passing first into the cocoon stage, finally emerging as a tiny four-winged fly with a slender elongated body. The white ant has also occasioned frequent complaint in the Maskeliya district by hollowing out the roots and stems of the tea bushes. It confines its work to the heart of the wood, leaving the active outside tissues untouched, so that the plant remains in an apparently healthy condition until the sudden final collapse, which is often precipitated by a shock or blow. The lecturer stated that this white ant had so far defied all his efforts to unravel its life history; although he had spent hours in making excavations around an infected area he had never succeeded in finding any nests.

Among the least conspicuous, but not least important pests, are the mites, of which four recognised species exist in Ceylon. These are the Indian Red Spider (*Tetranychus bioculatus*), the "ribbed mite" (*Ehylopus carinatus*), the "yellow mite" (*Tarsony-*

mus translucens), and the "scarlet mite" (*Brevipalpus obovatus*). The first mentioned is the least abundant on the tea. It lives exclusively on the upper surface of mature leaves, where it causes distinct rust-coloured patches. The "ribbed mite" is very common and widely distributed, and is responsible for the dull coppery line so noticeable upon tea bushes in the dry season. The "yellow mite" affects the youngest leaves and buds only, and is consequently most destructive to the flush. The signs of its presence are a hard leathery character of the young shoots, and a brownish discolouration of the undersides of the leaves. The "scarlet mite" is, in the lecturer's opinion, the most dangerous of the lot. It attacks under the surface near the base of the leaf, and eventually kills the tissues at this point, causing an extensive and premature fall of leaf. Bushes badly infested by this mite may be denuded of all mature leaves, and show only three or four young leaves at the tip of each twig.

The cause of the injury is too often unrecognised, or attributed to some obscure root trouble. Planters, fortunately, have in powdered sulphur a real specific against all these tea mites, and one that is easily procured and applied. Its effect appears magical. The most economical method of application is by the use of specially designed distributors, casting a fine cloud of sulphur, which settles evenly over the foliage and permeates even the thickest bush. This work can be done on a fine still day in dry weather. A stiff breeze will blow the cloud of sulphur away before it has had time to settle, and a heavy shower will wash it off too rapidly. If there is a heavy dew on the trees this moisture will retain the sulphur firmly on the leaves. Otherwise, it is found advisable to spray the bushes with plain water immediately before the application of the sulphur. The extra cost and trouble are more than repaid by the increased efficiency of the treatment.

About 10 lbs. of sulphur suffices to secure their extermination for each acre. In conclusion, Mr. Green urged the importance of not only always having spraying machines at the different estates, but also stores of various insecticides. The machines when not in use should be kept in working order, and have clean water pumped through them once a fortnight. Coolies should be encouraged to report (and secure specimens of) any insects found upon the tea. The planter should regard every insect as an enemy until certain of its harmlessness.

ENGLISH "ASSISTANTS" IN FRENCH AND GERMAN SCHOOLS.

Last year the French Minister of Public Instruction initiated, in conjunction with the Board of Education, a scheme whereby a number of young teachers (men and women) were appointed temporary "Assistants" for one year in French Lycées and Colleges. The scheme will continue in operation this year, and the French Ministry will shortly proceed to make fresh appointments. It is hoped that similar arrangements may be made with Prussia, with the exception that in this case there will be no posts open to women.

The main duty of the "assistant" will be to conduct small conversation classes for about two hours daily. Though not taking any part in the regular instruction of pupils he will, both in France and Germany, be considered in all other respects as the colleague of the masters. He will not receive a salary, but he will be lodged and boarded at the institution to which he is attached, subject to the provision that in Germany in certain cases a sum of about £65 (Marks 1,300) may be paid to him in lieu of board and lodging.

Candidates for such posts should preferably be graduates of some British University, and should forward their application, containing particulars of their course of study and qualifications, to the Director of Special Inquiries and Reports, Board of Education Library, St. Stephen's-house, Cannon-row, Westminster, S.W., enclosing testimonials in duplicate as to character, capacity, and teaching experience, and a medical certificate of health. It will also be necessary for each candidate to have a personal interview with the Director at his office.

All applications must be received on or before Saturday, the 8th July.

NOTES ON BOOKS.

MODERN CARRIAGES. By Sir Walter Gilbey, Bart. London: Vinton and Co. 8vo.

In this book the author gives an account of the various forms of carriages invented or in use during the Victorian era. In a former work, "Early Carriages and Roads," he dealt with the development of passenger vehicles from the date of their introduction into England until the coaching era.

Sir Walter Gilbey points out that the great improvements which were made in the roads during the earlier years of the nineteenth century naturally produced great changes in the building of carriages. Lighter and more elegant vehicles were demanded, and the clumsy old carriages were superseded. Messrs. Elliott and Holbrook were pioneers of the movement which eventually dispensed with the heavy perch under-carriages, and Mr. Obadiah Elliott's invention of the elliptical spring in 1804 was the foundation upon which many improvements have been built.

The author quotes Mr. Phillipson for the statement that Samuel Hobson, who began his labours about 1820, "may truly be said to have improved and remodelled every sort of carriage which came

under his notice, especially as regards the artistic construction." Travelling carriages, which once occupied the attention of one of the distinct branches of the coach-building trade, have ceased to be required since the introduction of railways. The chariot is another vehicle which has disappeared. It was a handsome carriage, and when used without a driving seat for travelling. it was called a post-chaise. The Brougham, which was first introduced in 1838, had a great effect in driving out the larger and heavier carriages. It owes its introduction to Lord Chancellor Brougham, and the first carriage of this design was built under the personal directions of the inventor, and was finished on May 15th, 1838. The original is now preserved in the Victoria and Albert Museum, South Kensington. The author writes respecting this: "Lord Brougham sold it in 1840 to Sir William Foulis; subsequently it was bought by Lord Henry Bentinck, from whom it was bought by Earl Bathurst. It has been used by many famous statesmen, Lord Beaconsfield and Mr. Gladstone among the number."

Sir Walter Gilbey gives a full account of many other private carriages, which shows how great a variety of designs are still used. Some are adaptations of older vehicles, and others entirely new ones. Of public vehicles he gives the history of the Omnibus. The great genius, Blaise Pascal, is said to have "conceived the idea of running public coaches, each to carry six persons, along certain specified routes" in Paris. With the assistance of influential persons he obtained a royal patent and put seven coaches on the streets. The fare was 2½d., and the Omnibuses were so well patronised that two new lines of route were adopted, and more coaches put on, the fare being raised to 3d. In spite of a certain amount of success the enterprise was given up after two years' experience. Sir Walter gives the date when the idea took practical shape as March, 1662, but it must have been earlier than this, as Pascal died on August 19th, 1662, and previously to his death he had managed the business for a time. The first London omnibus was put on the streets by Mr. Shilibeer in July, 1829. It was drawn by three horses, and carried twenty-two passengers from the "Yorkshire Stingo," near the bottom of Lisson Grove, Marylebone, to the Bank, the fare being 1s. Shilibeer was an undertaker and Thackeray referred in one of his books to the vehicles as "hearses for the living." There had, however, been an earlier venture of the same kind, for *The Public Advertiser* of January 18, 1772, mentions a "new contrived coach" to carry fourteen passengers at 6d. each from Charing Cross to the Royal Exchange.

The author enters fully into the history of the Hansom cab, which has been greatly modified since its original invention by Mr. J. A. Hansom, an architect, who died on June 29th, 1882. The new cab was patented in 1834, and a company was formed for the purpose of introducing it and effecting the needful improvements. In 1836 a fresh patent was taken out in the name of Messrs. Gillett and Chapman.*

Sir Walter Gilbey writes:—"The modern hansom is the combination of improvements devised by many ingenious builders. Mr. Evans of Liverpool, nd Mr. Marston of Birmingham, contributed to the amenities of the vehicle, but the name of Forder is that with which the hansom now in use is most intimately associated." In 1873 the Society of Arts awarded a prize of £30 to Messrs. Forder and Co., of Wolverhampton, for an improved two-wheeled cab.

This interesting account of modern carriages is fully illustrated, and contains much valuable information respecting the history of carriages still in use, and of those once popular but now passed away.

General Description of Sir John Soane's Museum, with brief notices of some of the more interesting works of art. Eighth edition. Oxford. Sm. 4to.

This is an enlarged edition (by Mr. Walter L. Spiers, the present curator) of the official guide to the Museum, and besides a description of the objects exhibited in the house at Lincoln's-inn-fields, it contains a series of ten illustrations of some of the chief treasures of the institution, such as Hogarth's pictures of the Election and the Rake's Progress, pictures by Turner, Canaletto, and Watteau, as well as the splendid alabaster sarcophagus of Seti I., King of Egypt about 1370 B.C., which was discovered by Belzoni in 1817.

The Practical Electrician's Pocket-book for 1905. Edited by H. T. Crewe. London: S. Renteli and Co., Ltd.

This little book is now in its eighth year, and besides a large amount of practical information for Electrical engineers brought up to date, it contains anditional sections on Steam Turbines and Alternators, and the section devoted to Polyphase machinery has been extended.

OBITUARY.

James Mansergh, F.R.S.—Mr. Mansergh, who died at his residence in Fitzjohn's-avenue, on the 15th inst., was a member of the Society of Arts since 1873, and specially interested in the work of the Society in connection with sanitary matters and water supply. At the Sewage Conferences of 1876 and 1878 his external drain trap was exhibited by Messrs. Doulton, and before the Conference on Water Supply held at the International Health Ex-

* These particulars are stated in an article in the *Journal*, from information received from Mr. Hansom (March 28th, 1873, vol. 21, p. 360).

hibition, he read a paper on "Sources of Water Supply," in July, 1884 (*Journal*, vol. xxxii., p. 870).

Mr. Mansergh was born at Lancaster, in April, 1834, and was educated at two private schools before he joined Queenwood College. Here he was for a time co-editor with Mr. Henry Fawcett (afterwards Postmaster-General) of the *Queenwood Chronicle.* In 1849 he became a pupil with Messrs. McKie and Lawson, Civil Engineers, of Lancaster. About 1855 he set sail for Brazil, in the capacity of contractor's engineer and district agent, being one of four employed on the first section of the Don Pedro II. Railway, which connected Rio de Janeiro with the interior. His three companions were invalided and he alone remained to finish the plans. He returned to England and joined in partnership with his late chief, Mr. McKie. This partnership continued for three years, after which he came to London and undertook a large main sewerage contract at West Ham. The undertaking with which Mr. Mansergh's name is more especially connected is that of the Elan Valley Water Scheme for Birmingham which was opened by the King in 1904, and it is said that when as a young man he was travelling in the district he first conceived the idea of this great undertaking.

Mr. Mansergh was elected a Fellow of the Royal Society in 1901. He became an Associate of the Institute of Civil Engineers in 1859, a member in 1873, a member of Council in 1884, a Vice-President in 1895, and President in 1900.

GENERAL NOTES.

TRADE WITH BOLIVIA.—In his report upon the trade of Bolivia for 1904 (3388, Annual Series), Mr. Consul Harrison says that British manufacturers would do well to send their catalogues in the Spanish language, indicating weights, measures, prices, discounts, and every possible detail, as is done by competing countries. Another step that should be taken by manufacturers of mining machinery and tools of every description is that of the establishment of depots or agencies at Oruro, the most important mining centre, and at Autofagasta, its port. It is also desirable that all machinery should be made in sections to facilitate the transport by mule back, as the roads in the country are very rough and hilly, and do not permit the traffic of carts. The weight of any package should not exceed 350 lbs. Vice-Consul Mr. E. F. Moore, writing upon the trade of the Sucre district, says it is impossible to over-estimate the value and importance of issuing catalogues, price lists, and pamphlets printed in Spanish, and, if possible, properly illustrated, to bring before the notice of a very conservative people new articles and modern types of all household use. "I frequently meet people," writes Mr. Moore, "in a position to buy who will not look at anything printed in English It is really diverting to see how the American patent medicine makers have literally imposed their goods by means of picturesque and really attractive advertisement sheets and other contrivances almost played out in the Old World. The lower classes decorate their rooms with these sheets, and have them before them until the article which they propose to bring before the consumer literally becomes a by-word."

TEA CULTIVATION IN JAVA.—Some months ago attention was directed in the *Journal* to the probability of Java becoming in course of time a serious competitor in the tea markets of the world, and Mr. Consul Fraser's report (3403, Annual Series) on the trade of the island in 1904 supports this view. The tea exports have more than doubled in the last ten years, from 12,841,720 lbs. in 1899 to 25,375 691 lbs. in 1904. Last year the exports were increased by over 3,000,000 lbs. as compared with 1903. A large area of new land has been laid out for tea cultivation with Assam seed, which insures a further increase of quantity to be disposed of in the near future. Of the exports in 1904 more than half, 13,102,916 lbs., went to the Netherlands, the United Kingdom taking 9,918,408 lbs. of the remainder, Russia, Singapore, and Australia taking nearly all the rest. A feature of the year has been the establishment of a tea market at Batavia, three firms having started business, while several of the local houses contemplate taking up the trade.

EXHIBITION OF PROCESS ENGRAVING.—The loan collection of examples of process engraving, comprising photogravure, photo-lithography, and kindred reproductions by means of photography, which has been on view for the past three months at the Victoria and Albert Museum, South Kensington, will be closed on Sunday, 25th instant.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JUNE 26... United Service Institution, Whitehall, S.W., 3 p.m. Mr. E. Ashmead Bartlett, "The Siege and Capitulation of Port Arthur."

Geographical, University of London, Burlington-gardens, W., 8½ p.m.

TUESDAY, JUNE 27...Hellenic, in the Rooms of the Society of Antiquaries, Burlington-house, W., 5 p.m. Annual Meeting.

Statistical, 9, Adelphi-terrace, W.C., 5 p.m. Mr. S. Rosenbaum, "A Contribution to the Study of the Vital and other Statistics of the Jews in the United Kingdom."

WEDNESDAY, JUNE 28...SOCIETY OF ARTS, John-street. Adelphi, W.C., 4 p.m. Annual General Meeting.

Church Crafts League, Church-house, Dean's-yard, S.W., 8 p.m.

Royal Society of Literature, 20, Hanover-square, W. 8½ p.m.

British Astronomical, Sion College, Victoria-embankment, E.C., 5 p.m.

THURSDAY, JUNE 29...Antiquaries, Burlington-house, W., 8½ p.m.

Journal of the Society of Arts.

No. 2,745. VOL. LIII.

FRIDAY, JUNE 30, 1905.

NOTICES.

H.M. THE KING OF SPAIN.

The Council of the Society having elected H.M. the King of Spain an Honorary Royal Member, H.R.H. the Prince of Wales, as President of the Society, graciously communicated to King Alfonso the fact of his election, and has now received from His Majesty the following letter of acceptance :—

MONSIEUR MON COUSIN :—Le plaisir que Votre Altesse Royale veut bien trouver à Me prier de faire partie de la Society of Arts, en qualité de Membre Royal Honoraire, n'est certes pas moindre que celui que j'éprouve en acceptant cette distinction.

Je me considère fortuné de pouvoir inscrire Mon nom sur les listes où figurent déjà d'autres si illustres, et surtout ceux de l'Auguste Père de Votre Altesse Royale, Sa Majesté le Roi Edouard VII. dont je viens de recevoir l'hospitalité généreuse, et de son Aïeul vénéré et éclairé le Prince Consort d'heureuse mémoire.

La sphère d'action choisie par la Corporation insigne dont Votre Altesse Royale m'ouvre les rangs m'est d'ailleurs bien connue. J'en approuve et admire hautement les travaux, et serai fier d'y appartenir sous la présidence de Votre Altesse Royale, à laquelle Je suis charmé de renouveler l'expression des sentiments d'amitié vive et sincère, avec lesquels je suis

Monsieur Mon Cousin
de Votre Altesse Royale
le Bon Cousin
(Signed) ALFONSO, Rex.

Au Palais de Madrid,
le 14 Juin, 1905.

A Son Altesse Royale le Prince de Galles.

CONVERSAZIONE.

The Society's Conversazione will be held, by arrangement with the Council of the Royal Botanic Society, in the Gardens of that Society, Inner-circle, Regent's-park, on Tuesday evening, the 4th of July, from 9 to 12 p.m.

The central portion of the Gardens only will be used. The Gardens will be illuminated with coloured lamps, and also by the Kitson Incandescent Oil Light. The Conservatory and the Club-house will be open.

The Reception, by Sir William Abney, K.C.B., F.R.S., Chairman, and the other Members of the Council, will be held at the entrance to the Conservatory, near the Broad Walk, from 9 to 10 o'clock.

An Exhibition of Growing and Cut Roses and other Flowers will be arranged in a marquee in the grounds by Messrs. W. Paul and Sons, of Waltham Cross.

A Selection of Music will be peformed by the String Band of the Royal Artillery in the Conservatory, and by the Band of H.M. Grenadier Guards in the Gardens, commencing at 9 o'clock.

Two performances of Selections from Pastoral Plays will be given in the Gardens by Mr. Patrick Kirwan's Idyllic Players at 9.30 and 10.45 p.m.

A concert and entertainment, including a scene from "The School for Scandal," will be given in the Club-house, from 10 to 10.45 p.m.

Light refreshments (tea, coffee, ices, claret-cup, &c.) will be provided.

Each member is entitled to a card for himself (which will not be transferable) and a card for a lady. These cards have now been issued. A limited number of tickets will also be sold to members of the Society, or to persons introduced by a member, at the price of 5s. each, if purchased before the day of the Conversazione. On that date the price will be raised to 7s. 6d.

Members can purchase these additional tickets by personal application, or by letter addressed to the Secretary at the offices of the Society, John-street, Adelphi, W.C. In all cases of application by letter a remittance must be enclosed. Each ticket will admit one person, either lady or gentleman, and must be signed by the member applying for it.

Tickets will only be supplied to non-members of the Society on presentation of a letter of introduction from a member.

PROCEEDINGS OF THE SOCIETY.

ANNUAL GENERAL MEETING.

The Annual General Meeting for receiving the Report of the Council, and the Treasurers' Statement of Receipts and Payments, during the past year, and also for the Election of Officers, was held, in accordance with the By-laws on Wednesday last, the 28th inst., at 4 p m., Sir WILLIAM ABNEY, K.C.B., D.C.L., D.Sc., F.R.S., Chairman of the Council, in the chair.

The SECRETARY read the notice convening the meeting, and the minutes of the last annual meeting.

The following candidates were proposed, ballotted for, and duly elected members of the Society:—

Allfrey, Edward W., 2, St. Michael's-chambers, Oxford.

Bardill, W., Hildon-house, Wantage, Berks.

Bell, Sir Hugh, Bart., Rounton-grange, Northallerton, and 95, Sloane-street, S.W.

Benn, Alfred William, Il Ciliegio, San Gervasio, Florence, Italy.

Bodine, Samuel T., Broad and Arch-streets, Philadelphia, Pennsylvania, U.S.A.

Boulding, Sidney, M.I.Mech.E., 28, New Bridge-street, E.C., and Elcombe, Alleyn-road, West Dulwich, S.E.

Britten, W. E. F., Fulcher's Atelier, Bourne, Lincolnshire.

Chesterton, Fred., Messrs. G. and A. Brown, Limited, 167, Hammersmith-road, W.

Evans, B. P., The Schools, Treharris R.S.O., Glamorgan.

Faulkner, Alfred Robert, Fairholme, Worple-road, Wimbledon.

Foster, Edward William Percival, C.M.G., 7 Rue des Ptolemées, Alexandria, Egypt.

Hamburger, Arthur, Remilly, Pendle-road, Streatham, S.W.

Hartfree, George Bertram, Ackenden-road, Alton, Hants.

James, C. Boucher, 552, Oxford-street, W.

Keys, Samuel, Star Encaustic Tile Company, Bluff-street, Pittsburg, Pennsylvania, U.S.A.

Knowles, Mrs. Marian, 24, St. Edmund's-terrace, Regent's-park, N.W.

Lal, Prof. Ganeshi, B.A., Kayestha Pathshala, Allahabad, India.

Leonard, Charles Henry Brandt, 18, Kensington-palace-gardens, W.

Macaura, Gerald Joseph, M.D., 4 Spring-bank, Bradford.

Macpherson, Archibald, 171, Auckland-hill, West Norwood, S.E.

Master, Lieut.-Colonel R. Chester, The Residency, Salisbury, Rhodesia, South Africa.

Miller, Sir James P., Bart., D.S.O., 45, Grosvenor-square, W.

Moore, Alfred Ernest, B.A., B.Sc., F.C.S., Escuela Regional, Corrientes, Argentine Republic.

O'Shaughnessy, Hugh Patrick, Executive Engineer, South Indian Railway, Trichinopoly, India.

Palumkote, Miss Baiai Limjibhoy, Grant-road-bridge, Grant-road, Bombay.

Philip, Joseph, Dalmore, Westpark-road, Dundee.

Potter, Edward C., The Rookery, Chicago, Illinois, U.S.A.

Reid, Ernest John, 7, Western-villas, New Southgate.

Sanford, Miss S. Ellen, The Holme, Clifton Hampden, Abingdon.

South, Ernest H., Warwickshire Estate, Hunyani River, Mashonaland, Rhodesia, South Africa.

Sykes, Oliver Wyatt, 303, Bow Bazar-street, Calcutta, India.

Tate, James C., c/o United Lankat Plantations Co., 2, Tokenhouse-buildings, E.C.

Thakado, Maung, K.S.M., Prome, Lower Burma.

Thoresby, Frederick, 1, Queen Victoria-street, E.C.

Tompkins, Engineer Commander Albert E., R.N., Royal Naval College, Greenwich, S.E.

Vaughan, James Christopher Mason, 27, Commercial-street, Hereford.

Vernon, William Henry, The Laurels, Livingstone-road, Birchfield, Birmingham.

Wadia, N. P. N., 16, Trebovir-road, Earl's-court, S.W.

Wilkins, Thomas Henry, 9 Dunedin-house, Basinghall-avenue, E.C.

Wills, Edward Chaning, M.A., F.C.S., Eastdown-house, near Barnstaple.

And as Honorary Corresponding Members:—

Hansen, Prof. Emil Chr., M.D., Copenhagen, Denmark.

Pictet, Raoul, Geneva, Switzerland.

Rontgen, William Conrad, Munich, Bavaria.

Thomson, Prof. Julius, Ph.D., M.D., For. Memb. R.S., Copenhagen, Denmark.

Van de Waals, Prof. R. J. D., Amsterdam, Holland.

The CHAIRMAN nominated Mr. THOMAS BURNS and Mr. JOHN HUME scrutineers, and declared the ballot open.

The SECRETARY then read the following

REPORT OF COUNCIL.

I.—The London Institution and the Society of Arts.

The most important matter relating to the interests of the Society itself which the Council have had before them during the past year was the proposal for an amalgamation between the Society of Arts and the London Institution. An account of the proposal is given in a memorandum which was printed by order of the Council in the *Journal* for the 31st of March last, but it may be desirable to put on record in this Report what the proposal really was, and what action the Council took.

The matter first came formally before the Council on November 21st last, when a letter was read from the Board of Managers of the London Institution stating that they had appointed a Committee to consider the proposal, and to confer with any Committee which the Council of the Society might appoint. The names of the two Committees are given in the memorandum above referred to, but the Council think it right to mention that they are specially indebted to the Lord Chief Justice for the active personal interest which he took in the matter. He attended all the meetings of the two Committees, and took an active part in the preparation of their Report.*

This Report recommended the amalgamation of the two Institutions into a single body, and suggested the terms upon which such an amalgamation might be arranged. It was proposed that the objects specified in the Charters of the two Institutions should be carried out to the full; that the Proprietors of the London Institution should become permanent members of the new Corporation, and that the powers they now possess of transferring or bequeathing their rights should be continued in perpetuity, but that they should be relieved from the annual payment of Two Guineas at which they are now assessed. Provision was suggested for the case of any Proprietors who preferred to resign, by providing that any such Proprietor might receive a sum of £25 in discharge of his claims, an amount which was understood to be much above the price at which shares have lately been sold. Life members of the Society of Arts would have become life members of the new Institution. Annual subscribers would have continued their membership on the same terms as heretofore. The Governing Body was to be formed in the first instance by a combination of the Society of Arts Council and the Board of Managers of the London Institution, provision being made for the election hereafter of a suitable Governing Body.

The Ordinary meetings of the Society of Arts were to be continued on the same lines as heretofore, and the Sectional meetings were also to be carried on. The Society's examinations were to be continued. The *Journal* of the Society, now in its 53rd annual volume, was still to be published, probably in an extended and enlarged shape. The lectures which are now held at the London Institution were to be continued, and it was suggested that by a judicious expenditure upon the fine library of the London Institution, it might be brought up to date, and a scientific library produced of the highest character. The maintenance of the circulating library was recommended, though it was considered that fresh purchases should be limited to works of a scientific and technical character. It was also suggested that scientific and industrial research might be carried out, as was formerly the case with the London Institution when its resources permitted. The Report discussed the question of a new building, which would afford for the members of the new Institution accommodation on a more extensive scale than is now provided by either of them.

It was thought also that certain other societies would be inclined to unite in a scheme for a large building providing independent accommodation, and it was known that several of the less wealthy London societies would gladly have availed themselves of offices which could readily have been provided in a building such as was contemplated.

It was originally thought that arrangements might be made for effecting the amalgamation by a surrender of the separate Charters and an application to the Crown for a fresh Charter: but on Counsel's opinion being taken it became evident that such a proceeding was not a possible one. No provision exists in the statutes of either body for winding up the Institution, and it appears certain that the Charter could only be resigned with the unanimous consent of every member of each Corporation. The Committee were, therefore, advised by Mr. R. J. Parker, whose opinion they sought, that the simplest and best way of carrying the amalgamation into effect was to promote a private Act for the purpose.

* This Report was not printed in the *Journal*, but copies were sent to members of the Society desiring them. Any member wishing to read the Report can be furnished with a copy.

It was believed that the scheme suggested provided fairly and liberally for the members of the two Institutions alike, that it would give to those composing the new body all that the members of either Institution had received, and something in addition, so that the advantage alike to the members of the London Institution and of the Society of Arts would be equal. The Report was in due course submitted to and approved by the Council of the Society and the Board of Managers of the Institution, His Royal Highness the President of the Society, without whose consent of course no action could be taken in the matter, also approved the proposal.

It was naturally expected that the scheme would be cordially accepted by the General Meetings of the two Institutions. But when it was propounded to a special General Meeting of the London Institution, it was, rather to the surprise of all who had been concerned in its preparation, received with a somewhat violent opposition. Objections were taken to the removal of the Institution from the City, and representations were made, which seemed to be accepted as the truth by at all events a proportion of the Proprietors, to the effect that the whole scheme was in the interests of the Society of Arts, and that the Proprietors of the London Institution were giving up a fine property to be applied to objects in which they had no interest, and dealt with by a body over which they had no control. Eventually no decision was arrived at at the meeting, but a Committee was appointed to confer with the Board of Managers.

As soon as the Council of the Society of Arts were apprised of the result of this meeting, they at once decided that a project of this nature could not be dealt with in the spirit with which it seemed to have been approached by those who opposed it, and that it was better to abandon the scheme, so far as they were concerned, rather than to attempt to force it through against even a minority of the Proprietors of the London Institution. They, therefore, passed the following resolution, which was published in the *Journal* of May 12th :—

"In view of the feeling which appears to have been aroused amongst some of the Proprietors of the London Institution with regard to the proposed amalgamation with the Society of Arts, and the consequent probable difficulties of effecting a harmonious fusion of the two Corporations into a single Institution, the Council of the Society of Arts have decided not to take any further action in the matter, and hereby discharge the Committee which, at the instance of the Board of Managers of the London Institution, they appointed to consider the scheme for amalgamation."

Although they had accepted the original proposal with a certain amount of hesitation arising from the fear that the successful work which the Society has now so long carried on might suffer from an attempt to occupy the much larger field covered by the London Institution and the Society of Arts together, they yet felt that an Institution such as was contemplated, sufficiently endowed and properly directed, might be of the greatest public service, and that London would be provided with a powerful organisation devoted to Science, Art, Literature, and Education, which ought to be able to hold its own with any similar Institution in any part of the world. But they thought that the successful foundation and maintenance of such an Institution demanded the harmonious co-operation of all concerned, and that it was better to remain satisfied with the present condition of the Society rather than to attempt to force against opposition, whether powerful or weak, whether judicious or ill-advised, so difficult and complicated an undertaking as the organisation of a new Institution of the importance desired. If as the result of a conference, which is presumably to be held between the Board of Managers of the Institution and its Committee, any fresh overtures should be made to the Society, they will always be cordially welcomed and carefully considered; but the Council do not propose to take any further action themselves, or to bring the matter formally under the consideration of a General Meeting of the Society.

II.—Ordinary Meetings.

In accordance with the usual practice, the Session was opened with an address from the Chairman of the Council, Sir William Abney. In his previous address Sir William had dealt with the question of Commercial Education and the examinations of the Society, and had made an estimate, based on the examination results of previous years, of the numbers of candidates who might enter in future years for these examinations. So far as Sir William Abney's anticipations have yet gone, they have been more than realised, for whereas he expected 21,400 candidates for the present year, the actual number of entries was 25,951. In his Address last November, he discussed

the general question of the relation of Societies and private Institutions to the State, and indicated certain departments of scientific work, now being carried out by private enterprise, which could be more effectively and better dealt with by the State.

The first regular meeting of the Society after the opening meeting was devoted to a paper by Mr. B. H. Morgan, on "The Systematic Promotion of British Trade." Mr. Morgan described to the Society a scheme he had devised for familiarising British subjects resident in the Colonies with the condition of British industries by means principally of an organised system of lectures to be delivered in colonial centres, dealing with the different branches of British manufactures, and pointing out the requirements of British trade.

In his paper on "The Canals Problem," read at the second meeting of the session, Mr. Arthur Lee dealt with a topic which has not infrequently been before the Society, and once more urged the importance of a consideration of the neglected waterways of the kingdom.

In the next paper Mr. W. F. Reid gave an interesting account of the British Section at the St. Louis Exhibition, and showed that the contributions of Great Britain, though not in all respects equal to its contributions to some of the former great International Exhibitions, were yet, as a whole, worthy of the country. Although the leaders of many branches of British industry hesitate to incur a certain expense for a problematic and inadequate return, it is yet satisfactory to know that in some departments at all events, especially that of Industrial Chemistry, the country was worthily represented. It is not a little remarkable that this department should be the one in which in previous exhibitions Great Britain has always made but a poor appearance. This was a proof of what has often been said of the necessity for co-operation amongst the exhibitors themselves. They are not quite ready to realise that it is less important that individual firms should make a good show than that the country should be well represented in any special branch of industry. The rewards of such exhibitions go not only to the individuals who have contributed to it, but also to the trade in general.

At the last meeting before Christmas another topic familiar to the Society was discussed, when Mr. C. D. Abel read a paper on "The Patent Laws," dealing especially with the new Act, which has since the 1st of January come into force. As the Society was largely interested in the movement which led to the first reform of the Patent Laws in 1852, and was mainly instrumental in bringing about the second important Act in 1883, any paper on this subject read at the Society of Arts naturally attracts a good deal of attention, and this was the case with the valuable contribution from Mr. Abel.

At the first meeting after Christmas a paper of very great interest was read by Captain Lionel James, who gave an account of his own attempts to organise, probably for the first and last time, a system of journalistic war correspondence by means of wireless telegraphy. The experience of Captain James, as the correspondent who reported to *The Times* the earlier performances of the Japanese in naval war, can hardly be repeated, for it is unlikely in the future that any such attempt to transmit news by wireless telegraphy will ever be permitted by naval combatants.

The paper which followed on "London Electric Railways," by the Hon. Robert P. Porter, was remarkable not only for the account it gave of the present condition and future prospects of such railways in London, but also for the great amount of information which Mr. Porter had collected about similar enterprises in other countries, especially in the United States, where the cities of New York and Chicago have in many respects set an example to London.

In the next paper Sir William Preece, who had been led in the course of a recent visit to Egypt to pay special attention to the navigation of the Nile, read a most interesting paper on that subject. The information supplied by Sir William Preece was usefully supplemented by the remarks of the Chairman of the meeting, Sir Robert Hanbury Brown, who is responsible for much of the work which has lately been carried out on the Nile.

The very popular subject of Photography was next dealt with by Mr. R. Child Bayley, whose paper was an account of the manner in which mechanical methods of time development have to a large extent superseded the older forms of photographic development. It is not a little strange that a scientific process, the success of which was for so many years considered to depend upon the personal skill and ingenuity of the operator, can now be carried out in such great perfection by purely mechanical means. Mr. Child Bayley's account of the methods by which these results

have been obtained appealed alike to the most skilful operators and to those who have been led to the practice of photography by the modern facilities for carrying it out.

Some original views as to the decline of the country town and the migration of the population into the great cities was put forward by Mr. A. H. Anderson in his paper on that subject, a paper which was the result of a good deal of careful and ingenious research. On the following Wednesday, Mr. J. E. Borland dealt with what he termed "Some Misconceptions of Musical Pitch." Mr. Borland dealt with the inconveniences of modern notation, the difficulties caused by the necessity for transposition in orchestral scores, and, generally, the desirability of adopting some more logical and sensible system than the one at present in use.

A reference has been previously made to the paper by Mr. W. F. Reid on the St. Louis Exhibition, so far as refers to the commercial side. This paper was most usefully supplemented by Mr. Isidore Spielmann, who gave a very full account of the British Art Section, a section in which this country admittedly held its own with any other, and one which contained probably the finest collection of pictures ever sent from Great Britain to any foreign exhibition.

At the next meeting, the Society was fortunate in hearing from an eminent Japanese some account of the ethics and morals of that remarkable country in the paper read by Baron Suyematsu on "The Ethics of Japan." It was not until the war was well in progress that much attention was drawn to the systems of Japanese morals by a very able article in *The Times*, and by some articles contributed by Baron Suyematsu himself to the *Nineteenth Century*, and some other magazines. Baron Suyematsu's paper, together with the articles referred to, may be said to have helped to teach the people of this country the true nature of the character of the Japanese, and helped to explain all their wonderful recent successes. At this meeting Lord Redesdale, who as Mr. Percy Mitford was the first to introduce the history of Japan to popular knowledge in his tales of "Old Japan," was in the chair.

In his paper on "Methods of Design in Mohammedan Art," Dr. E. H. Hankin put forward some new ideas as to the origin of the exquisite and complicated designs which form so principal a feature of Indian Mohammedan Art. Though some of the speakers in the discussion were not quite prepared to admit the full accuracy of Dr. Hankin's suggestions, they yet bore testimony to their value, and admitted the light they shed on this particular branch of decorative art.

Last year Sir Charles Kennedy read a most instructive paper on the Fiscal Question, and in a second paper read at the end of March last he brought this difficult question up to date. Sir Charles Kennedy's treatment of the subject, as was suited for the Society, was purely statistical, and he left on one side the thorny difficulties of Free Trade and Protection.

Of recent years the Society has had many valuable contributions on the subject of British Forestry, and very various views have been expressed by such authorities as General Michael, Dr. Schlich, and Mr. D. E. Hutchins. In his paper on "British Woodlands," Sir Herbert Maxwell dealt with the question from the point of view not of the expert, the forester, or the trader in timber, but of the landlord, and he endeavoured to impress on his audience and the public, as 150 years ago the Society endeavoured to impress it on the landowners of that date, the importance of growing timber in a scientific manner, and the profit to be derived from its cultivation.

Considerable interest was aroused some few years ago by the late Mr. Theodore Bent when he drew attention to the ancient remains which exist in South Africa, and the details of the ancient architecture of the great Zimbabwe in Rhodesia which Mr. R. N. Hall gave in his paper, were followed with great interest by those who heard the paper, and by many readers of the *Journal*.

In his paper on "The Industrial Resources of the State of Matto Grosso, Brazil." Mr. G. T. Milne drew attention to a country which, though it cannot be said to be little known, has yet never received the attention it deserves. The industrial resources of the interior of South America, both mineral and agricultural, are only now beginning to be realised, and Mr. Milne's able contribution to our very limited knowledge of the subject was therefore very welcome.

This brings the record of the Society's meetings for the session down to Easter. At the first meeting after Easter Mrs. Burton-Brown gave an instructive account of the recent excavations in Rome, and showed a number of photographs illustrating the work which has lately been done in the exploration of the Forum. In the following week Lord Mountmorres put on record the results of his recent journey in Central Africa up the Congo to its junction

with the Ubangi, then up the Ubangi and overland by a devious route, which touched the Uganda border, back to the Congo again. The accounts given of the different races with whom Lord Mountmorres came into contact are of very great interest. They were fully illustrated by photographs of the people and their abodes.

A valuable technical account of the "Uses of Wood Pulp in Paper-making" was given by Mr. S. C. Phillips, whose knowledge of this subject is perhaps unrivalled. The sources from which the main supplies come, and the method of their treatment, mechanical and chemical, were fully dealt with, and some useful statistics brought down to the latest date completed the paper.

At the last meeting of the Session Mr. Killingworth Hedges gave an account of the work of the Lightning Rod Committee, a body which was appointed a few years ago to bring up to date the work of the Lightning Rod Conference, the report of which was published in 1881. Since then a good deal has been learned about the action of lightning, and the results of this new knowledge, which are set out in detail in the Report of the Committee, were clearly and usefully summarised by Mr. Hedges, who had acted as Honorary Secretary of the Committee, and to whose exertions the Report was to a very large extent due.

III.—Indian Section.

In the thirty-seven years that have passed since the Indian Section was established, Secretaries of State, ex-Viceroys, and retired Commanders-in-Chief, have been amongst the distinguished men who, by presiding at its meetings, have shown their appreciation of the work systematically and continuously performed by the Society of Arts on behalf of our great Eastern Empire. To these statesmen, administrators and soldiers, must now be added an eminent Indian feudatory in the person of the Maharaja Sir Sayaji Rao, G.C.S.I., Gaekwar of Baroda. The occasion upon which for the first time an Indian reigning prince has taken the chair at a meeting of this or perhaps any other learned society in London was the reading by Mr. H. J. Tozer of not the least valuable of the series of papers jointly organised by the Indian and Colonial Committees, and dealing with a subject of acknowledged Imperial importance, namely, the manufactures of Greater Britain. The value of Mr. Tozer's comprehensive survey was enhanced by the fact that during a recent visit to India he spent some time in making himself personally acquainted with the existing industrial conditions in Calcutta, Bombay and other commercial centres. He demonstrated that while India more than any other portion of Greater Britain gives the Empire its imperial character, and may justly claim the first consideration after the United Kingdom itself, the "oft-predicted outburst of industrial activity" has not yet arrived, and that for a long time to come the manufacture of produce now exported raw will probably be the most fruitful sphere of effort. In the discussion, Sir George Watt, speaking from his special experience, maintained that the industries of India will never be able adequately to compete with European manufactures unless the present antiquated methods are abandoned, and development made on modern or European lines.

Early in the Session when the results of the Younghusband expedition were engaging much attention, Mr. Douglas Freshfield, the intrepid mountaineer, read a very interesting paper to a distinguished audience, on "The Gates of Tibet," as he aptly described the State of Sikkim. Numerous photographic views of the magnificent scenery of Sikkim were shown on the screen, and charmingly described by the author, who incidentally advocated the despatch of an exploring party down the Brahmaputra with the twofold object of solving certain geographical problems, and opening up the eastern extremity of Tibet.

Plague in its medical and technical aspects has frequently been treated, but in the able and elaborate paper contributed by Dr. Charles Creighton, the epidemic now raging with increased virulence in Northern India, was described from a more general standpoint. At the cost of the research fund, known as the Leigh-Browne Trust, the author of the well-known "History of Epidemics in Britain" went to India towards the end of last year for the purpose of learning something of the actual conditions of plague, and the paper read by him a few weeks after his return to England embodies the results of his painstaking and rather extensive inquiries. It also advanced certain theories as to the causes of plague in India, especially in the mud built villages of the plains, theories that were not entirely accepted by one or two of the scientific experts who took part in the full and useful discussion on Dr. Creighton's paper.

In the Session before last Mr. J. A. Baines

read a paper entitled, "Gleanings from the Indian Census of 1901," in which he treated, with his characteristic lucidity and skill, the statistics then available. The Census report itself "contained in three large quarto volumes besides about 60 subsidiary volumes for the different provinces" was issued last year, and by desire of the Committee Sir Charles A. Elliott contributed a paper at the earliest possible date on some of the more important points, ethnological, linguistic, &c., elucidated in the monumental record of the labours of Mr. Risley and his coadjutors. One of the latter, Dr. G. Grierson, was present at the meeting, and took part in the discussion on Sir C. Elliott's interesting and informing paper.

To the series of papers on the Provinces and Capitals of India, a welcome addition was made by Sir Frederic Fryer, whose authoritative description of the province of which he was the first Lieut.-Governor admirably supplements the paper on "British Burma under British Rule," given to the Society some years ago by his successor Sir H. Thirkell White.

Of the remaining papers, one by Sir J. George Scott was on "The Prospects of the Shan States," and the other by Mr. T. C. Hodson on "Manipur and its Tribes." Both may be regarded in a sense as complementary to the papers of Sir Thirkell White and Sir Frederic Fryer, and as forming, together with the paper on Assam given to the Society in 1903 by Sir Charles Lyall, a very complete account of the interesting States forming the north-eastern fringe of the Indian Empire.

IV.—Colonial Section.

The Session opened with a singularly able paper on "British Commercial Prospects in the Far East," by Mr. Byron Brenan, C.M.G., late H.B.M. Consul-General at Shanghai. For want of time and other reasons Mr. Brenan confined his remarks to China, and it is hoped that the other States forming what is known as the Far East will be dealt with later in an equally comprehensive manner either individually or collectively. Mr. Brenan showed that if we are to hold our own in China it is necessary that the British manufacturer must "wake up." Indeed he says, "It will require more energy than we are now displaying, and also a change of tactics, if we are to improve, I do not say only to the same extent but in the same ratio as the others." British firms, he tells us, grow less in number, and ur European competitors fill the gap. When a new opening presents itself the rival is quicker to seize the opportunity. Our share in new railway projects does not seem quite satisfactory; but Mr. Brenan considers that British capital can be best employed in the exploitation of China's immense mineral resources—when the Pekin authorities can be induced to redeem the promise they made to Sir James Mackay to introduce reasonable mining regulations. Not the least instructive portion of the paper was that in which Mr. Brenan discussed the probable effects of the present Russo-Japanese war on the commercial future of China.

Reference has been made above to the series of papers on "The Manufactures of Greater Britain." The original idea was to have one paper for the whole of the Empire beyond the seas. This, however, was found to be impracticable, and so it was decided to deal with the subject piecemeal. As already mentioned India formed the subject of one paper. The Dominion and the Commonwealth were also treated separately. The excellent Canadian paper was contributed by Mr. C. F. Just, a well-known London official of the Dominion Government, and the equally admirable Australasian paper by the Hon. Walter James, K.C., Agent-General for Western Australia, and formerly Premier of that colony. The preparation of these exhaustive papers involved great labour, and the Society is much indebted to the authors for the trouble they took in the matter. The Society has been officially requested to include the West Indies in the series, and the suggestion will be considered.

A paper on "The Cape to Cairo Railway" had been promised by Sir Charles Metcalfe for the concluding meeting, and had been anticipated by the members of the Society and their friends with considerable interest. It had, however, to be postponed at the last moment owing to the sudden indisposition of Sir Charles Metcalfe.

V.—Applied Art Section.

At the first meeting of the Section in December last, Mr. T. G. Jackson, R.A. read a valuable paper on "Street Architecture," in which he alluded to symmetrical design in street architecture as applied to towns generally, and the changes necessitated by the universal use of iron construction in the formation of shop-fronts. He then specially referred to the rebuilding of the Strand, between Wellington-street and the Courts of Law, and advocated

some change in the present frontage line, at the same time pointing out the great danger of allowing buildings to rise to such a height as to dwarf the proportions of the two churches which divide the road. There was an animated discussion on the whole question, and the discussion was continued in *The Times* and other newspapers.

At the second meeting, Mr. Edward Johnston and Mr. Graily Hewitt read two papers on "Calligraphy and Illumination." Both authors urged the advantages of special attention being drawn to the improvement of ornamental handwriting and a return to the best models of the past, showing that in art there was still room for the making of manuscript books which should be distinguished by clearness of lettering. In the discussion that followed the reading of the papers, the speakers generally agreed with the opinions of the authors, and those competent to express the opinion held that as printing at its invention owed everything to writing, so the art of type founding, which was constantly tending towards a fixed form, might be improved by attention being paid to the best pen-forms.

In his exhaustive paper on the Queen Victoria Memorial as compared with other royal memorials abroad, Mr. Marion Spielmann passed in review a fine collection of views of the chief royal memorials of the world, and then explained the plan of the Queen Victoria Memorial in the Mall of St. James's Park, and illustrated it by views of the architectural design of Sir Aston Webb, R.A., and the sculptures by Mr. Thomas Brock, R.A. Mr. Spielmann explained that it was feared want of funds would prevent the whole of the grand scheme of the Processional Road from being carried out.

Mr. F. Bligh Bond, in an interesting paper on "West Country Screens and Rood Lofts," gave a full description of these remarkable architectural ornaments which are so frequent in the churches of Devonshire. In the discussion, reference was also made to the fine screens in the Eastern counties, and the question was raised as to whether the workmanship was due to foreign or English craftsmen. Mr. C. E. Keyser contributed a series of coloured illustrations of saints' and other figures on the church screens of the country.

Mr. Starkie Gardner's historical paper, "Monumental Treatment of Bronze," was in continuation of a former paper on the same subject. In 1888 he dealt with sepulchral monuments, and in the present one he treated of equestrian statues and bronze doors, illustrated by an important series of views of the finest Italian monumental art. The early doors, of which a large number of representations were shown, consisted of small panels. The famous artist, Ghiberti, was the first to abandon the strongly constructional form and introduce larger panels, a fashion generally adopted, so that frequently the great gates of the later period were made up of only three panels to a leaf.

The last paper of the Session was that on May 20th, by Mr. H. R. Hall, on "The Excavation of the Oldest Temple of Thebes."

The second temple at Deir el-Bahari, which is now being excavated by Professor Naville, under the auspices of the Egyptian Exploration Fund, stands side by side with the first temple excavated some ten years years ago by him. This second temple is a thousand years older than the first discovered temple, and dates from the time of the Eleventh Dynasty (about 2500 B.C.). Mr. Hall, who has taken part with Professor Naville in the excavation during the last two seasons, gave a fully-illustrated account of the course of proceedings by which this important work has been successfully carried out.

VI.—Cantor Lectures.

The first course of Cantor lectures was on "Musical Wind Instruments," by Mr. D. J. Blaikley. Mr. Blaikley, who is connected with the well-known firm of Boosey and Co., is recognised as an authority on the subject, and his lectures were well attended by many who were specially interested in it. His own practical skill as a performer enabled him to give many illustrations on various instruments, but he also secured the assistance of several well-known performers who provided illustrations in solo and concerted music. The lecturer dealt very thoroughly with the subject, beginning with an explanation of the acoustical principles on which all wind instruments depend for their action, and in the following lectures describing the three classes into which all wind instruments may be divided—brass, reed, and flutes.

In the second course, Mr. J. P. Maginnis gave a very full and detailed account of the various inventions which have resulted in the production of modern stylographic and fountain pens. Few who use this now popular instrument can have any idea of the amount of ingenuity which has been devoted to its development, or of the attention, as exemplified by the number of patents which have been

taken out, which has been given to it, until it assumed its present finished shape.

Mr. Dugald Clerk's course on "Internal Combustion Engines" attracted a large and interested audience of students of engineering, who appreciated to the full the accurate and thoroughly scientific account of the modern gas engine and its congeners which the lecturer provided. A very similar audience attended Mr. H. L. Webb's lectures on "Telephony." Mr. Webb described the instruments, apparatus, and plant required for a telephone system, and in his last lecture discussed such general questions as rates, tariff, demands of consumers, development in various countries, and long distance service rates.

Mr. Alan Cole, to whom the Society has indebted for many valuable lectures and papers on lace and needlework, gave two very attractive lectures on "Some Aspects of Ancient and Modern Embroidery."

The last course of the Session was delivered by Mr. H. W. Ravenshaw, and dealt very completely with "The Uses of Electricity in Mines," a development which, in the opinion of many competent to judge, is likely to revolutionise the practice of one of our greatest industries.

VII.—Juvenile Lectures.

For the Juvenile lectures of the present Session the Society were indebted to their Treasurer, Mr. Carmichael Thomas, who utilised the experience he has gained by his long connection with *The Graphic* and *The Daily Graphic*, in the preparation of two lectures on "The Production of an Illustrated Newspaper." Dividing his subject into two, Mr. Thomas devoted his first lecture to the production of the material of a newspaper—news and illustrations; while his second lecture described the general production of a modern illustrated newspaper of the very highest class.

VIII.—Albert Medal.

The Council have awarded the Albert Medal for the present year, with the approval of His Royal Highness the President, to the Right Hon. Lord Rayleigh, O.M., D.C.L., Sc.D., F.R.S. "In recognition of the influence which his researches, directed to the increase of scientific knowledge, have had upon industrial progress, by facilitating, amongst other scientific applications, the provision of accurate electrical standards, the production of improved lenses, and the development of apparatus for sound signalling at sea."

The Council have been glad to recognise once more the importance of pure scientific research in its effect upon industrial development. For many years past Lord Rayleigh has devoted his life to long-continued and patient research into the various branches of physical science. There can be hardly any branch of physics to which Lord Rayleigh has not contributed valuable knowledge. The important work which has been accomplished by various Committees, National and International, in formulating electrical standards and methods of electrical measurement has been to a very large extent founded upon Lord Rayleigh's researches. His investigations into optical science have had a marked influence in the construction of recent lenses, photographic and telescopic. He was the first to calculate the extent to which the definition of a spectroscope depends upon the actual thickness of the prisms, and this was applied later to the defining power of lenses; and while the improvement in modern lenses is largely due to the work of others than Lord Rayleigh, especially to those who have provided the lens-maker with glasses of high refractory powers, it is certain that the form which all photographic lenses now possess has been affected by his researches. Lord Rayleigh has been for some years past the Scientific Adviser of the Trinity House, a post in which he succeeded the late Professor Tyndall, and this led him to devote his scientific knowledge to practical investigations of his own, and he was thereby enabled to introduce several important improvements in the construction of apparatus for sound-signalling at sea. He is also Chief Gas Examiner in the metropolis, in which position his scientific training has proved of the utmost value.

His scientific work is of course outside the purview of the Society; but as evidence of his patient labours it may be worth mentioning that from the year 1869 until the present date he has written and published more than 270 papers, no less indeed than nearly eight for every year.

IX.—Medals.

The Council have awarded the Society's Silver Medal to the following readers of Papers during the Session 1904-5:—

At the Ordinary Meetings:—

To Mr. Arthur Lee, J.P., for his paper on "The British Canals Problem."

To Mr. CHARLES DENTON ABEL, for his paper on "The Patent Laws."

To CAPTAIN LIONEL JAMES, for his paper on "Wireless Telegraphy and War Correspondence."

To the HON. ROBERT P. PORTER, for his paper on "London Electric Railways."

To Mr. R. CHILD BAYLEY, for his paper on "Time Development in Photography, and Mechanical Methods of Carrying it Out."

To BARON KENCHO SUYEMATSU, B.A., LL.M, for his paper on "Ethics of Japan."

To Dr. E. H. HANKIN, for his paper on "Methods of Design in Mohammedan Art."

To the RIGHT HON. SIR HERBERT MAXWELL, Bart., M.P., for his paper on "British Woodlands."

To Mr. GEORGE TORRANCE MILNE, F.R.G.S., for his paper on "The Industrial Resources of the State of Matto Grosso, Brazil."

To VISCOUNT MOUNTMORRES, for his paper on "The Native Races of the Unknown Heart of Central Africa."

In the Indian Section :—

To Mr. T. C. HODSON (late I.C.S.), for his paper on "Manipur and its Tribes."

To SIR J. GEORGE SCOTT, K.C.I.E. ("Shway Yoe"), Superintendent and Political Officer, Southern Shan States, for his paper on "The Prospects of the Shan States."

To Dr. CHARLES CREIGHTON, M.D., for his paper on "Plague in India."

In the Colonial Section :—

To Mr. BYRON BRENAN, C.M.G., for his paper on "British Commercial Prospects in the Far East."

To Mr. C. F. JUST, Canadian Government Service in London, for his paper on "The Manufactures of Greater Britain.—I. Canada."

To the HON. WALTER HARTWELL JAMES, K.C., Agent-General for and late Premier of Western Australia, for his paper on "The Manufactures of Greater Britain.—II. Australasia."

In the Applied Art Section :—

To Mr. THOMAS GRAHAM JACKSON, R.A., for his paper on "Street Architecture."

To Mr. F. BLIGH BOND, F.R.I.B.A., for his paper on "West Country Screens and Rood Lofts."

Two years ago it was decided that no medal should be awarded to readers of papers who had previously received medals from the Society. Acting on this rule the Council were precluded from considering the following papers :—At the Ordinary Meetings, the paper by Sir Charles Malcolm Kennedy, K.C.M.G., C.B., on "The Present Aspect of the Fiscal Question." In the Indian Section the paper by Mr. Henry John Tozer, M.A., on "The Manufactures of Greater Britain.—III. India," and that by Sir Charles Elliott, K.C.S.I., on "The Indian Census of 1901." In the Applied Art Section the paper by Mr. J. Starkie Gardner, on "The Monumental Treatment of Bronze." All these papers the Council consider to be of considerable merit and well worthy the distinction of a medal.

The thanks of the Council were also voted to Sir William Preece for his paper on "The Navigation of the Nile," the Council always feeling themselves debarred from awarding medals for papers read by members of their own body.

X.—OWEN JONES PRIZES.

After the death, in 1874, of Owen Jones, a committee was formed to collect subscriptions for the purpose of founding a memorial. The money thus obtained was partly expended in erecting a monument over his grave in Kensal Green, and the balance (a sum of £400) was presented to the Council of the Society of Arts upon condition of their expending the interest thereof in prizes to "Students of the Schools of Art who, in actual competition, produce the best designs for Household Furniture, Carpets, Wall-papers and Hangings, Damask, Chintzes, &c., regulated by the principles laid down by Owen Jones." The prizes have now been awarded annually since the year 1878 on the results of the annual competition of the Board of Education.

Six prizes were awarded this Session, each prize consisting, in accordance with the regulations laid down for the administration of the Trust, of a bound copy of Owen Jones's "Principles of Design," and a Bronze Medal.

The list of the successful candidates has already appeared in the *Journal*.*

The next award will be made this summer, on the result of the present year's examinations. Six prizes have again been offered for competition.

XI.—NORTH LONDON EXHIBITION TRUST.

In 1865 the Committee of the North London Working Classes and Industrial Exhibition (1864) presented to the Society of Arts a sum of £157, the balance of the surplus from that exhibition, with a view to the award annually of prizes for the best specimens of skilled workmanship exhibited at the Art Workmanship Competitions of the Society of Arts. The Art

* See *Journal*, vol. lii, p. 809, 23 September, 1904.

Workmanship Competitions were discontinued after 1870, and it has since been rather difficult to know how the funds arising from the Trust could be disposed of in a manner which might accord with the intention of the donors. In 1884 the Society awarded certain prizes in connection with the Inventions Exhibition, and among these was one (a gold medal or £20) offered under the Trust in question for the best set of specimens illustrating the handicraft teaching in any school. In 1896 an amount of £22 odd was awarded in prizes at the East London Exhibition, held in that year. There was in 1902 a small accumulation of the interest on the invested capital, and the Council decided that a very proper way of disposing of the available amount would be to offer it in art workmanship prizes for students connected with that part of the metropolis where the North London Exhibition was held. They, therefore, offered prizes for Art Workmanship amounting to Fourteen Guineas (a First Prize of £7 7s., a Second of £4 4s., and a Third of £3 3s.), to students in the Art classes of the Northampton Institute, Clerkenwell.

The prizes were duly awarded in November, 1903, and as the result of the competition appeared satisfactory, the offer was renewed for the following year, with the result that three prizes as before were awarded to successful students in the Artistic Crafts Department of the Institute.*

XII.—Prize for a Dust-Arresting Respirator.

It was announced in the last Annual Report that the Council were prepared to award under the terms of the Benjamin Shaw Trust a Prize of a Gold Medal, or Twenty Pounds, for the best Dust-Arresting Respirator for use in dusty processes, and in dangerous trades, and it was stated that the Committee appointed to consider the apparatus sent in had had before them inventions from 60 different inventors, of which 27 came from the United Kingdom, and 33 from other countries, viz., United States of America (9), Germany (6), Austria (6), France (3), India (2), Italy (2), Norway (2), Holland (1), Canada (1), Tasmania (1).

The final report of the Committee was received by the Council in May last, and was published in the *Journal* of June 9th. The report, while appreciating much of the apparatus which had been submitted to the Committee, found that none of them were sufficiently effective, or sufficiently original, to justify the award of the prize. The Committee stated that they had evidence before them showing that many of the apparatus submitted had been of great practical service, and they added that they recognised the efficiency of masks, even of quite a simple character, in protecting workpeople to a certain extent from various dusts. What, however, was wanted was something decidedly superior to any of the well-known masks now in use. It was hoped that the offer of a prize might produce such an apparatus, but this it has failed to accomplish. They continued, however, to recommend the problem to inventors, and they gave some notes on the apparatus which they had investigated, which they hoped might prove useful both to the inventors referred to, and to others who are endeavouring to solve a very difficult but important problem. While it appears to be rather too sanguine to hope that any device will be produced which can be satisfactorily and easily worn by a man doing hard physical work, there is no reason why a mask should not be made which would be effective in keeping out dangerous dust, without being so extremely inconvenient in use as quite to deter workpeople from its use. However efficient a respirator may be, it must to a certain extent impede breathing and must be more or less warm. The problem is to produce a piece of apparatus with a maximum amount of protection, and with a minimum amount of inconvenience.

In accepting the report of the Committee, the Council desire to express their disappointment that they were not able to find anything deserving the award, and to say that they will be always ready to renew the offer, if there seems any probability of such an offer producing any fairly satisfactory result.

The Council also desire to record their appreciation of the trouble taken by Mr. H. H. Cunynghame on behalf of the Committee, of which he acted as Chairman.

XIII.—Prizes for Drawing.

Since 1889, the Council have annually placed at the disposal of the Royal Drawing Society, for competition among the candidates at its annual examination, 12 Bronze Medals, and these medals were awarded for drawings sent

* The following are the names of the successful students:—1903: First Prize, A. J. Downey; Second, S. F. Briault; Third, F. C. Latter. 1904: First Prize, E. A. Halfull; Second, L. E. Stanton; Third, F. Cockren.

in by students to the exhibition held by the Drawing Society in April last.

XIV.—EXAMINATIONS.

The great increase in the number of candidates at the Society's examinations has rendered it impossible to bring the returns to such a state as to enable the usual detailed review of them to appear in the present report. It is, therefore, only possible to give here a general summary of the work which has been done, and to leave the publication of details until a little later. The Council, however, are able to state that the alterations which were made this year in the examination system have been thoroughly successful, and appear to have met with the approval and appreciation of all concerned. The members will remember that instead of the old system of two grades—a general and an elementary—there are now three Stages—(1) Elementary, (2) Intermediate, (3) Advanced, the alteration having been made in consequence of the suggestions which have for some years past been made to the Council that it was desirable to establish a rather higher grade of examination, which might be taken by more advanced students than those generally entering for the Society's examinations. The Elementary Stage is the same in every respect as the Elementary Grade, which was first established in 1901. There has really been no change in it, except in its title. The old Grade II. was divided into two parts—Intermediate and Advanced. Candidates who had not previously passed in the Society's examinations, were recommended to enter in the first instance for the Intermediate Stage, while candidates who had already passed a Second or Third-class of Grade II., and had made progress, were expected to be able to take the Advanced Stage.

As a result, 8,427 papers were worked in the Elementary Stage, 10,534 in the Intermediate, and 4,842 in the Advanced. The total of all these, 23,803, is a very large increase on the total numbers for 1904, which in itself was higher than any previous year. But, except as regards the Elementary Stage, a detailed comparison of the results is precluded by the alteration in the system. The percentage of failures in the Advanced Stage is about a third, which may be taken as showing that on the whole not a very large proportion of insufficiently prepared students entered for this stage, and this is satisfactory. In the Intermediate Stage the percentage of failures is a little less (about 32 per cent.). It is satisfactory to note that of the subjects added to the Advanced Stage a considerable number (208) entered for Accounting and Banking, and 169 for Commercial Law. The other new subject, Hindustani, only attracted two candidates in the Intermediate Stage and none in the Advanced. Japanese, which has been on the list for a good many years, has for the first time attracted a few candidates. It is to be hoped that they are the precursors of a larger number in future years. As soon as the results are known with sufficient accuracy a summary of them will be given in the *Journal*, with such remarks upon the different subjects as may seem desirable.

XV.—VIVA VOCE EXAMINATIONS IN MODERN LANGUAGES.

These examinations, which were established in 1902, are, it is satisfactory to be able to remark, attracting an increasing number of candidates. Up to the present date 15 examinations have been held this year in London and in Manchester. Arrangements have also been made for holding examinations at several other centres.

At these examinations 386 candidates presented themselves, of whom 296 passed (48 with distinction) and 90 failed. The languages taken up were as last year, French, German, Spanish, and Portuguese. Italian has been added, but as yet no examination has been held in that language.

The results of previous years are as follows:—

Year.	Number Examined.	Passed.	Failed.
1902	280	202	78
1903	456	324	132
1904	540	375	165

These examinations are held at any of the Society's centres where the necessary arrangements can be made. They are held at any date convenient to the local committee. The examination includes dictation, reading, and conversation, and the examination is so arranged as to test efficiency in a colloquial knowledge of the language, without laying too much stress on minute grammatical accuracy. Candidates who are reported upon as highly qualified by the examiners, receive a certificate of having passed with distinction.

The examiners are Mr. E. L. Naftel for French, Professor H. G. Atkins for German, Professor Ramirez for Spanish, and Mr. J. d'Oliveria e Silva for Portuguese.

* A Table giving details of the results was published in the *Journal*, of the 23rd June, vol. liii., p. 837.

XVI.—Practical Examinations in Music, 1904.

The practical examinations in Music were not concluded last year until too late a date for the results to be included in the Report of the Council.

The examination was conducted as usual by Mr. Ernest Walker, M.A., Mus.Doc.Oxon, and Mr. Burnham Horner.

The system of examination was the same as that for recent years. For instrumental music certain standards are given, and candidates are asked to select for themselves which of these standards they choose to be examined in. The standards range from easy to very difficult music. For each standard a list of music is given for study, and from this list candidates select the pieces they will sing or play. Candidates are expected to play or sing the pieces which they have prepared, to play or sing a piece, or portion of a piece, at sight, and to play certain scales.

In all, 578 candidates entered, and of these 557 were examined, an increase of 71 as compared with last year. This is the greatest number of entries yet received for these Examinations, the previous highest being 566 in 1901. There were 407 passes and 150 failures.

The following were the subjects taken up:—Piano, singing, violin, violoncello, and viola. 466 entered for the piano, 342 of whom passed; 68 entered for the violin, of whom 52 passed; 2 entered for the violoncello, both of whom passed; 20 entered for singing, of whom 10 passed; 1 entered and passed for the viola. No medals were awarded.

XVII.—Practical Examinations in Music, 1905.

The Practical Examinations for the present year have not yet been concluded. They commenced on Tuesday, June 20th. They will be finished about July 5th, after which a summary of the results will be given in the *Journal*. The work of the examination is being carried out by the same examiners as in the last five years. 437 candidates have entered for the present examinations, a decrease on last year of 139.

XVIII.—Leather for Book-binding.

The Council regret that they are not yet able to announce the publication of the revised edition of the Report of the Committee on Leather for Book-binding. Various circumstances have led to a rather unexpected delay in its completion. It is, however, now practically finished, and almost ready for publication. The final corrections of the text are in the printer's hands, the coloured illustrations—eleven in number—have all been printed, and there is nothing remaining which ought to cause any further delay. The coloured illustrations include a frontispiece showing the effect of decay in leather-bound books, which has been admirably reproduced from the actual books by Messrs. Sanger Shepherd and Co., eight plates showing the effect on leather, dyed with various materials, of light and other injurious agencies, and two illustrating the effect of sunlight on various dye stuffs when applied to leather. These last have been excellently reproduced from the originals by the colour-type process of Messrs. Carl Hentschel, Ltd. There are also a number of pictures in the text illustrating the method of binding recommended by the Committee, and others showing the effect of strain upon various leathers. Some specimens of dyed leathers will be mounted in the covers of the book.

XIX.—Exhibition of Photogravure.

In the year 1899, an exhibition of lithography was held at the Museum, now named the Victoria and Albert Museum, by the Science and Art Department, at the instance of the Council of the Society. This exhibition, intended in the first instance to commemorate the invention of lithography by Aloys Senefelder in 1798, was very complete, and proved extremely popular.

In the following year, 1900, the Council suggested to the Board of Education that an exhibition should be held to illustrate the progress which had been made during the past forty years in the typographical reproduction of drawings for book illustration; the proposal was adopted, and this exhibition, which was held in 1901, also proved attractive and instructive.

The success of these two exhibitions induced the Counnil of the Society to suggest, in 1902, that the series should be completed by the holding of an exhibition comprising the various methods of illustration which have not been dealt with in the previous exhibitions, viz., engraving, photogravure, and the various photographic processes other than those applicable to typographical work. In the opinion of the advisory committee, to which this proposal was referred, it was of too wide a scope for it to be adequately treated in a

single exhibition, and they therefore recommended the Board of Education to divide the proposal into two, to hold an exhibition of engraving and etching alone, and to defer to a later period the holding of an exhibition which might illustrate the various applications of photography other than typographical.

The Board adopted this modification of the original suggestion, and accordingly arranged in 1903 an Exhibition of Engraving and Etching, consisting of examples of copper and steel engraving, including line, mezzotint and stipple (plain and coloured), aquatint and etching.

In December, 1903, the Board of Education informed the Council that they proposed to hold another exhibition, to comprise the remainder of the scheme suggested by the Council to the Board in 1902, and that the exhibition would include photogravure and other photographic processes, including printing in colours.

This Exhibition was successfully opened in March last. It includes a Historical collection, illustrative of the progress of the Art, a collection of Foreign work, and one of British examples. The processes represented include Photo-engraving (under its various names—photo-mezzotint, papyro-type, photo-etching, heliogravure, autogravure, photogravure, &c.), Photo-lithography, Photo-zincography, Collotype, Woodbury-type, and Three-colour process work.

This series of four exhibitions, carried out with great completeness by the Board of Education, on the initiative of the Society, covers the whole range of Graphic Art as applied to reproduction. It has certainly proved extremely popular, and it has, the Council hope, also been sufficiently useful to students to justify the Board for its outlay, and for the great trouble that its officials have taken in so efficiently carrying into effect the suggestions laid before them.

XX.—Journal Indexes.

In 1902, the 50th volume of the *Journal* was completed. The indexes for the 10 yearly volumes—Nos. 41 to 50—were amalgamated, and issued last July as the fifth 10-Volume Index to the Society's *Journal*. Notice was duly given in the *Journal*, and a copy of the index was forwarded to all members who applied for one. The previous 10-volume index for volumes 31 to 40 of the *Journal* is in print, and can be supplied to any members who require it.

XXI.—The Portrait of Sir Frederick Bramwell.

In November last, Mr. H. Graham Harris, lately a Vice-President of the Society, and for many years the late Sir Frederick Bramwell's partner, presented to the Society a portrait of Sir Frederick, specially painted for the purpose by Mr. Seymour Lucas, R.A. The portrait was a posthumous one, and consequently could only be executed from such materials as could be supplied in the way of photographs, painted portraits, &c.; but nevertheless, it is in the opinion of all who have seen it, an excellent likeness as well as an admirable work of art. In accepting it on behalf of the Society, the Council passed a resolution thanking Mr. Harris and expressing their appreciation of Mr. Seymour Lucas's work. A photogravure of the picture was issued as a supplement to the *Journal* of the 20th January last.

XXII.—List of Members.

The number of life and subscribing members on the Society's books is 3,722, this includes a few Institutions in Union who subscribe from their own funds. The number of new members elected during the year was 442; the losses by death and resignation amounted to 326.

During the last thirty-five years the number of the Society's members has not varied within very wide limits. In 1870 there were a little over 3,200; this rose in 1875 to 3,800. The numbers fell to 3,300 in 1881, and rose again to 3,656 in 1885. By 1899 the numbers had fallen to 3,078, rising again in 1900 to 3,123. Since then there has been a continuous increase up to 3,722 at the present time. In 1850 the numbers were a little under 2,000. The increase in the twenty years succeeding 1850 was doubtless due principally to the great exhibitions of 1851 and 1862. The number of Institutions in Union was much larger before the Examinations were thrown open. There are now in all only 22 Institutions in Union with the Society. Thirty-five years ago there were about 150.

XXIII.—Honorary Royal Members.

Under the provision of the Bye-laws, which authorise the Council every year to elect a certain number of life members of the Society, the Council have this year elected His Majesty the King of Spain as an Honorary Royal Member of the Society. His Royal Highness the President was good enough to communi-

cate his election to His Majesty, and His Majesty has accepted the election.

XXIV.—New Council.

The Vice-Presidents retiring this year are the Lord Chief Justice, Sir George Birdwood, Sir Charles Fremantle, the Lord Chancellor, and Lord Rothschild. The Lord Chief Justice has been nominated by His Royal Highness the President for election as a Vice-President, so that the number of Vice-Presidents will be increased from 22 to 23. To fill the vacancies the Council propose Sir William Crookes, the eminent physicist, who received the Albert Medal of the Society in 1899, Dr. Francis Elgar, who has served since 1901 as a Member of the Council, the Earl of Onslow, Sir Owen Roberts, who has been the Society's Treasurer for the past four years, and Mr. W. T. Shaw, who was the author of the proposal that the Society of Arts and the London Institution should be amalgamated.

The Members of Council retiring are Dr. Elgar, who, as above stated, is proposed as a Vice-President, Mr. H. H. Cunynghame, Sir Gilbert Parker, and Viscount Ridley. In their places the Council recommend Mr. Michael Carteighe, Mr. W. C. Knight Clowes, Mr. Henry Graham Harris, and the Hon. Richard Clere Parsons. All these, except Mr. Clowes, have served on the Council before, and have given constant attention to its work. Mr. Clowes, who is the head of the eminent firm of printers bearing his name, is an old member of the Society, and his family have been connected with the Society for a great many years past.

In place of Sir Owen Roberts, who retires from the office of Treasurer, the Council recommended Sir George Birdwood, whose long and energetic work on behalf of the Society is well known to the members.

XXV.—Conversazione.

The Society's annual Conversazione will be held on Tuesday next, the 4th July, at the gardens of the Royal Botanic Society. This is the fifth year in succession for which the gardens have been placed at the disposition of the Society of Arts. In previous years the entertainment has been very successful, and the Council trust that the Conversazione next Tuesday may be attended by a large number of the members and their friends. The arrangements will be of the usual character.

XXVI.—Obituary.

Sir Erasmus Ommanney, who died in December last, at the great age of 90, had been a member of the Society of Arts for more than 40 years, and was a member of the Council from 1870 to 1887. He was the first Chairman of the African Section when it was founded in 1874, and was a frequent attendant at the Society's meetings, retaining his interest in the Society's work until within the last year. A still older member of the Society was Sir Lowthian Bell, who joined it in 1859. He served for some years on the Council, and in 1895 he received the Albert Medal. Major-General Webber, who joined the Society in 1874, served on the Council with intervals from 1878 to 1884. He read several papers before the Society, and took an active part in the work of some of its committees. Sir John Simon became a member in 1876, and held the office of Vice-President in 1877-1878. Dr. Vivian Poore gave the Society a valuable course of Cantor Lectures on "Climate in its Relation to Health" in 1885. Mr. G. J. Morrison read an interesting paper on Maps and Charts in 1903, and for it he received the Society's Silver Medal. Dr. Isaac Roberts, the distinguished astronomer, had been a member of the Society of Arts since 1874, but never took any active part in its work. Another distinguished astronomer, Mr. Frank McLean, had been a member of the Society since 1861. Mr. Frederick Elkington, who had been a member since 1859, was closely connected with the early development of electro-plating, and the development of the firm bearing his name was largely due to him. Mr. Van Oven, who devoted himself to the improvement of the condition of the deaf and dumb, was a member of the Society of Arts since 1867, and an occasional contributor to its *Journal*. Mr. William Paul, the well-known horticulturist, who joined the Society in 1880, read a paper in 1889 on "Fruit Culture in England."

Among other members of the Society, of whom obituary notices will be found in the columns of the *Journal*, may be mentioned Colonel Sebastian Smith, Sir John Cutbbertson, Sir George Cotton, Sir David Tennant, General Cooke, and Sir John Barrant.

XXVII.—Finance.

The annual statement of receipts and expenditure was published—in accordance with the usual practice—in the *Journal* last week. It shows the revenue and expenditure for the financial year ending May 31st last, the Assets and Liabilities of the Society, its Investments and the Trusts standing in its name.

Among the receipts of the year is included a legacy of £250 left to the Society under the will of the late Mrs. Begley. Mrs. Begley, who died early this year, was elected a member of the Society in 1880. The Council have much pleasure in recording this appreciation of the Society's work on the part of one of its members.

The Statement shows that the finances of the Society are in a thoroughly sound condition, as has been the case for many years past. The invested property of the Society has shown a steady increase during the past thirty years, having grown from about £3,000 to over £21,000. This is exclusive of Trust Funds under the Society's control amounting to a little over £14.700.

The CHAIRMAN, in moving the adoption of the report, said he thought the members would feel satisfied with the work which had been done during the past year. The papers had been exceptionally good, and the finances of the Society were all that could be desired. Some of the papers he thought would prove to be historical and of lasting value. He felt sure the Society would approve of the action of the Council in awarding this year's Albert Medal to Lord Rayleigh, whose patient investigations into theoretical science had had a marked influence on applied science. Referring to the report of the Committee on Dust-Arresting Respirators, he regretted that the Committee had not been able to award the prize offered, but he thought they would have to wait a little time yet until something was produced which would solve the problem. The continued increase in the examinations he considered was becoming a question of very serious importance to the Society. The number of candidates had increased more than he anticipated; but he thought a proportion of the increase this year was due to the additional Stage which had been instituted, and that the rate of increase next year would be more normal than it has been in the present year. He referred to the Exhibition of Photogravure which has been held this year by the Board of Education at the Victoria and Albert Museum, and said it had been a great pleasure to him to act as Chairman of the Committee for the Exhibition. The Exhibition had shown the great progress which had been made in this country, particularly in colour photography and process work, although, speaking from a practical point of view, he thought there was a great deal of room for improvement in the composition of the colours used. There was a great lack of precision in the colours, and the colours which would be most efficient in use had proved not to be permanent. The question of the fading of colours, particularly dye-stuffs, required very careful investigation, and he hoped that chemists would take the matter up, and supply the manufacturers with colours which were tolerably permanent. With regard to the proposed amalgamation of the Society of Arts and the London Institution, he felt sure the members would be sorry that the negotiations had been brought to a close in the way they had. The Council had hoped that the matter would have gone through without any friction, as the benefits which would have accrued to the members of the Society would have equally accrued to the proprietors of the London Institution. He thought it a great pity that two flourishing institutions were unable to find some means by which they could amalgamate, and so more than double their powers of usefulness.

Mr. ADOLPH ARONSON seconded the adoption of the report.

Mr. MARTIN WOOD supported the motion, and said he should like to acknowledge the value of the report, and the success of the Society's operations during the year. At the same time he was sorry to see that the effort to enlarge the operations of the Society had been unsuccessful, although he quite appreciated the stand the Council had taken in the matter. He hoped the older and more wealthy members of the Society would bear the matter in mind, and that means would be forthcoming for providing the Society with a suitable building. The Society, he said, was an Institution of very high value, higher in proportion to the demands upon it to carry on its work. It was true that there were many competing Institutions, which took up special branches of science; but the members would see that the Society still held its place with the rest of them, and he hoped there was some prospect of the Society finding a suitable site in the metropolis. He thought if the Council would adopt his suggestion of a sliding scale of payments for life composition, it would tend to increase the number of members, as a certain number of the senior members who now drop off every year would thereby be retained. It was very satisfactory to the members to learn of the continued increase in the examinations. He had always felt that the examination work kept the Society in touch with the kingdom at large, and anything that could be done to strengthen that feeling should in his opinion be kept up. Referring to the paper by Mr. Arthur Lee on "The British Canals Problem," he said he wished the Council, in view of the steps which the Society took in 1888, could have seen their way to have taken some practical action in this matter. He also drew attention to the hour of the Annual General Meeting, and expressed the opinion that if it could be held in the evening it would be a good deal better attended.

Mr. JOHN HUME referred to the remarks of Mr. Martin Wood as to increasing the number of members, and suggested that each member of the Society should endeavour to get a friend to join. He said

he had tried the plan himself, and had found it comparatively easy. He thought if the members would bear the matter in mind, and speak to their friends about it, they would be astonished at the number of people who were quite willing to join the Society.

The adoption of the report was then agreed to.

The CHAIRMAN moved a cordial vote of thanks to Sir Henry Trueman Wood (the Secretary), Mr. Henry B. Wheatley (the Assistant Secretary), and the other officers of the Society, which was seconded by SIR OWEN ROBERTS, and carried unanimously.

The SECRETARY returned thanks for this expression of confidence in himself and in the other officers of the Society.

The ballot having remained open for one hour, and the Scrutineers having reported, the CHAIRMAN declared that the following had been elected to fill the several offices. The names in *italics* are those of members who have not, during the past year, filled the office to which they have been elected.

PRESIDENT.

H.R.H. the Prince of Wales, K.G.

VICE-PRESIDENTS.

H.R.H. the Duke of Connaught and Strathearn, K.G.	*Francis Elgar, LL.D., F.R.S.*
Duke of Abercorn, K.G., C.B.	Robert Kaye Gray
Sir William Abney, K.C.B., D.C.L., D.Sc., F.R.S.	Sir Charles Augustus Hartley, K.C.M.G.
The Lord Chief Justice, G.C.M.G.	Lord Kelvin, O.M., G.C.V.O., D.C.L., LL.D., F.R.S.
Sir James Blyth, Bart.	Sir William Lee-Warner, K.C.S.I.
Major-Gen. Sir Owen Tudor Burne, G.C.I.E., K.C.S.I.	*Rt. Hon. the Earl of Onslow, G.C.M.G.*
Sir William Crookes, D.Sc., F.R.S.	Sir William Henry Preece, K.C.B., F.R.S.
Lord Curzon of Kedleston, G.M.S.I., G.M.I.E.	Sir Walter S. Prideaux
Lewis Foreman Day, F.S.A.	*Sir Owen Roberts, M.A., D.C.L., F.S.A.*
Sir James Dewar, M.A., LL.D., D.Sc., F.R.S.	Sir Marcus Samuel, Bart.
	William Thomas Shaw
	Alexander Siemens
	Sir John Wolfe-Barry, K.C.B., F.R.S.

ORDINARY MEMBERS OF COUNCIL.

Sir Steuart Colvin Bayley, K.C.S.I., C.I.E.	William Bousfield, M.A., LL.D.
Sir Mancherjee Bhownaggree, K.C.I.E., M.P.	*Michael Carteighe*
Henry Graham Harris	*William Charles Knight Clowes, M.A.*
Col. H. C. L. Holden, R.A., F.R.S.	*Hon. Richard Clere Parsons, M.A.*
Colonel Sir Thomas Hungerford Holdich, R.E., K.C.M.G., K.C.I.E., C.B.	Sir Westby B. Perceval, K.C.M.G.
	Dr. Boverton Redwood, F.R.S.E.
	Prof. John Millar Thomson, LL.D., F.R.S.

TREASURERS.

Sir George Birdwood, K.C.I.E., C.S.I., M.D., LL.D.	Carmichael Thomas

SECRETARY.

Sir Henry Trueman Wood, M.A.

On the motion of the CHAIRMAN, a vote of thanks to the Scrutineers was carried unanimously.

Sir THOMAS HOLDICH, K.C.M.G., K.C.I.E., C.B., proposed a vote of thanks to the Chairman for his services in presiding at the meeting, and also as Chairman of the Council during the past two years.

The motion was seconded by Mr. ROBERT KAYE GRAY, and carried unanimously.

The CHAIRMAN acknowledged the vote of thanks.

The meeting then adjourned.

INDUSTRIAL REVIEW OF NEW ZEALAND.

Government Blue-books and statistical returns generally may be said to develop their highest usefulness when they portray the subject of which they treat from the greatest possible number of aspects. One particular return in the latest statistics for New Zealand (for 1903)* is of great interest as, in addition to dealing with external trade, it gives the number of manufactories, works, number of hands engaged, value of manufactures produced, as well as the approximate value of land, buildings, machinery, and plant. The following are some brief abstracts relating to the condition of the more important local industries.

Preparation of Animal Food.—Among the various sub-headings that of meat freezing and preserving is of chief importance, some 2,221 hands (male and female) finding employment in 34 factories, and receiving in wages, in 1900, the sum of £199,725. The total value of the capital invested amounted to £893,720, while the value of manufactured produce
